PASSENGER car bodies with a compartment containing the top when down are no novelty, though previous to the war this construction was not very general in Europe. This practice in body design now seems to have "caught on," and several of the most recent foreign cars of which details have reached this country embody this feature. We have in mind particularly the Austin 20, recently described, and a Mercedes with body by Forrler of Strasbourg.

It is rather difficult to believe that this construction will ever come into general use here. What need is there for stowing the top away in this manner, anyhow? To some people the folded top with its cover extending to the rear of the car may appear obtrusive, but we do not believe that the average person sees anything objectionable in it. It may be possible to design an attractive-looking body with a top compartment, but those that we have seen so far certainly do not possess this attribute. Not only are the bodies with top compartment less attractive than conventional up-to-date designs, but the tops designed to go into these compartments are very ungainly when up.

Possibly the inclosed top is an outgrowth of the plan to streamline the whole body. If so, it seems this idea has been carried to excess.

Preservation of the top from wear can hardly be an object. When covered with a boot or case of waterproof material and held from rattling by a suitable holder the top is well protected.

Our manufacturers in their search for novelty have often been inclined to adopt European practices without convincing themselves of the merits of these practices. In the case of the top compartment it will be well to observe great caution.

Direct Selling in Foreign Lands

THE consensus of opinion among more than 500 American business men who participated in the sessions of the foreign trade convention was that direct selling in foreign lands is the only course to permanent foreign trade.

By direct selling they meant selling through branches in foreign countries, or directly through foreign jobbers, or dealers, or exclusive foreign agents.

In any or all of these three methods of direct selling there is the one underlying fundamental, namely, that you are doing business direct with the man who is meeting the consumer in the foreign country. This is the essential, the one necessary, it might be said the imperative part, of the transactions between manufacturer and consumer in successful foreign trade.

The branch-house method was conceded to be the best one although very expensive at first. The branch manager should be an American citizen, and preferably one who has been with the home company for many years, who is a living embodiment of the spirit of the company and who knows intimately the organization in every detail. Such a manager, with a staff picked in the foreign country in which he is doing business, will be qualified to handle foreign trade as it must be handled to make it permanent.

Where the exclusive agent is used as a representative abroad he must be an agent who is a recognized factor in the line he represents. The exclusive agent of an American tire company in London must be a recognized tire man in Great Britain. That is the first requirement. After this, it is imperative that the American maker give much assistance in getting the agent started in business with his line. This is best done by one or perhaps two representatives of the manufacturing company going to London and remaining several months until the business is well launched.

These representatives see that the exclusive agent gets started right—that he knows the fundamentals of the manufacturer's business policy; that he knows every detail of the merchandise; that he knows the spirit and rule of the company's service system; that he knows the future plans of the company. Such a selling connection, established in this way, is next best to a branch.

In direct selling the personal as well as business characteristics of the several countries must be studied individually. A blanket policy of studying European characteristics will not assure good foreign trade in a single European country. The business fabric of each country must be intimately understood. So must the social structure. This is specially true in the older world and also in Spanish speaking countries where a well-established acquaintanceship is a prerequisite for business.

In some countries a certain portion of business can be designated as clean business and another portion as tainted business. The manufacturer must understand this. By direct selling methods there is a possibility of some control over the taking of tainted business, whereas with what might be known as indirect selling there is not a possibility of the manufacturer protecting himself by any form of control in taking any of this kind of business.

By direct selling some control of the advertising of a product in foreign countries can be had. In fact the manufacturer should co-operate with the foreign seller of his product in this particular, and must realize that just as he gives his home distributers and retailers assistance by his national advertising campaigns so he must give his like assistance to his exclusive agents or jobbers in foreign trade.

This advertising must be intelligently done and not blindly dictated from the home office. There are too many cases where the home advertising company insisted on writing the copy for foreign consumer sales, which proved a dismal failure because the local conditions of the foreign country were not understood. The home advertising organization can give assistance. It can furnish copy that breathes the spirit of the home merchandising policy, but there should be no arbitrary instructions merely to translate the copy and use it. The only instructions should be to use the spirit of the copy and express it so that it will be understood in the local field.

No advertising man can write selling copy for a people living 3000 or 6000 miles away, whose country he has never visited, whose social customs he has not studied at first hand, whose business methods he has only read of and whose language he has never spoken.

Service requirements constitute one of the strongest reasons for direct selling connections. Good service is impossible where the manufacturer is not known to the consumer, as too often happens with indirect selling methods. Service in the foreign field is immeasurably more important than in the domestic market.

The carrying of an adequate stock of spares in foreign countries is a most important factor in continuing and developing foreign trade. The branch house provides the best opportunity to do so, but with the foreign jobber and the exclusive agent good representation in this particular is possible, but with a greater degree of effort. The branch house managed by a factory representative is as closely in touch with the foreign consumer as the home factory. The stock of spares in the foreign branch can be handled as methodically as the factory maintenance department. When free service has to be given the factory man is there to look into the merits of the case. And this also applies to the replacement of defective parts.

In direct selling the error must not be made of placing the business in one country under a jobber or agent in some other country. Some form of direct representation should be established in every country where it is expected to do business.

Foreign Propaganda for N.A.C.C.

Chamber to Send Investigators Abroad and Advertise American Cars—Propose National Truck Shows

DETROIT, May 6—Active steps in spreading trade propaganda of the American motor car in foreign countries, and a move toward the holding of national truck shows in New York and Chicago, were taken at the meeting of the directors and truck committee of the National Automobile Chamber of Commerce here to-day.

The N. A. C. C. plans to send special investigators abroad immediately for the purpose of investigating the foreign markets, and an extensive world-wide advertising campaign will be carried on to exploit the merits of the American-made car and truck.

The automobile industry in 1916 exported products in excess of $120,000,000 and the N. A. C. C. is not only anxious to maintain this business but to enlarge it. Growth is sure to come through the recognition of the value of automotive transportation due to the extended use of the American motor truck and passenger car during the war.

It is expected by this means to increase materially the export ratio to the total business. At the present time it is about 10 per cent. Details on these matters will be threshed out in New York on June 6 at a meeting of the export managers, when C. C. Hanch of the N. A. C. C. will have returned from Europe.

The truck division has taken under advisement the holding of truck and tractor shows the same weeks as the national automobile shows. Plans for the national truck shows to be held in New York and Chicago in January were outlined by the Show Committee.

The special committee on truck standardization headed by D. C. Fenner, and working in co-operation with the Society of Automotive Engineers, made substantial advances in its plans for new standard load ratings and various other matters concerning truck construction, to the advantage of users by reducing manufacturing costs and lowering selling price and at the same time adding to the efficiency and carrying capacity of the vehicle itself.

While truck business was slow in January and February, reports read at the meeting show that March and April business was reaching normal with excellent future prospects. Indications point to a great increase in truck sales in 1919.

Reports on legislation throughout the country show a marked degree of fairness on the part of state legislation for trucks. State bodies are becoming convinced of the necessity of hard-surfaced roads for their use and for motor travel in general. This is evinced in the fair attitude by lawmakers as to registration fees and weights permitted on the road. The general impression is to favor 25 cents per horsepower and 25 cents per 100 lb. as proper legislation, with 28,000 lb. as a maximum and not more than 800 lb. of weight permitted for each inch width of tire.

In attendance at Tuesday's meeting were J. Walter Drake (Hupmobile), chairman; W. D. Sullivan (G. M. C.); C. W. Williams (Hudson); J. J. Rathbun (White); H. M. Robins (Dodge); J. D. Dort (Dort), and number of export managers from Detroit plants.

Will Not Lift French Embargo

WASHINGTON, May 6—There is no truth in the reports that French import restrictions are to be completely lifted on June 1. A cablegram received by the Department of Commerce is to the effect that there may be some slight relaxation at that time, but there is no contemplated rescinding in a body of existing restrictions. Rumors were to the effect that the demand for textiles and automobiles in France would force the government to remove the import embargo.

International Harvester Buys P. & O. Plow

CHICAGO, May 7—The International Harvester Co. has purchased the Parlin & Orendorff Co., Canton, Ill., maker of P. & O. plows. The International company takes over the Parlin & Orendorff Co., with its ten branches, on July 1.

According to the financial report of the International Harvester Co. for the year ended Dec. 31, 1918, which includes operations of the International Harvester Co. of New Jersey and the International Harvester Corp., from Jan. 1, 1918, to Sept. 19, 1918, when the two companies were merged into the present organization, the combined surplus in 1917 amounted to $12,659,000. The 1918 surplus of $14,985,325 is $2,326,000 in advance.

In 1918 the company charged off $10,478,000 as depreciation of its assets in Russia. With the $13,727,000 charged off in 1917, the deduction for the 2 years amounts to $24,205,000. The gross income, after providing for taxes, is $31,648,850 and the surplus account, which was $61,051,337 in 1917, was increased at the end of 1918 to $68,036,662.

Vacuum Tank Patents Not Infringed

Previous Decision Freeing Weinberg of Stewart-Warner Infringement Claim Upheld

CHICAGO, April 7—The patent situation on vacuum tank methods of fuel feed made another step toward final solution when the Court of Appeals, April 30, upheld the previous decision of the United States District Court that the Thermo-Vacuum system based on Fred Weinberg's patents does not infringe the Webb-Jay patent on which the Stewart-Warner tank is built.

While directly affecting only the situation as between Stewart-Warner and the Thermo system, it also indirectly may influence the final decision on the appeal of Stewart-Warner from the decision of Judge Westenhaver last winter, which held that the Sparton tank, manufactured by the Sparks-Withington Co., infringes the Stewart-Warner patents only on two points of a series claimed.

After Judge Sanborn handed down his decision, April 20, 1918, in the United States District Court, holding that the Thermo-Vacuum system brought out by Fred Weinberg of Detroit was not an infringement on the Webb-Jay patents under which Stewart-Warner is licensed to manufacture the Stewart-Warner vacuum tank, Stewart-Warner appealed the case in the district Court of Appeals, and April 30, 1919, in this court, Judge Baker affirmed the decision of Judge Sanborn.

This court held that pumping a liquid, either gasoline or water, was an old process, and that while the Stewart-Warner patents were valid, the Weinberg tank was not an infringement, as in both devices the whole apparatus combined with the engine was broadly a pump.

On Dec. 10, 1918, the Webb-Jay patents on the Stewart-Warner vacuum tank were held infringed by the Sparton vacuum system, made by the Sparks-Withington Co. In a decision handed down by Judge Westenhaver, in the United States District Court, also in Chicago, again the Stewart-Warner patents were held valid. Two of the 14 or 15 claims of Stewart-Warner were held infringed. The other claims for which an infringement decision was asked were upheld in a decision that the Sparton tank did not infringe.

This has been carried to the Court of Appeals by Stewart-Warner, and should this court be influenced by the recent decision of Judge Baker in affirming Judge Sanborn's decision on the Weinberg patents, and rule that the Sparton tank was

Automotive Industries

not an infringement on the Jay patents, then Stewart-Warner may carry both cases to the Supreme Court. If the decision of Judge Westenhaver is affirmed, then Stewart-Warner will probably not carry the Weinberg case to the Supreme Court, as they feel the Thermo-Vacuum system is not a real competitor.

Air Service Establishes Landing Fields

WASHINGTON, May 6—The Air Service of the U. S. Army has inaugurated a plan to establish landing fields in all parts of the United States in co-operation with municipalities, according to announcement by Maj. Gen. C. T. Menoher, and has issued specifications which are in accord with the army regulations. Together with this announcement, the Air Service states that it has already designated 32 cities and towns from the Atlantic to the Pacific where it hopes to secure the aid of the municipalities to establish and organize a national system of air lanes. Landing fields will be of four classes.

The Air Service will select landing fields in co-operation with municipal representatives. Neither the Air Service nor the Post Office Department will deal with any private associations in this matter.

At present the government will cooperate only in the establishment of municipal flying fields at the cities where the Post Office Department establishes aerial mail stations, or where the Air Service cross country routes require intermediate stations. The following cities have already been designated and flying fields will be built at each:

Boston, Mass.	Columbus, Ohio
New York City, N. Y.	Tucson, Ariz.
Richmond, Va.	Phoenix, Ariz.
Raleigh, N. C.	Yuma, Ariz.
Columbia, S. C.	Bakersfield, Cal.
Augusta, Ga.	Fresno, Cal.
Macon, Ga.	Buffalo, N. Y.
Atlanta, Ga.	Syracuse, N. Y.
Kissimmee, Fla.	Albany, N. Y.
Mobile, Ala.	Columbus, N. M.
New Orleans, La.	Kansas City, Mo.
Baton Rouge, La.	Oklahoma City, Okla.
Beaumont, Texas	Uniontown, Pa.
Flatonia, Texas	Daytona, Fla.
El Paso, Texas	Cleveland, Ohio
Texarkana, Texas	Chicago, Ill.

Although the government is confining itself to the establishment of these municipal landing fields, there is no restriction on other landing fields at cities and towns where local conditions or local initiative warrant it. The government will furnish an expeditionary steel hangar to be erected at the expense of the municipality.

It is understood also that the landing fields will be prepared at the expense of the municipality, which will also bear the expense incurred in the procurement of personnel and the maintenance of the field and equipment exclusive of airplanes.

Treasury Department Issues Rulings on Excise Taxes

Official Interpretations of the Law as It Applies to Automotive Products—Regulations Covering the Manner of Calculating the Amount of Tax and How It Is to Be Collected—What Is and Is Not Taxable

HIGH LIGHTS IN THE TAX REGULATIONS

TAX became effective Feb. 25, 1919.

The tax is on the actual sale.

If the tax is included in the sale price, the tax must be computed on the increased price.

Discounts for cash made subsequent to the sale cannot be deducted. When a rebate is made in return for a quantity purchase that extends over a period of time a deduction of the rebate is allowed to be made for the month when the final price is determined.

Commissions to agents or other expenses of sale are not deductible.

A maker of a body pays a tax. A maker of a chassis pays a tax. The assembler of both pays a tax, but can credit himself with the amount of the tax imposed on the body and chassis makers.

Where makers have agencies in which they have financial interest the agency pays the tax.

Tractors are not taxable even if sold in combination with trailers.

Trailers are not taxable unless they are of the type that forms the rear part of a car or truck.

When parts are sold by a maker to a jobber and in turn to a producer of cars, the manufacturer of the parts pays the tax.

Where a maker of parts or accessories sells them to a maker of cars, trucks or motorcycles, the manufacturer of the completed article pays the only tax.

If a manufacturer is engaged in both wholesale and retail business he bases the tax on the wholesale prices when sold at wholesale and on the average wholesale price of the articles sold at retail.

There is no tax for cars, trucks or motorcycles sold for export, provided they are exported within six months of the date of sale.

WASHINGTON, May 6—Regulations and interpretations of the income taxes as they apply to automotive products have been completed by the Treasury Department.

The rulings are not sufficiently complete to allow definite understanding of all of the problems that have come up in relation to the tax on automotive products.

In some instances they are exceedingly vague, as, for example, in the statement that if any doubt exists as to whether an accessory should be taxed, it will be determined by the fact that it is sold to an automobile accessories dealer by the manufacturer, which ruling is completely reversed by a following statement to the effect that a monkey wrench sold for general purposes is not subject to a tax.

On all such matters it will be necessary to secure definite special rulings from the Treasury Department. This, judging from the length of time taken to compile the present regulations, will occupy some few months, and in the meantime it will be necessary for the manufacturers to pay the tax and depend on a later ruling for securing credit where credit is due from the government.

That a tax can be imposed more than once on the same commodity is shown in the case of the assembler of automobiles who buys chassis from one maker and bodies from another. Each of the three producers has to pay a tax although certain credits are allowed the assembler as specified below.

Where an automobile maker has an agency in which he has a financial interest he does not pay a tax on the cars delivered to that agency for sale until the agency makes the sale. The agency then pays the tax. This is apparently done because of the difficulties that would arise if a manufacturer shipped a number of passenger cars to one of his branch retail establishments and had to pay a tax on them, whereas they have

Rapid Increase in Car Production

7084 Cars a Day Turned Out in Michigan and Ohio During April—Demand Well Ahead of Output

Daily car production figures for April are as follows:

Car	Jan.	Feb.	March	April
Buick	100	400	450	500
Briscoe	30	50	50	75
Barley	...	4	10	12
Cadillac	55	60	80	100
Chalmers	30	65	70	80
Chandler	...	50	90	60
Chevrolet	...	300	350	700
Columbia	8	10	15	18
Dodge	300	375	400	500
Dort	40	65	70	100
Ford	1,300	2,000	2,400	3,000
Harroun	4	4	10	15
Hudson	30	50	50	100
Hupp	38	55	65	75
King	...	4	10	10
Liberty	15	15	25	30
Maxwell	150	150	220	250
Oakland	160	160	200	...
Olympian	4	5	10	12
Oldsmobile	...	110	140	140
Overland	320	400	422	600
Packard	...	...	1	25
Paige	50	50	55	70
Paterson	10	10	10	15
Jordan	...	...	...	12
Reo	100	100	125	125
Saxon	10	50	65	50
Scripps-Booth	20	40	45	45
Studebaker	150	150	175	200
Essex	30	50	50	100
Grant	25	35	50	50
Total	2,984	4,822	5,741	7,084

DETROIT, May 3—Production figures for Michigan and Ohio show that approximately 7084 automobiles were made daily during April. This is an increase of 1353 cars over the daily March production of 5741 cars and nearly 2½ times greater than the production of January, when 2984 machines were turned out daily.

From the unprecedented sales orders in the hands of manufacturers it is evident that if every factory could double its production every car would have an immediate sale. The demand for cars is greater to-day than at any other time in the history of the automotive industry. The demand exceeds the production of practically every company from 33⅓ to 70 per cent.

If the majority of the plants increase production during May, as many are now endeavoring, daily production for the present month will average approximately 10,000 cars and the month of June will see it reach a high mark under present manufacturing conditions. So great is the demand that many plants are rushing work on new building units. This is noticeably true of the Jordan Motor Car Co., Cleveland, which proposes to build a new plant greater than its present establishment. The Hudson Motor Car Co. is pushing work to the limit on new units to handle Essex production. Scripps-Booth will have a new factory this fall. General Motors expansion plans call for greatly increasing the manufacturing facilities of Buick, Oakland, Oldsmobile, Cadillac, Chevrolet and its other passenger car units.

Production during April was boosted despite the handicap of a tight material market and labor difficulties. All parts makers are experiencing an equally great rush of business and are unable to keep up with orders. As a result the companies depending upon them for parts are obliged to limit production to their parts supply. The parts makers have not switched from a war to a peace basis with the same rapidity of the motor car companies, and as a result are just beginning to reach capacity production. They have been harder hit by the hold-up of funds on government contracts, but this disadvantage has lately been overcome by the willingness of the government to advance 70 per cent of the money they claim is due them, leaving the remaining 30 per cent to be paid when the contract claim is finally approved at Washington.

The Detroit car manufacturers have encountered considerable difficulty in obtaining a steady flow of castings from the foundries, due to labor trouble. During April, 13 Detroit foundries were tied up by strikes. Seven are still affected, but six of the strikes have been settled. The companies all have had trouble in various departments, but in almost every instance the workers returned to work in the course of a few hours. However, suspension of operations for but a brief period had a marked effect on production, causing the April output of a number of concerns to fall short of schedule.

Packard Running Up Production

DETROIT, May 2—The Packard Motor Car Co. is running up its production rapidly, producing 200 passenger cars and 750 trucks in April. In May 350 passenger cars will be turned out, while June and July production calls for 500 cars monthly.

Paterson Turning Out 15 Machines a Day

FLINT, May 2—The Paterson Motor Car Co. is running 15 machines daily and is preparing to increase this production. The company has encountered some difficulty in securing material, but this situation has been greatly relieved within the last three weeks.

Harroun Picking Up on Production

DETROIT, May 2—The Harroun Motors Corp. of Wayne, Mich., is now running 15 cars daily. Within the next 30 days the company hopes to produce 25 cars per day.

The assembly department of this plant is still choked with government machinery, which has not yet been removed. Until this machinery is taken out production will be greatly curtailed.

Chandler to Make 3000 in June

CLEVELAND, May 2—The Chandler Motor Car Co. hopes to produce 2500 machines this month and 3000 in June. At present it is running approximately 16 cars daily.

Detroit Now Faces Labor Shortage

50,000 Skilled and Unskilled Workers Needed—Active Efforts to Enlist Men in Other Centers

DETROIT, May 2—There is a shortage of 50,000 skilled and unskilled workers in Detroit and an advertising campaign is being conducted in 69 cities where a surplus is reported. The larger companies are going even further, and are sending field representatives into these localities to head the unemployed toward Detroit. An example is the Packard Motor Car Co., which could use 500 more men immediately. This company has sent men to Camp Custer and to Great Lakes Naval station offering immediate employment to all service men the minute they are released from service.

Every company has more business than it can handle and the cry for men is becoming greater daily. As a result wages are beginning to go up, and it is predicted that within a month the scale will be greatly increased everywhere. The great obstacle which the companies must solve is the housing situation. This is daily becoming more critical. Rents are soaring and homes are at a premium. The companies are meeting this situation manfully and are not only contemplating house construction for employees but are aiding in the financing of a $5,000,000 corporation which proposes to start work at once on several thousand homes.

Within three months Detroit's labor problem has swung from one extreme to the other. In February between 30,000 and 50,000 men were without jobs, and the word was sent out to stop the flow of labor to Detroit. This warning had a noticeable effect, with the result that Detroit has a huge shortage.

The first of May saw labor demonstrations of a minor nature in Detroit. There are many strikes on and a universal cry for more wages. The big automotive concerns are not greatly affected, however. Some of them have suffered small walk-outs, but the trouble is usually settled in a few hours and the men are back on the job. While wages have advanced generally in the last three months, the advance is not keeping pace with the increasing cost of living, which still continues to soar. The increase in the wholesale cost of all commodities between August 1, 1914, and April 1, 1919, is 72 per cent.

Apperson Adopts 25 Per Cent Profit Sharing

KOKOMO, IND., May 6—Twenty-five per cent of the profits of the Apperson Brothers Automobile Co. for 1919 will be distributed among its employees who have been with the company throughout the year, proportionate to the amounts paid to each during the year. Announcement of the plan was made this week by the company to all employees.

The distribution of the employees' share in the profits will be made at the same time that dividends are determined for the stockholders, and the amount will be one-quarter of the net profits, after deducting the 8 per cent allowed by the Federal Income Tax law on invested capital. Every employee of the company, in whatever capacity, will share in the distribution provided he has been with the company throughout the year, and still in its employ at the time of the profit distribution.

—

Shop Committee to Represent Overland Employees

TOLEDO, May 5—Details of a plan whereby Toledo employees of the Willys-Overland Co. will elect a shop committee to represent them in all negotiations with the company will be announced soon. In a preliminary statement the company explains that a committeeman will be elected by secret ballot from the various departments, and that these committeemen will form a joint committee with representatives of the managament.

When the plan is in operation the workers will have a direct voice in determining working conditions, questions of safety, health, discipline and unfair treatment, and in settling any differences that may come up between them and the company. A general board of adjustment also will be organized, composed of both representatives of the employees and the company, to which cases may be appealed. Every employee, male or female, in service 3 months may vote for his choice of representative.

—

Wilson Foundry Makes Bonus Awards

PONTIAC, May 3—The Wilson Foundry & Machine Co. has announced a plan of continuous service awards for working men. The amount of these bonus distributions aggregates $250,000 a year. The plan is based on efficiency and continuity of service.

Every employee working 6 months without absence except for recognized reasons will be entitled to participate in the payments made quarterly. The first checks were distributed to-day in addition to the quarterly payments, and the annual one will be made rewarding long continued service and efficiency.

—

White Capital Raised to $20,000,000

CLEVELAND, May 5—An increase in the capital of the White Motor Co. from $16,000,000 to $20,000,000 was voted at the annual meeting of the company's stockholders. Its regular quarterly dividend of $1 per share was declared, payable June 30 to stockholders of record June 14. All directors and officers were re-elected.

—

Maxwell Sales Ahead of Production

DETROIT, May 5 — The Maxwell Motor Car Corp. is running between 200 and 250 cars daily. Sales are exceeding production of this company by 33 1/3 per cent.

Detroit Labor Trouble Continues

26 Unions Filed Demands on May 1—Several Strikes Indirectly Attack Ford Company

DETROIT, May 5—Labor trouble in Detroit continues to grow in scope. On May 1, as predicted last week by AUTOMOTIVE INDUSTRIES, 26 unions filed demands for more wages and shorter hours.

The outlaw United Automobile, Aircraft & Vehicle Workers of America called strikes in several plants. Altogether, approximately 12,000 workers of different unions went on strike at the plants of Wilson Body Co., Liberty Starter Co., Detroit Brass Works, Murphy Iron Works, L. A. Young Industries Co., Bowen Products Corp., Aluminum Castings Co., Commonwealth Brass Co., Solvay Process Co. The men returned to work when general wage demands were met by the respective companies. Strikes in 7 out of 13 foundries still continue. No settlement has yet been reached in the Wadsworth Mfg. Co. strike.

A number of strikes were averted by compromise agreements. The Electrical Workers, who threatened a general walkout, postponed action until May 17 at the request of the strike committee, who said a settlement would probably be reached by that time. The Typographical Union settled with the employers on a $36 weekly scale with 48 working hours a week. This union asked for $42 salary and 42 hrs. a week.

While the United Automobile, Aircraft & Vehicle Workers of America are strongly organized in Detroit, attempts of this organization to form a local branch in Flint, home of Buick, Chevrolet, Dort and Paterson automobile companies and scores of other automotive concerns, last week met with a rebuff. The Flint Federation of Labor has gone on record as bitterly opposed to this new organization, branding it as a "pirate organization not affiliated with the American Federation of Labor, radically socialistic in its demands and a sister of the I. W. W." The Flint unions are preparing to wage a bitter fight against the entry of the outlaw organization in that city.

In Detroit it is apparent that labor's indirect attack is at the Ford Motor Co. The walkout in the Liberty Starter Co.'s plant, practically halting all work, has all but cut the Ford company out of starting devices for its sedans and coupés. The Liberty company is devoted exclusively to the manufacture of starters for Ford cars. The Wadsworth Mfg. Co. is working entirely upon Ford sedan and coupé bodies. Its production has dwindled from 250 bodies daily to less than that number in three weeks. The Wilson Body Co. is also making Ford bodies in large numbers and its production has been badly hampered.

At the Liberty Starter plant the machinists have gone out. The union asks the reinstatement of certain employees discharged for labor activities, the elimination of the check system of wage payment, the elimination of "gum-shoe" men, service men to be restricted to exits, adjustment of conditions in some departments by officials meeting with the department committee, a minimum wage of $6 per 8-hr. day for men and women alike, a 42-hr. working week, time and one-half for overtime up to four hours, double time for a longer period; double time for holidays and Sundays, 80 cents per hour for tool specialists, 90 cents per hour for tool makers.

At the present time strikes have not affected the automobile companies directly, being confined entirely to parts and body makers. Some of the automobile plants have had a little trouble in some departments, but it was only temporary and production was not materially affected.

—

Wages Increase 32.5 Per Cent in February

WASHINGTON, May 5—Wages in 47 automobile factories increased 32.5 per cent for the month of February, 1919, as compared with February, 1918, while the number employed increased only 0.8 per cent. Forty-seven manufacturers reporting stated that they employed 109,583 workers in February, 1918, for $2,445,176, as compared with 110,472 in February, 1919, for $3,240,057. The increase of February as against January, 1919, although not so high, is marked. Forty-six manufacturers reporting for February stated an employment of 108,546 against 107,741 in 1919, an increase of 0.7 per cent, while the pay roll for February, 1919, totaled $3,197,307 as against $2,963,982 for January, 1919, an increase of 7.9 per cent.

Company Formed to Meet Akron Housing Scarcity

AKRON, May 5—Akron has launched a campaign to raise two and one-half million dollars for the purpose of building homes for the working men. The housing problem has been very serious here since early spring, when the factories expanded their activities and greatly increased their working forces. This project is being fathered by the housing committee of the Chamber of Commerce and has been endorsed by the heads of all of the city's industrial plants.

The company to be formed will work along three lines; it will let money on first and second mortgages at reasonable interest to men who want to build, supplementing the home financing done by banks and savings and loan companies in this respect.

The company will build houses to rent. It will encourage renters, however, to buy. Rentals charged will be high enough only to carry the investment and overhead expense. The effect of a lot of such houses for rent will, it is thought, bring down the exorbitant rents now charged in many sections.

While the company will be legally a corporation for profit, it does not expect to make more than 6 per cent, and the stockholders may have to content themselves with 5 or 4 per cent.

The company, which is as yet unnamed, will have an authorized capitalization of $5,000,000, but only half of this amount will be issued at this time. The Goodyear, Goodrich and Firestone Tire companies have already subscribed for half a million apiece, so there will be just a million dollars' worth of stock to be floated in the city generally. A campaign will be put on to raise this money.

—

General Motors to Become Billion Dollar Corporation

NEW YORK, May 5—General Motors will likely become a billion dollar corporation. At the meeting of the board of directors in Wilmington last week, President W. C. Durant stated that the board of directors had recommended an increase in the debenture stock to $500,000,000 and in the common stock to $500,000. The increase will be passed upon at a special meeting to be held on June 12.

W. P. Chrysler is elected first vice-president and H. H. Bassett was added to the Board of Directors and appointed general manager of the Buick division. Both Bassett and F. W. Hohensee, general manager of production of the Chevrolet division, were elected vice-presidents. The complete list of officers and directors follows: President, W. C. Durant; first vice-president, W. P. Chrysler; vice-presidents, H. H. Bassett, A. G. Bishop, R. H. Collins, W. L. Day, J. A. Haskell, A. W. Higgins, F. W. Hohensee, R. S. McLoughlin, C. S. Mott, J. J. Raskob, A. P. Sloan, Jr., Edward VerLinden, F. W. Warner; secretary, T. S. Merrill; treasurer, H. H. Rice; comptroller, M. L. Prensky.

Oakland Adopts 48-Hour Week

PONTIAC, MICH., May 5—The Oakland Motor Car Co., beginning May 8, will put its entire plant on a 48-hr. a week basis. The plan calls for beginning at 7 a. m., a 50 minute noon hour, and closing at 4.30 p. m. The usual half-holiday Saturday is allowed. To keep wages near the old standard certain increases in piece rates and hourly rates have been allowed.

—

Jordan Capital Jumps Over Million

CLEVELAND, May 6—The capital stock of the Jordan Motor Car Co. is to be increased to $1,200,000, 7 per cent preferred, and 12,000 shares of common with no par value, authorization for the increase having been voted at a special meeting yesterday. The company will erect several new buildings and will make a conservative increase in production.

Last year Jordan business totalled $8,000,000 on a capital of $300,000. The new stock issue will be in the form of a 50 per cent stock dividend. Edward S. Jordan retains control of the company.

6000 Machinists Quit at Overland

Demand 44-Hr. Week, Wage Increases and Elimination of All Piece Work

TOLEDO, May 6—The International Machinists Union called a strike at the Willys-Overland Co. plant at 3.30 Monday afternoon. Approximately 6000 machinists quit at that hour, refusing to work until 4.06 o'clock, the closing hour decided upon by the company. There are 6665 men at work in the plant to-day. The strikers have picketed the factory, and have declared they will resist to the utmost the effort to put a 48-hour working week into effect. There has been no rioting. Automobile production has been considerably curtailed. Production in some departments is at a standstill. Just how much the daily output has been hit will not be known for several days.

C. A. Earl, vice-president and general manager of the Willys-Overland Co., said to-day:

We are going to stand by the interests of the great mass of our employees. We are not going to let the radicals run this business. We have been trying for 6 weeks to reach an agreement with the Union. Every attempt has failed. This matter had to come to a head sooner or later and it is probably just as well that it be settled now as later. We are going ahead at any cost.

The Willys-Overland company to-day stands with absolutely clean hands and a clear conscience in its dealings with its employees. In its desire to promote harmonious relations with its workers, it has established a 50-50 profit sharing plan through which the first payment of the company distributed $415,000. The company has made a wage adjustment by which thousands of its employees received increases. The company has provided for an employees' representation plan by which every employee can present any grievance as to hours, wages or working conditions, with absolute certainty that a fair adjustment will be made. This company has asked its employees to work 48 hours a week, to co-operate with it in competing with others in the automobile industry, where hours range from 48 to 55 a week. The Willys-Overland presents this open record of its policy to demonstrate conclusively that fairness and justice have been the paramount considerations in all its dealing with its employees.

On March 27, the Willys-Overland Co. was presented with written demands by a committee of employees claiming to represent all the employees, when as a matter of fact many departments were not included. These demands, among other things, called for increases in pay of from 15 to 50 per cent for a 44-hr. week of 5 days of 8 hr. each and 4 hr. on Saturday; elimination of all piece work; double time for all overtime, with other restrictions referring thereto; a closed shop with a shop committee elected from certain sections of their employees without regard to the interests of other workers, and this committee to be elected outside of the company's plant, and such a committee to be recognized by the company for the adjustment of all grievances.

Their demands further provide that all physical examinations should be discontinued, notwithstanding that this practice has proven to be in the interests of the employee and has had the unqualified indorsement of governmental boards and national labor leaders. Other restrictions were imposed as to apprentices. With these demands there was not submitted, nor has there been since at the several conferences held between the company and this committee, one line of supporting evidence substantiating the fairness of the demands made or the practice of them in the automobile industry.

Meetings have been held from time to time whenever desired by the committee. The company has offered to lay before the committee its reasons in writing in support of the position that it has taken on the several questions at issue. The committee's answer in effect has invariably been: "It's not what the war and labor boards have done, it's not what constitutes an 8-hr. day. It's not what the other competing automobile companies are paying as wages nor the hours worked nor their piece work systems, but it's what we want or, in other words—COME ACROSS."

No weight nor attention was paid to the facts or given any consideration whatsoever that supported the position of the company. From the very outset the company officials made plain to this committee their attitude on the question of hours of work and the other conditions in question. Monday the committee refused to avail themselves of the representation plan or give it a single trial, even when they were told that the first work of this employees adjustment board could be a division of the 48-hr. week into six 8-hr. periods or the basic 8-hr. day.

It became very evident from the first that it was not the 8-hr. day that the committee desired, but a 44-hr. week. It has been made plain by the officials of the company, both through the shop paper and the public press, that the new classification of wage scale which has resulted in increases to thousands of Willys-Overland workmen, that any inequality in classifications or rates could be taken up and adjusted. They absolutely have refused to have anything to do with it.

The fact that for years in the arsenals and Navy Yards a system of grading and classification of employees has been in force with all the advantages that accrue to the workmen in a wage system of this kind received no consideration at their hands. The fact that time and a half overtime to be paid each day beyond the standard working hours did not interest them, notwithstanding many recent decisions of governmental boards recognized the practice of paying overtime only beyond the 48-hr. week. Nor did the representation plan, in which the employees are to elect half the members of the adjustment board, serve to interest them, nor to offer any indication to their minds of the company's fairness.

The company is manufacturing automobiles in a competitive field. The proposed 48-hr. week is as short as, or shorter than their competitors. Its wages are equal to or higher. The working conditions are equal to or better. The company has paid to its employees within the last few days the sum of $415,000 from the profits on the 50-50 plan for the first quarter of 1919.

The company has made a most careful survey and investigation of rates of wages paid in this industry, has installed these rates which range from a minimum of 40 cents to $1.10 per hr. for male employees. It has classified the workmen in an equitable and fair way and provided means of remedying, through the proposed employees' committees, any errors that might have occurred in this enormous task.

Last, but not least, they have provided a representation plan of taking up and correcting grievances and complaints, providing for a voice of their employees in all matters of wages, hours and working conditions.

With many concerns actually reducing wages and lengthening working hours, this company, in order to meet and maintain the fairest conditions in its plant, increased wages and announced a 48-hr. week for a period of at least 8 months.

The company is charged with the conduct of its business through its officials, who are responsible to the stockholders of the corporation, and to those loyal employees who appreciate what the company has done in this way of a profit-sharing distribution, representation plan and a wage increase.

The company proposes to stand to the end by those employees who desire to be fair and work squarely with them in partnership. It does not propose, nor can it permit, persons who are not its employees and who have no responsibility in the conduct of its business, to dictate its business methods or policy. The company appreciates the loyalty of its many thousand employees who refuse to believe the untruthful and misleading statements of outside agitators, and who are standing manfully by this company, and who have assured their foremen and department heads that they would not cease work as some did because of the threats and attacks made upon them.

The company wishes to emphasize the fact that there has been no lockout. Those who left work did so voluntarily and in defiance of the rules of the company.

Mr. Willys very much regrets that his profit-sharing plan, in the interest of his employees, should not be appreciated by some of them at the Toledo Plant, who have voluntarily forfeited additional profits that would have come to them in the next two distributions.—C. A. Earl, First Vice-President.

Treasury Department Issues Rulings on Excise Taxes

(*Continued from page* 1027)

not been actually sold since the manufacturer owns the retail establishment. The tax on the cars sold through the retail establishment of a manufacturer is based on the wholesale and not the retail price.

The interpretation to the effect that trailers are not taxable except when they form a composite part of a truck is apparently meant to apply to those units which are attached to a chassis to form the truck. Likewise the interpretation allowing for credit of taxes where rebates are made on quantity sales stretched over a period of time is probably intended for such manufacturers as Ford, which rebates its dealers after they have purchased a certain quantity of cars. The regulations regarding tractors do not specify farm tractors and apparently no tractor is taxable whether it is intended for farm or other use.

Taxes are effective on all articles sold or leased by manufacturers, producers and importers beginning February 25, 1919, regardless of the date of manufacture.

In the tax law the use of the word "manufacturer" means also "producer" or "importer"; the word "sale" or "sold" includes "lease" or "leased." The term "purchaser" includes the "lessee" and the word "person" includes "partnerships," "corporations" and "associations" as well as individuals.

The tax is imposed on the sale by the manufacturer and is measured by the price for which the automobile or article is sold.

The tax is on the actual selling price, not on the list price.

If the price of a taxable article is increased to cover the tax the tax applies on the increased price.

Discounts for cash made subsequent to the sale cannot be deducted when assuming the tax, but if the articles are sold over a period of time with an agreement for a quantity rebate this fact may be taken into consideration in calculating the tax when the rebate is made.

Commissions to salesmen or agents and other expenses of sale are not deductible from the price.

If an article is sold at the factory and the buyer pays the delivery charges from the factory f.o.b. freight cars, or if it is sold delivered at a price less delivery charges, to be paid by the purchaser, the charges need not be included in the price of the goods.

If the manufacturer sells f.o.b. consumer and himself pays the delivery charges he cannot make deductions.

If articles sold are returned and the sale entirely rescinded no tax is payable, and if paid it may be credited in a subsequent monthly return. If part of the articles sold at one time are returned and credit is allowed, the proportion of the tax to be credited will be only that proportion of the total tax paid which the amount allowed as a credit or rebate bears to the total sales price of all of the articles.

A manufacturer is a person who prepares a taxable article in marketable form.

Under this interpretation if there are several manufacturers, as, for example, if a manufacturer produces a body and another a chassis and these two are assembled by a third, each must pay a tax. However, the assembler can credit himself with an amount equal a tax he has already paid to the manufacturer of the body and of the chassis. It is necessary, however, for the assembler to keep records to clearly establish his right to this exemption.

When a manufacturer sells passenger cars or motor trucks to the government, the tax applies unless the government has supplied the manufacturer with all but a small portion of the parts used in the assembling.

There is no tax on motor driven vehicles used in intra-factory work at railroad stations, etc., where they are used to pull other vehicles. Motor trucks equipped as hook and ladder trucks are taxable.

Automobiles sold by a manufacturer and once taxable are not taxed when sold again unless the manufacturer accepts the return of the automobile and resells it after taking credit for the tax on the first sale.

Tractors are exempt even if sold in combination with trailers.

Accessories, tires, etc., sold to a dealer for the rebuilding of a used car are taxable.

Manufacturers of accessories when selling them to assemblers or manufacturers of automobiles must secure written certificates that the accessories and parts will be used in the manufacture of new cars or for free replacement under contract or guarantee.

Failure to possess such certificates will be considered sufficient to warrant demand of payment of tax by the government.

A "part" for a motor truck, motor wagon, other automobile or motorcycle is any article designed or manufactured for the special purpose of being used as or to replace a component part of the vehicle and which by reason of some peculiar characteristic is not such a commercial commodity as would ordinarily be sold for general use and which is not primarily adapted for use as a component part of the automobile or motor truck or motorcycle; consequntly bolts, nuts, screws, etc., are not taxable. Articles which would ordinarily be classed as commercial commodities become taxable when the design or construction adapts them for use as component parts of vehicles, as, for example, plates, jars and separators for automobile storage batteries are taxable when sold separately. A chassis is a part of an automobile, as is also a body, and is taxable at 5 per cent when sold separately regardless of whether it is a chassis for a passenger car or motor truck.

An accessory is any article designed primarily for use on a motor vehicle to add to its utility and is taxable whether or not it is essential to its operation.

Robes, goggles and lunch kits are not taxable.

Automobile trailers are not parts or accessories for automobiles, but rear portions of automobile trucks that are not properly called trailers are taxable as a part of the truck.

Where a manufacturer sells automobile accessories or parts to a jobber who in turn sells them to a manufacturer of completed cars the tax is paid by the manufacturer who sells these parts or accessories to the jobber. Where a manufacturer sells raw materials to an accessories maker who in turn sells the accessories to a manufacturer of completed passenger cars, the producer of the completed vehicles pays a tax on his sales and no tax is due on the previous sales.

When a manufacturer sells a passenger car, for example, both at wholesale and retail, he pays a tax on the passenger car sold at retail computed on the same price for which he sells them at wholesale.

Taxes are returnable and payable monthly and every return must be made under oath and in duplicate if it exceeds $10. A tax does not apply to the sale of a motor vehicle which is shipped directly to a foreign country by the manufacturer himself or sold by him for export and in proper time exported by the purchaser. If, however, an article sold for export is not exported within six months it becomes taxable. It is necessary for a manufacturer to secure a written certificate to the effect that a car or motorcycle sold is to be exported. Proof of exportation comprises an affidavit containing the name and address of the manufacturer and of the exporter, the dates of the sale and shipment and export of the car or motorcycle, the price paid and a statement that the commodity has not been subjected to further manufacture following its purchase, the name of port of export, the name of carrier issuing the export bill of lading and a copy of the export bill of lading.

Following are the complete regulations as they apply to the automotive industry:

EXCISE TAXES ON SALE BY THE MANUFACTURER

Article 1. **Effective date**—The tax is imposed on all articles sold or leased by the manufacturer, producer, or importer on or after Feb. 25, 1919, even though manufactured, produced, or imported before that date.

Art. 2. **Use of terms**—In these regulations, for convenience, unless obviously inapplicable, the term "manufacturer" is used to include also "producer" and "importer;" the term "sale" or "sold" to include "lease" or "leased;" the term "purchaser" to include "lessee," and the term "vendor" to include "lessor." The term "person" is used to include partnerships, corporations, and associations, as well as individuals.

Art. 3. **Basis of tax**—The tax is on the sale by the manufacturer of the taxable article. It is measured by the price for which the article is sold. It is on the actual sales price of the goods sold, and not on the list price, where that differs from the sales price. If the price of a taxable article is increased to cover the tax, the tax is on such increased price. Where, however, the tax is billed as a separate item such amount need not be included in the price of the article in computing the tax. The tax is payable in respect to a sale made, whether or not the

purchase price is actually collected. (See further Art. 6.)

Art. 4. **Discounts and expenses**—A discount for cash or other discount made subsequently to the sale cannot be deducted in computing the price for the purpose of the tax. Where, however, articles are sold over a period of time under an agreement for a quantity rebate, the tax, if originally computed on the gross price, may be adjusted in the return for the month in which the price is finally determined. Commissions to agents and other expenses of sale are not deductible from the price. If articles are sold at the factory or f. o. b. cars at the place of manufacture, and the delivery charges from such place to the point of delivery are paid by the purchaser as a specific item, or if they are sold delivered at a sum less delivery charges to be paid by the purchaser, such charges need not be included as a part of the price of the goods, but if the manufacturer sells goods at a delivered price and he himself pays the delivery charges, he is not entitled to make any deduction on account of the inclusion in the price of such charges.

Art. 5. **Exchanges**—If articles sold are returned and the sale entirely rescinded, no tax is payable, and if paid it may be credited against the tax included in a subsequent monthly return. See Article 41. If a part only of the articles sold at one time is returned, and credit or rebate allowed by the vendor therefor, the portion of the tax to be credited will be only the proportion of the total tax paid which the amount allowed as a credit or rebate bears to the total sales price of all the articles. If an article is sold under a guarantee as to its quality or service and is thereafter returned and a rebate made pursuant to the guarantee, the vendor may claim as a credit against the tax included in a subsequent return such portion of the tax originally paid in respect of the article as is proportionate to the amount of the price refunded. If an article is sold and thereafter, before use, exchanged for another article of a higher price, the purchaser paying the difference, the vendor should pay the tax on the second sale, but may take as a credit against such tax such part of the tax paid on the returned article, which the amount allowed as a credit for the return of such article on the second sale bears to the amount of the purchase price in the case of the first sale.

Art. 6. **Credit for taxes already paid**—A manufacturer may take as a credit against the tax imposed on him in respect to the sale of any article taxable under Section 900 an amount equal to any tax imposed under Section 900 which he has reimbursed to the vendor from whom he purchased any article forming a component part (whether or not changed in form by process of manufacture) of the article sold by him and in respect to which tax is paid by him. No credit is allowable, however, for any tax so reimbursed by a manufacturer to the vendor in respect to any article, unless such article forms a component part of an article sold by such manufacturer and in respect to which a tax is payable by him. This credit will be allowed only if the taxpayer keeps such records and evidence as will clearly establish his right to the exemption. In cases of doubt, in order to avoid penalty for default if the claim is not established, the tax should be paid in full and application made for refund.

Art. 7. **Who is a manufacturer?**—(a) A manufacturer is a person who prepares a taxable article in marketable form. There are several cases, however, in which under Section 900 there may be several manufacturers, each of whom must pay a tax, as, for example, the tax upon "articles made of fur." In such case the tax may attach on successive sales, if there are several stages of manufacture. See, however, Article 6 as to credits in such cases.

(c) A person who is employed to make an article and receives for it the cost of materials and labor, plus a specified profit, shall be considered a manufacturing agent, and the person who procures the preparation of the article for purposes of resale will be considered the manufacturer.

Art. 8. **Tax payable by the manufacturer**—The tax is to be paid by the manufacturer on all sales made directly by him or through an agent. If the manufacturer has a sales agent or sales agency to whom he only nominally sells an article, but retains an interest in the profits from the resale of the article, the taxable sale is that made by the sales agent or sales agency. On articles manufactured for a jobber by a foreign manufacturer, the jobber must pay the tax as the importer. A receiver or trustee in bankruptcy of a manufacturer conducting a business under court order is liable to the tax upon articles sold by him. Where a manufacturer consigns articles to a retailer, retaining ownership in them until they are disposed of by the retailer, the manufacturer must pay the tax based upon the price for which sold by the retailer. See Article 34.

Art. 9. **When tax attaches**—The tax attaches when the article is sold; that is to say, when the title to it passes from the vendor to the purchaser pursuant to a previous contract of sale or upon a sale without previous contract. When title passes is a question of fact dependent upon the intention of the parties as gathered from the contract of sale and the attendant circumstances. Where goods are segregated from other goods owned by the vendor and it is the intention of both the vendor and the purchaser at the time the goods are segregated that they shall then belong to the purchaser, the title will be presumed to pass at such time. In the absence of an intention to the contrary the title is presumed to pass upon delivery of the article to the purchaser or to a carrier for the purchaser. In the case of a conditional sale, where the title is reserved in the vendor until payment of the purchase price in full, the tax attaches (a) upon such payment, or (b) when title passes if before completion of the payments, or (c) when, before completion of the payments the dealer disposes of the sale by charging off, by any method of accounting he may adopt, the unpaid portion of the contract price.

Art. 10. **Sales to the Government or a State**—The tax applies to articles enumerated in Section 900 when sold to the Government. Where, however, the Government supplies a manufacturer with all materials and parts except a small portion furnished by the manufacturer, under a contract stipulating that the manufacturer shall be guaranteed a certain profit, no tax is payable, because the manufacturer does not sell the articles. Articles manufactured in plants taken over and operated by the Government are not subject to the tax. Articles sold to a State or a political subdivision thereof by the manufacturer for use in carrying on its governmental operations are not subject to the tax. Articles sold by the manufacturer to a State, county, or municipal institution are also exempt from tax when paid for entirely out of public money.

Art. 11. **Automobiles: Scope of tax**—An automobile (as well as an automobile truck or automobile wagon) is a self-propelling vehicle designed primarily for the transportation in or upon it of persons or property. Motor-driven machines for pulling a vehicle around factories and railway stations and motor-driven machine gun carriages are not taxable. An automobile hearse and a pallbearers' coach are taxable under subdivision 2. A self-propelled fire engine, at least if designed to carry only such persons as are necessary to drive it, is not taxable. If, however, it is especially designed to carry firemen not employed in or about the driving of the machine, it is taxable as an automobile. Automobile trucks equipped as hook and ladder trucks, and hose carts for the use of firemen, are likewise taxable. A usable substantially completed automobile or automobile truck produced by assembling new parts of trucks or cars is subject to tax, but a rebuilt car is not subject to tax as such, although the new parts thereof are subject to tax when sold by the manufacturer, even though assembled into a car. Automobiles which have been sold by the manufacturer are not taxable when sold again. Where, however, a manufacturer sells again an automobile which he has once sold and which has been returned to him and the first sale rescinded, the tax attaches on the second sale. A tractor is not taxable.

Art. 12. **Automobile trucks and automobile wagons**—The tax is 3 per cent of the price for which automobile trucks and automobile wagons are sold by the manufacturer. An automobile truck or automobile wagon is a self-propelling vehicle primarily designed or adapted for the transportation of property. The act specifically exempts tractors; even if sold in combination with a trailer. Any tires, inner tubes, parts or accessories for automobile trucks and automobile wagons sold on or in connection therewith or with the sale thereof are taxable at 3 per cent. Such tires, inner tubes, parts and accessories, however, as (although sold on or in connection with an automobile truck or automobile wagon or with the sale thereof) are in excess of the quantities usually sold in the ordinary course of trade to a single customer at the time of the purchase of an automobile truck or wagon, will not be taxable at 3 per cent, but will be taxable under subdivision (3) of section 900 at the rate of 5 per cent.

Art. 13. **Other automobiles and motorcycles**—The tax is 5 per cent of the price for which such articles are sold by the manufacturer. It applies to all automobiles primarily designed for carrying persons, including passenger cars, taxicabs, auto-buses, sight-seeing cars and also to all motorcycles, including side cars. Where an automobile chassis, although of such construction as is ordinarily used in automobile trucks, is fitted with a body designed for the carriage of persons, or for the carriage of persons and property, the completed whole is taxable at 5 per cent of the price for which sold by the manufacturer, and not under subdivision (1) at 3 per cent. Tires, tubes, parts and accessories for motorcycles or automobiles other than automobile trucks or automobile wagons sold on or in connection therewith or with the sale thereof are taxable at 5 per cent.

Art. 14. **Tires, inner tubes, parts and accessories sold to manufacturer**—Subdivision (3) of section 900 of the act provides that tires, inner tubes, parts or accessories shall be exempt from the tax if sold to a manufacturer or producer of automobile trucks, automobile wagons, other automobiles or motorcycles. To come within this exemption the sale must be to such a manufacturer for use by him in the manufacture or production of new cars or for free replacement under contract or guaranty. If sold to such a manufacturer for any other purpose, such as resale to a dealer or for the rebuilding of used cars, the sale is taxable. In order for the sale to come within the exemption of the statute, the manufacturer must at the time the goods are shipped or sold (whichever is prior) have in his possession an order or contract of sale, with certificate of the purchaser in writing printed thereon or permanently attached thereto, showing that the tires, inner tubes, parts, or accessories so purchased are to be used in the manufacture or production of new cars or for free replacement under contract or guaranty. If in any case such an order and certificate cannot be produced on demand of any authorized agent of the department the tax in respect to the sale will be considered in default.

Art. 15. **Definition of parts**—A "part" for an automobile truck, automobile wagon, other automobile, or motorcycle is any article designed or manufactured for the special purpose of being used as or to replace a component part of any such vehicle, and which by reason of some peculiar characteristic is not such a commercial commodity as would ordinarily be sold for general use, and which is primarily adaptable only for use as a component part of such vehicle. Mere stock or commercial commodities such as bolts, nuts, washers, screws, though used as components for such vehicles, are not "parts" within the meaning of subsection (3) of Section 900. Articles, however, which ordinarily would be classed as commercial commodities become parts when, because of their design or construction, they are primarily adaptable for use as component parts of such vehicles. Component parts of articles taxable under this definition are taxable when sold separately, if they have reached such stage of manufacture that they are primarily adaptable for use as such a component part. Thus plates, jars, and separators for automobile storage batteries are taxable when sold separately. A chassis is a part of an automobile and taxable at the rate of 5 per cent when sold separately regardless of whether it is a chassis for an automobile truck or wagon, or for any other kind of automobile. An automobile body is also a part of an automobile.

Art. 16. **Definition of accessories**—An "accessory" for an automobile truck, automobile wagon, other automobile, or motorcycle is any article designed to be attached to or used in connection with such vehicle to add to its utility, and which is primarily adaptable for use in connection with such vehicle, whether or not essential to its operation. The term "accessories" includes, for example, horns, speedometers, self-starters, spot-lights, shock absorbers, tire pumps, pressure gauges, and hydrometers. All such articles primarily adapted for use in connection with an automobile are subject to the tax even though they may sometimes be used otherwise, as for example, with motor boats. If any doubt, reasonable and bona fide, exists as to the special adaptability of an article the fact of its sale by the manufacturer to be used with an automobile or to an automobile accessories dealer will determine its taxability. A wrench or other tool of a kind sold in hardware stores for general purposes is not subject to the tax, but a wrench or other tool of special design or construction primarily adapted to be used in connection with automobiles will be subject to the tax. Robes, goggles, and lunch kits are not subject to the tax. Automobile trailers, regardless of the number of wheels

which they may have, are not parts of or accessories for automobiles; but rear portions of automobile trucks, automobile wagons, or other automobiles, not properly called trailers, are taxable as a part of the automobile. Where a manufacturer sells automobile accessories or parts to a jobber who in turn sells them to a manufacturer of completed cars the tax upon the accessories or parts is payable by the manufacturer who sells them to the jobber. Where a manufacturer sells material to an accessories manufacturer who in turn sells the accessories constructed from them to a manufacturer of completed automobile trucks, automobile wagons, other automobiles, or motorcycles, except tractors, the manufacturer of the completed vehicle is liable for the tax upon his sales and no tax is due upon such previous sales.

Art. 34. **Manufacturer also retailer**—By "customarily sells" is meant a bona fide practice of selling the same article at both wholesale and retail, in substantial quantities, and not mere occasional sales at wholesale, with the bulk of the business done at retail. Only a manufacturer who does both a wholesale and retail business and holds himself out as a wholesaler as well as a retailer with respect to the goods sold will be entitled to compute the tax upon goods sold at retail on the price for which like articles are sold by him at wholesale. As to articles sold at *wholesale*, the tax paid must be based on the actual selling price of each article sold. As to sales at *retail*, the tax on each such sale made during any calendar month must be based on the average wholesale price of all sales of like articles made at wholesale during the previous calendar month. This average wholesale price is to be obtained by dividing the sum of the actual selling prices of all such articles sold at wholesale during such previous calendar month by the total number of such articles so sold.

Art. 35. **Repeal of former taxes**—The present taxes supersede the excise taxes imposed by the Revenue Act of 1917 upon the sale of automobiles, musical instruments, sporting goods, chewing gum, cameras, toilet soaps and similar articles. The Revenue Act of 1917 remains in force for the assessment and collection of all taxes which have accrued thereunder, and for the imposition and collection of all penalties or forfeitures which have accrued and may accrue in relation to any such taxes. In the case of any tax imposed by the Revenue Act of 1917, if there is a tax imposed by the present statute in lieu thereof, the provision imposing such tax remains in force until the corresponding tax under the present statute takes effect. See Section 1400 of the statute.

Art. 36 **Colorable sales**—If a manufacturer, through the device of a selling branch or in any other manner, contrives to sell under the market price, with the result of benefiting his business or with the intent to cause such benefit, the tax shall be based on the fair market value of the articles and not on their nominal selling price. See Article 8.

Art. 37. **Return and payment of tax**—Each manufacturer of any of the articles hereinabove enumerated must make monthly returns under oath in duplicate and pay the taxes imposed on such articles to the collector of internal revenue for the district in which his principal place of business is located. Any return may, if the amount of the tax covered thereby is not in excess of $10, be signed or acknowledged before two witnesses instead of under oath. The returns shall be made on form 728 (revised). Instructions for preparing will be found on the back of the form. The returns are to be rendered and the tax paid on or before the last day of each month covering all the transactions of the preceding month, the first return to cover all transactions after Feb. 24, 1919, and before April 1, 1919. Branch houses should in general make reports to the parent house, which is liable to make monthly returns of the sales of the branch house. An itinerant manufacturer should make return and pay the tax to the collector of the district where the sales were made. The books of every person liable to the tax shall be open at all times for inspection by examining internal revenue officers. As to penalties, see Article 40.

Art. 38. **Trade with possessions of United States**—A sale which results in the shipment of articles into the United States from the Virgin Islands is taxable to the same extent as a sale of articles within the United States. Articles going into the Virgin Islands from the United States are free from tax in the United States. The same rules apply to trade with Porto Rico and the Philippine Islands. See Section 1000 of the Revenue Act of 1917 and Section 5 of the Act of Aug. 4, 1909, as amended by Section 4, subdivision C, of the Act of Oct. 3, 1913. The tax attaches, however, to articles shipped to other possessions of the United States, including the Canal Zone.

Art. 39. **Aids to collection of tax**—In collecting the excise taxes the Commissioner has the benefit of all existing internal revenue laws. In aid of the enforcement of the statute the Commissioner may require any person to keep specified records, to render returns and statements as directed to submit himself and his books to examination, and to comply with such regulations as may be prescribed.

Art. 40. **Penalties**—Any person, including an officer or employee of a corporation and a member or employee of a partnership in the course of his duty, who fails to pay or collect a tax or to make a return, is liable to a penalty of $1,000. If his failure is willful, or he otherwise tries to evade the tax, he is guilty of a misdemeanor and liable to a fine of $10,000 and imprisonment for a year. If his failure is willful, he is also liable to the addition to the tax of a 25 per cent penalty for failure to make a return and a 50 per cent penalty for a fraudulent return.

Art. 41. **Credits and refunds**—If a manufacturer overpays the tax due with one monthly return, he may take credit for the overpayment against the tax due with a succeeding return. If under Section 1312 of the statute or otherwise he similarly overcollects the tax, he shall refund the overcollection to the purchaser from him. If in a case under Section 1312 he sells on credit, other than on conditional sale, he shall return the tax at the time of the sale, but may defer collection of it from the purchaser. See Articles 44-46. For the procedure with reference to claims for refund see Sections 3220 and 3225 of the Revised Statutes, as amended by Section 1316 of the Revenue Act of 1918 and Regulations No. 14 (revised).

Art. 42. **Exemption of export sale**—The tax does not attach to the sale of an article which is either (1) shipped direct to a foreign destination by the manufacturer himself, or (2) both (a) sold by him for export and (b) in due course so exported by the purchaser. Where a manufacturer at the time an article is sold or shipped (whichever is prior) has in his possession an order or contract of sale showing in writing (1) that the manufacturer is to export the article, or (2) that the purchaser is buying the article in order to export it prior to its being used or subjected to further manufacture, there is a presumption that the sale of the article is exempt from tax, as an export sale, and the manufacturer may, for a period of six months from the date of sale or shipment (whichever is prior), rely on such presumption. This temporary presumption becomes a permanent presumption upon the manufacturer's receiving, and attaching to such order or contract, before the termination of such period of six months, due "proof of exportation" (see Article 43) of such article. On the other hand, if, within such period of six months, the manufacturer has not received, and attached to such order or contract, such "proof of exportation," then the temporary presumption that such sale is an export sale disappears, and the manufacturer shall include a tax on the sale of such article in his return for the month in which such period of six months expires. The order or contract of sale and the "proof of exportation" must be preserved by the manufacturer in such a way as to be readily accessible for inspection by internal revenue officers. No sale shall be considered to be exempt from tax under Section 1310 (c) of the act, unless its character as an export sale has been established in accordance with the above provisions.

Art. 43. **Proof of exportation**—By the term "proof of exportation" is meant: (1) An affidavit containing the following information: The name and address of the manufacturer, the name and address of the exporter (who, if not the manufacturer, must be a person who has purchased direct from the manufacturer), the respective dates of the sale or shipment (whichever is prior), and exportation of the article, the price for which purchased, the fact that the article has been exported by the manufacturer or original purchaser without having been used or subjected to further manufacture, the name of the port of foreign destination, the name and address of the carrier issuing the export bill of lading, and any further information necessary to identify the article sold with the article exported; and (2) attached to such affidavit a copy of the export bill of lading, or a certificate by the agent or representative of the export carrier showing the exportation of the article, or, if exported by parcels post, a copy of the certificate of mailing.

Art. 44. **Contract of sale before May 9, 1917**—If before May 9, 1917, A, a manufacturer, made with B, a wholesaler, a contract of sale which does not permit the addition of the tax to the amount payable under the contract, then the liability for the tax is on B, with the duty on A only to collect and pay it to the collector as provided in Article 47. If B also made before May 9, 1917, a contract of the character described with C, a retailer, the liability for the tax thus imposed on B is transferred from B to C, B being obliged only to collect the tax from C and to pay it over to A for payment to the collector. If, however, any person before May 9, 1917, made a contract of the character described with any person other than a dealer as defined in Article 48, no tax is payable in respect of the sale by him, since on May 9, 1917, no tax was in force on the sale of any of the articles described in these regulations.

Art. 45. **Contract of sale before Sept. 3, 1918, of article not then taxable**—If before Sept. 3, 1918, A, a manufacturer of candy or other article not taxable under the Revenue Act of 1917, made with B, a wholesaler, a contract which does not permit the addition of the tax to the amount payable under the contract, then the liability for the tax is on B, with the duty on A only to collect and pay it to the collector as provided in Article 47. If B also made before Sept. 3, 1918, a contract of the character described with C, a retailer, the liability for the tax thus imposed on B is transferred from B to C, B being obliged only to collect the tax from C and to pay it over to A for payment to the collector. If, however, any person before Sept. 3, 1918, made a contract of the character described for the sale of candy with any person other than a dealer as defined in Article 48, no tax is payable in respect of such sale by him.

Art. 46. **Contract of sale before Sept. 3, 1918, of article then taxable**—If before Sept. 3, 1918, A, a manufacturer of chewing gum or other article taxable under the Revenue Act of 1917, made with B, a wholesaler, a contract which does not permit the addition to the amount payable under the contract of the difference between the present tax and the corresponding tax imposed by the Revenue Act of 1917, then B is liable for such difference. A must collect and pay to the collector as provided in Article 47 the portion of the tax for which B is so liable, and he must also include in his return and pay the portion of the tax for which B is not so liable. If B also made before Sept. 3, 1918, a contract of the character described with C, a retailer, the liability for the tax thus imposed on B is transferred from B to C, who is liable for the difference between the tax imposed by the present statute and the tax imposed by the Revenue Act of 1917. B must collect and pay over to A for payment to the collector the portion of the tax for which C is so liable. For example, if any person made before Sept. 3, 1918, a contract of the character described for the sale of chewing gum with any person other than a dealer as defined in Article 48, the tax to be collected under the present statute will be the tax in force on Sept. 3, 1918; that is, the tax under the Revenue Act of 1917.

Art. 47. **Return of tax**—Each person receiving any payments referred to in Section 1312 of the statute shall collect the amount of the tax, if any, imposed by such section from the person making such payments, and shall make monthly returns under oath in duplicate and pay the taxes so collected to the collector of the district in which his principal office or place of business is located. Any person making a refund of any payment upon which the tax is so collected may repay therewith the amount of the tax collected on such payment; and the amount so repaid may be credited against amounts included in any subsequent monthly return. The return shall be made on Form 728 (revised) on or before the last day of the month following the month in which the sale is made, as provided in Article 37. The tax shall without assessment by the Commissioner or notice from the collector be due and payable to the collector at the time fixed for filing the return. If the tax is not paid when due, there shall be added as a part of the tax a penalty of 5 per cent, together with interest at the rate of 1 per cent for each full month from the time when the tax became due.

Art. 48. **Meaning of "dealer"**—The term "dealer" includes not only dealers in the ordinary sense—that is, persons engaged in the business of selling articles—but also a person who purchases an article with the intention of using it in the manufacture or production of any article intended for sale. The term does not include a person buying an article for his personal consumption or use. The United States, a State, Territory, or a political subdivision thereof, or a foreign government, purchasing an article for its own use is not a dealer.

Art. 50. **Payment of tax by uncertified check**—Collectors may accept uncertified checks in payment of excise taxes, provided such checks are collectible at par; that is, for their full amount, without any deduction for exchange or other charges. The collector will stamp on the face of each check before deposit the words "This check is in payment of an obligation to the United States and must be paid at par. No protest," with his name and title. The day on which the collector receives the check will be considered the date of payment so far as the taxpayer is concerned, unless the check is returned dishonored. If one check is remitted to cover two or more persons' taxes, the remittance must be accompanied by a letter of transmittal stating (a) the name of the drawer of the check; (b) the amount of the check; (c) the amount of any cash, money order, or other instrument included in the same remittance; (d) the name of each person whose tax is to be paid by the remittance; (e) the amount of the payment on account of each person; and (f) the kind of tax paid.

Art. 51. **Procedure with respect to dishonored checks**—If the bank on which any such check is drawn should refuse to pay it at par, the check should be returned through the depositary bank and be treated in the same manner as a bad check. All expenses incident to the attempt to collect such a check and the return of it through the depositary bank must be paid by the drawer of the check to the bank on which it is drawn, since no deduction can be made from amounts received in payment of taxes. See Section 3210 of the Revised Statutes. If any taxpayer whose check has been returned uncollected by the depositary bank should fail at once to make the check good, the collector should proceed to collect the tax as though no check had been given. A taxpayer who tenders a certified check in payment for taxes is also not released from his obligation until the check has been paid. See Chapter 191 of the Act of March 2, 1911.

Art. 52. **Misrepresentation of tax**—If a manufacturer or other vendor misrepresents the tax, he is guilty of a misdemeanor and is liable to a fine of $1,000 and to imprisonment for a year. This provision is designed, among other things, to prevent a vendor adding more than the amount of the tax to the price of an article and representing that the increase is due to the tax.

—

(*Continued from page* 1030)

The company learned that on Saturday night the union instructed its members to quit at 3.30 o'clock Monday. On Sunday the company posted notices on all bulletin boards in the plant outlining the situation, and stating that men who left at the end of 8 hours did so against the rules of the company and were no longer in the company's employ. When the men quit, their cards were immediately pulled, and steps taken to replace them with other men.

"It may take a few days and it may take two or three weeks to settle this affair, but we are going to settle it to the perfect satisfaction of all concerned," said Mr. Earl.

—

Rolls Royce to Manufacture in America

NEW YORK, May 7—Rolls Royce, Ltd., London, England, is preparing to manufacture in America. No definite location has yet been named, but it is understood that the plant will be somewhere in the eastern part of the United States, where Rolls Royce cars will be manufactured complete.

—

Johns-Manville Denver Office in New Quarters

NEW YORK, May 6—The Denver office of the H. W. Johns-Manville Co. moved from the Denver Gas & Electric Bldg. to the Iron Bldg., 1021 17th Street. Louis H. Inglee remains as manager of this branch.

20,000 Army Trucks For Roads

Part of Surplus Stock of 31,000—None Left for Sale to Makers or Public

WASHINGTON, May 8—Twenty thousand motor trucks are being turned over to the Bureau of Public Roads, Department of Agriculture, by the War Department to be distributed to the various states for use on road construction. These trucks are part of the 31,000 which were recently declared surplus by the War Department, and this disposition of them actually insures that there will be no trucks available for sale to the public or for resale to the manufacturers. The Post Office Department has requisitioned 7000, and it is expected that other Government bureaus will absorb the remaining 4000.

The trucks turned over to the Department of Agriculture are valued at $45,000,000, and include 11,000 new and 9000 used vehicles ranging from 2- to 5-ton capacity, all in serviceable condition.

The trucks are turned over under provisions of the Post Office Appropriation Bill, which authorizes requisition of surplus trucks from the army by the different Government departments. They must be used by the states on road construction under the Federal Road Aid Act. The only charges which the states will pay will be for loading and freight. The trucks will be apportioned to states only upon request of the State Highway Department on the basis of the requests received and in proportion to the financial apportionment under the Federal Road Act.

—

Will Retain Standard Vehicles

WASHINGTON, May 7—The standard types of trucks and passenger cars purchased for the army during the war will be used to replace all of the non-standard vehicles at the various army camps and posts in this country and the non-standard vehicles will be disposed of. They will be turned over to various Government bureaus, and if not entirely absorbed by them the manufacturers will be given the opportunity to buy them back from the Government. Arrangements for these plans are being completed. The standard vehicles include the B 3-ton. A 1½-ton and AA ¾ to 1-ton trucks, the four wheel drive and the passenger car standards are the Cadillac, Dodge and Ford.

—

Willys Export Corp. Formed

NEW YORK, May 6—The John N. Willys Export Corp. has been formed to absorb the export department of Willys-Overland. Inc. It has opened offices in the City Investing Building, 165 Broadway, and will direct export sales for a number of Overland interests, chiefly the Willys-Knight and Overland cars. Associated with Mr. Willys are E. C. Morse as vice-president and general manager, and John Macfadyean, vice-president in charge of sales.

Mr. Morse at the present time is in Europe, where he has been since the beginning of February studying the foreign markets. He is expected to return the end of this month.

Mr. Morse's first connection with the automobile industry was as commercial manager of the E. R. Thomas Co., Buffalo, which marketed the output of the E. R. Thomas-Detroit Co. Upon the organization of the Hudson Motor Co. he was made sales manager. In 1916 he resigned to become vice-president of the Chalmers Motor Co., of which he was also general manager. Nearly two years ago he joined the Willys-Overland interests and represented the company in Washington during the war.

Mr. Macfadyean was with the Goodyear Tire & Rubber Co. from 1909. He was first branch manager, then district manager and finally manager of the export department. He was also vice-president of the Goodyear Tire & Rubber Co. of South America.

—

New Industries in Saginaw Complicate Housing Question

SAGINAW, May 6—The housing situation in Saginaw is acute, and the business interests of the city, through the Chamber of Commerce, are exerting every influence to get people to build. The banks are aiding in this campaign. The housing situation here is attributed solely to the surprising number of new industries that have come to the city in the last two years, calling in thousands of people. Hundreds of homes are now in the course of construction.

—

Smith Leaves Buda for Midwest

INDIANAPOLIS, May 7—Lon R. Smith has resigned as sales manager of the Buda Co., Harvey, Ill., effective June 1, to become general sales and advertising manager of the Midwest Engine Co., Indianapolis. The Midwest Engine Co. was formed last year to take over the Lyons-Atlas Co. and the Hill Pump Co. It is capitalized at $3,500,000 and will produce oil engines and centrifugal and reciprocating pumps.

—

Mechanical Engineers to Meet at Detroit

NEW YORK, May 7—The spring meeting of the American Society of Mechanical Engineers will be held at the Hotel Statler, Detroit, June 16 to 19. On the opening day there will be a business meeting in the afternoon, followed by a general meeting at which the society's committee on aims and organization will make a preliminary report.

Papers on industrial research will be read at the morning session on June 17, which will be under the auspices of the research committee. This is to be made a leading topic of the meeting, because of the great impetus which has been given to industrial research through war conditions. The afternoon session on the 17th will be devoted to the subject of industrial relations, and there will be a

symposium by leading organizers on the factors dominant in the labor situation. On June 18 there will be a gas power session with papers on oil engines, and the closing session on June 19 will deal with powdered fuel and oil fuel.

—

Receiver for Campbell Appointed

NEW YORK, May 7—The Campbell Motor Car Co., which emerged as the result of the reorganization of the Emerson Motors Co., Kingston, N. Y., in September, 1917, has been placed in the hands of a receiver. It is stated that the action is a friendly one, brought about largely through a shortage of ready cash, and that there is a strong probability that the company will be reorganized. In the meantime the receiver is to continue the business. The action to have receivers appointed was brought by Abel L. Smith, who holds 166 1/3 shares of the company's stock. The receivers are Marcus Helfand and E. V. Wilson.

Not long after the Emerson company was reorganized into the Campbell company certain contracts were entered into with the United States Government, the Y. M. C. A. and the Overseas Corp. for the delivery of ambulances. All of these contracts were cancelled, however, before the company got into production on them. It is stated that the company is at present solvent, though President J. A. Campbell admits that debts amounting to some $60,000 are pressing.

—

Uncompleted Ordnance Contracts

WASHINGTON, May 5—Tank and tractor contracts totaling $57,469,700 have been cancelled, and all cancellation negotiations have been completed regarding them. Contracts totaled at $136,067,300 have been suspended with the suspension accepted by the contractor. Orders totaling $27,357,300 have been ordered suspended. Nine per cent of the orders outstanding for tanks and tractors valued at $72,328,000 remain to be completed.

—

Motor Contracts Outstanding

WASHINGTON, May 5—Of $419,184,000 worth of orders for motor trucks and other motor vehicles outstanding on Nov. 11, 1918, there were $18,023,000 left on order on April 1. Of the total, 67 per cent were canceled, 29 per cent delivered, leaving a balance of 4 per cent due.

—

No Motor Driven Fire Fighting Equipment Sold

WASHINGTON, May 5—Motor driven fire fighting equipment that has been purchased by the Army is not for sale, and will not be sold, according to a statement made to-day by the Director of Sales.

—

Sell Castor Oil and Castor Beans

WASHINGTON, May 5—The Bureau of Aircraft Production sold castor oil and castor beans, forming a surplus above the needs of the Air Service, valued at $332,927.89.

Industry Waiting for Steel to Drop

Expect Lower Price Through Railroad Administration—Buy Only for Immediate Needs

DETROIT, May 5—The steel situation in Detroit has not changed in the last two weeks. An open market prevails, with most companies purchasing only enough to cover immediate needs and very few contracting for the season's output. Some of the large automobile companies are covering themselves by contracts, but the majority are not. The trade is uncertain. Some purchasing agents are looking for a further drop in price below that recently fixed by the government. They argue that the Railroad Administration, which refuses to pay the price fixed by the government and the steel interests, will ultimately win out and bring the market further down.

Others declare the steel price is at rock bottom now, but are withholding their orders due to the uncertain conditions abroad. They are waiting until conditions clarify, which they hope will occur in the next few weeks. They predict that there will be no buying to speak of until the peace conference is over, a definite government reconstruction policy announced, Congress again in session, and the Railroad Administration and the steel interests settled upon a standard price.

One purchasing agent for an automobile company which will build 40,000 cars this year sums up the situation as follows:

"We are buying steel only as we need it. We are not contracting for any fixed amount. We are having no trouble in getting steel, but we expect the price will drop materially, and we are waiting for that drop before buying heavily.

"There is no question in my mind but what the price is going down. I say that because of the difference between the basic price of steel before the war and the price to-day. Prices dropped somewhat after the signing of the armistice, but there is still an increase of over 100 per cent over the price in 1914. I do not know what the increased cost of steel manufacture amounts to, but I do not think it is sufficient to merit upholding the present price.

When the government Railroad Administration and the steel interests agree upon a price of steel for the railroads, the automotive industry is going to benefit by the same reduction, regardless of the present price which has been regulated by the government. The automotive industry is nearly as great a steel consumer as the railroads. The big automobile companies have been buying in fair quantity, while the railroads, building industries and other consumers have been holding back. It is a broad statement, but I believe that the automotive industry has saved the steel companies from a stagnant market, and there is no reason why we should not benefit greatly if the Railroad Administration should succeed in getting a further price cut."

—

British Steel Manufacturers Disturbed by American Prices

LONDON, April 19—The recent cut in American prices of $4.25 for pig iron and $12 for finished steel brings the American price so far below British prices that many of England's manufacturers feel her domestic and foreign markets are both threatened. At the revised prices, 4-inch billets bring $38.50 per gross ton in America, while the British figure is $61.25. The American price for galvanized sheets is about $105 per ton, and the British $140. When the British government removes its subsidy from pig iron, the price is expected to advance at least $5. Sellers cannot quote prices for future business, and as a result business is slowing up. As Great Britain doubled her steel market capacity during the war, manufacturers would feel the loss of her market keenly. As a result import restrictions are being urged by some manufacturers to protect their market.

—

Germany May Buy Copper Soon

WASHINGTON, May 6—It is expected that Germany will be in the market for copper within the next few months. At present there is a surplus of about 2,000,000 lb. of copper. Copper producers are operating at about 50 or 60 per cent capacity, but the demand is said to be increasing and it is also expected that countries which have been cut off from supplies during the war will help reduce the surplus. The embargoes against copper still hold in France and Italy, but, it is believed, will not continue much longer. England has already removed all copper import restrictions.

—

N. Y. Amends Law to Permit Air Insurance

ALBANY, N. Y., May 6—Three bills amending the state insurance laws to permit marine, fire and casualty insurance companies to insure against loss or damage to airplanes, seaplanes, dirigibles and other aircraft have been signed by the Governor. The Governor also signed the Booth bill requiring motor trucks operating on state highways to be equipped with mirrors or some reflecting device giving drivers a view of the road in the rear.

—

Maxim Drops Maxim Silencer

MILWAUKEE, May 2—The Geuder, Paeschke & Frey Co. is now manufacturing the Maxim silencer formerly manufactured by the Maxim Munitions Corp.

—

Dort Producing 100 Daily

FLINT, May 1—The Dort Motor Car Co. is running more cars daily than ever before since it was organized. Daily production is hitting the hundred car mark. The entire production for the

months of May and June is already contracted for.

Hereafter the Earl C. Anthony Co., Inc., will handle Dort distribution on the Pacific coast. This company succeeds the Frawly Motor Car Co. of San Francisco as coast distributers, and the Leach Motor Car Co. of Fresno as distributers. The Anthony company's headquarters are in Los Angeles, but the firm maintains seven branches throughout the state, being represented in San Francisco, San Diego, Fresno, Stockton, Sacramento, Oakland and San Jose.

Briscoe Carbureters to be Made in Pontiac

PONTIAC, MICH., May 3—The Briscoe Carbureter Co. of Jackson is about to move to this city. Frank Briscoe, former automobile manufacturer, is at the head of this company which is now producing carbureters on a small scale. Ground has been broken here for the new plant. It will be a 1-story concrete structure, 60 x 200 ft. The plant is to be completed and the company in production within the next 70 days. About 40 men and women will be employed at first. The Briscoe carbureter is designed principally for use on Ford cars.

Mitchell Plans for 100 a Day

RACINE, May 2—The Mitchell Motors Co. completed its government four-wheel drive truck contract last week, and is now returning to commercial production as quickly as possible. It is expected that the plant will reach a production of 100 cars a day within the next month.

Capacity for 500 Studebakers a Day

SOUTH BEND, May 2—The Studebaker Corp. will have capacity for 500 cars per day when the extensive additions now building here are completed. These will include a group of buildings to occupy 61 acres and give from 3,000,000 to 4,000,000 sq. ft. of floor space: 12,000 persons will be employed. This is all in addition to the present Studebaker plant.

Wallis Tractor Production Doubled

RACINE, May 2—Production of the Wallis tractor is to be more than doubled within the next month. The factory has been partly closed for the installation of new equipment and a progressive assembly system. It is estimated that the plant will be in complete production by June 1, increasing from its present rate of 10 to 24 tractors per day.

Melling Resuming Operations

LANSING, MICH., May 2—The Melling Forging Co., recently destroyed by fire, will shortly resume operations with two shifts. Previous to the fire the plant was in operation with three 8-hr. shifts. Repairs to the building are nearly complete.

Hudson Super-Six Reduced $225

New Models Incorporate Many Body Refinements—Color Schemes Different

DETROIT, May 5—A price reduction of $225 has been made in the 7-passenger Hudson Super-Six and the other models have been reduced on a corresponding scale. In connection with this announcement there is also the announcement of a number of refinements in detail. The springs have been modified and longer shackles used to give a flatter suspension and better riding qualities. The frame has been increasesd to 7 in. in depth and a new square cross-member has been added in front of the gasoline tank at the rear of the chassis for greater rigidity. The rear axle has also been strengthened. There is a stronger ring and pinion gear and an improved adjustment of the ring gear. The wheels have solid rims and the tire equipment is now 34 x 4½ in. on all models. The front and rear wheels have 12 spokes.

The brakes have also been enlarged, the former size of 14 x 2 in. having been increased to 15⅛ x 2½ in. There have also been a few detailed changes, such as a larger horn, the license and lamp brackets attached to the cross-tube instead of the fender and an improved ignition switch, choke control and pilot lamp.

In the body works and control units the levers have been made longer, bringing them within easier reach of the driver. Gypsy curtains have been provided on both the 4 and 7-passenger phaetons.

In the 7-passenger phaeton the comfort, appearance and strength of the auxiliary seats have been notably improved. These seats are now upholstered in long grain leather pleated over Marshall springs. The steel braces supporting the backs of these seats have been leather covered. Scuff plates now cover the entire door opening and the door locks have larger bolts. Solid brass robe rails have also been provided. The robe rail now runs the width of the back of the front seat to provide a hand rest for passengers entering the tonneau, and all of the fixtures are nickel-plated.

New painting styles are also used on the Model O Super-Six. The body and wheels of the 7-passenger phaeton are finished in Valentine blue with black fenders. The body is striped in white and the hood louvres and wheels are also painted in the same manner to bring out the lines of the car. The body of the 4-passenger phaeton is finished in the same shade of blue as the 7-passenger, but the wheels are vermilion and the striping on the body bevel and louvres sets off the 4-passenger lines.

The cabriolet and sedan are also finished in Valentine blue throughout and matched with the cloth upholstery. The coupé and touring limousine are finished in light Brewster green, deep maroon and Valentine blue, and are upholstered in harmonizing fabrics. Following are the new and old prices:

	New Price	Old Price
Seven-passenger phaeton	$1,975	$2,200
Four-passenger phaeton	2,075	2,300
Cabriolet	2,450	2,750
Sedan	2,775	3,000
Coupe	2,950	3,100
Touring limousine	3,300	3,400
Limousine	3,650	3,650

Hayes Wheel to Occupy Old Buick Plant

JACKSON, MICH., May 3—The Hayes Wheel Co. has leased the old Buick plant, which was occupied during the war by the Jackson Munition Corp. The Hayes company will use the plant for the manufacture of tractor wheels. The plant was used by the Imperial and Mutual Motors for car manufacture after it was abandoned by the Buick. The last car made there was the Marion-Handley.

Ignition Plug Co. Locates in Louisville

LOUISVILLE, May 5—The Ignition Plug Co., Dayton, has established a plant at 14th Street and Broadway and is preparing to manufacture spark plugs. The company is capitalized for $50,000, with the following officers: President, E. R. Stucky; vice-presidents, H. C. Smith and C. D. Rodman; secretary and treasurer, W. T. O'Neal; assistant secretary, A. C. Reager.

Van Dorn & Dutton Open Branches

CLEVELAND, May 5—The Van Dorn & Dutton Co. has opened branches in New York and Chicago. Harry F. Keegan will manage the Chicago office at 1241 First National Bank Bldg. His brother, John, will manage the New York office at 30 Church Street.

Huffman Bros. to Make Trucks

ELKHART, IND., May 2—Huffman Bros. Motor Co., formed recently, has secured a plant in which will be manufactured two types of medium priced trucks. One with internal final drive is listed at $1,495, and the other, with worm-gear final drive, is listed at $1,695. W. L. Huffman is president of the company, and other officers are: Vice-president, F. C. Huffman; treasurer, Leroy Huffman; secretary, Verne C. Cawley; general manager, R. S. Wiltrout; sales manager, N. L. Kuhnen.

Arrow Grip to Have New Plant

GLENS FALLS, May 3—Ground will be broken at once for the new plant of the Arrow Grip Mfg. Co., to be erected on a 4-acre plot on Dix Avenue. The company has been reorganized and new directors added. The following officers were elected at its annual meeting: President, George Tait; vice-president, William H. Denning; secretary and sales manager, E. G. Mertens; treasurer, William H. Gelshenen; assistant treasurer and general manager, T. M. Avery. The officers and George F. Underwood, C. F. Burns, and G. F. Bayle, Sr., form the

board of directors. The Arrow Grip Mfg. Co. is incorporated for $500,000, of which $300,000 capital stock has been paid in.

—

Indianapolis Entries Total 43

NEW YORK, May 5—On May 1, the closing of the entries for the Indianapolis 5-Mile Victory Sweepstakes race for May 31, 43 entries appear on the lists. There are still four drivers to be named, for a Hudson special, a Detroit special and two Premiers. Omar Toft will drive his old Miller special under the new name of Darco special. Tom Alley has entered with a Bender special, a car built by him for C. J. Bender, president of the Ahlberg Bearing Co. The car has a 4-cylinder engine, with 3⅝ in. bore and 7 in. stroke, giving a displacement of 289 cu. in.

Only 33 out of the 43 entered for the race on May 31 will be permitted to start, as a rule of the American Automobile Association limits the number of cars in any speedway race to one for every 400 ft. of track. Beginning May 27, time trials will be held on the Indianapolis speedway to eliminate ten cars. Each contestant will be permitted three trials for speed in a single circuit of the 2½-mile track, the best record standing. No entrant who cannot show a greater speed than 80 m.p.h. will be permitted to enter. Starting positions for the contest will be awarded in the order of the speed shown in the time trials.

The complete list of drivers and cars follow:

Clifford Durant	Chevrolet special
Dario Resta	Sunbeam
Jean Chassagne	Sunbeam
H. C. Simmons	Hudson special
J. M. Reynolds	Hudson special
Eddie Pullen	Hudson special
W. W. Brown	Richards special

Foreign Drivers Arrive for Races

NEW YORK, May 6—Several of the foreign drivers scheduled to take part in the 500-Mile Victory Sweepstakes speedway race at Indianapolis on May 31 are already on their way here. René Thomas and Albert Guyot, two of the Ballot team, arrived in this city yesterday on board the Savoy. Paul Bablot and Louis Wagner, the remaining members of the Ballot four, sailed from Havre on May 4 on the Espagne, which is due on May 13. Andre Boillot, who will drive a Peugeot, is also a passenger on the Espagne.

British Army Used 46,700 Motor Vehicles in France

PARIS, April 15—The British army in France made use of 46,700 motor vehicles, of which 30,000 were trucks. Despite this big mechanical fleet, the number of animals was constantly on the increase, and attained 400,000 horses and mules before the armistice was signed.

The British forces were responsible for the upkeep of 4500 miles of roadway. The traffic was of such a heavy nature that for one mile of ordinary road it was necessary to provide 100 tons of road material per fortnight for maintenance. During the month of October 85,000 tons of road material were carried weekly by motor truck, this involving a gasoline mileage of 14,000,000 weekly. The total amount of stone used for road maintenance from the beginning of 1918 to the date of the armistice was about 3,500,000 tons.

In his last official report, Sir Douglas Haig points out that mechanical appliances have not reduced the importance, in any degree, of infantry and artillery. As an instance of the interdependence of tanks and artillery it is stated that in the actions fought east of Amiens on Aug. 8, 1918, vast numbers of tanks were employed and carried out their tasks in the most brilliant manner. Yet the return of artillery munitions shows that in no action of similar dimensions had the expenditure of ammunition been so great.

While the war has given no new principles, the different mechanical appliances, particularly the rapid improvement and multiplicity of airplanes, the use of immense numbers of machine guns, the employment of vast quantities of barbed wire, the enormous expansion of artillery, and the provision of great masses of motor transport, have introduced new problems of considerable complexity concerning the effective co-operation of the different arms of the services.

—

American Police Aid French in Paris

PARIS, April 16—American military police now control automobile traffic on all the main avenues and boulevards of this city. The Americans are paired with French policemen and have authority not only over American drivers, but over French, English, Italian and other military cars, as well as over French civilians.

This scheme had to be adopted because of the international character of the automobile traffic in Paris and the growing recklessness of drivers. The Peace Conference has brought into the city more army drivers and more varied nationalities than during any period of the war. The United States is represented by the Army, the Navy, the Y. M. C. A., the Red Cross, the K. of C., Salvation Army, as well as the military cars attached to the Peace Conference. The British have big military, naval, and air services in Paris. The Italians are almost equally important, while in addition there are Belgian, Polish, Greek, Roumanian, Portuguese, Jugo-Slav and other missions, all of which have important automobile services.

—

Discontinue Flying Fields

WASHINGTON, May 5—Ten flying fields will be abandoned by the War Department as soon as the equipment in storage at these fields can be disposed of. Other departments, including Interior, Commerce, Navy, Treasury and Agriculture, have been informed that these fields will be discontinued so that they can make use of them or the equipment if they desire. Following are the ten fields to be discontinued:

Barron Field	Fort Worth, Texas
Call Field	Wichita Falls, Texas
Carruthers Field	Fort Worth, Texas
Eberts Field	Lonoke, Ark.
Love Field	Dallas, Texas
Payne Field	West Point, Texas
Rice Field	Waco, Texas
Taliaferro Field	Fort Worth, Texas
Taylor Field	Montgomery, Ala.
Gerstner Field	Lake Charles, La.

—

Uniontown Entry List Lengthens

NEW YORK, May 5—The complete list of entries for the 112-mile Uniontown race for May 17 as received so far by the Contest Board of the American Automobile Association includes:

Louis LeCocq	Roamer special
Kurt Hitke	Roamer special
Eddie Pullen	Hudson special
Cliff Durant	Chevrolet special
Harold Simmons	Hudson special
Wilbur D'Alene	Duesenberg special
Dennie Hickey	Stickel special
Ray Howard	Peugeot special
P. W. Monahan	Johnson special
Joseph Boyer	Frontenac special
Louis Chevrolet	Frontenac special
Gaston Chevrolet	Frontenac special
Eddie Hearne	Durant special

British Import Restrictions Lifted

WASHINGTON, May 2—The restrictions on the importation of certain commodities, including Edison cells (and component parts) for electrically propelled vehicles, machine tools and parts, tools, appliances and parts, including abrasive wheels, drills, drill presses, drill sleeves and sockets, emery wheel dressers, hand and breast drills, lathe carriers and lathe dogs, have been removed by Great Britain, and according to a statement of the War Trade Board may be imported freely under general license.

The War Trade Board under special license will permit the importation of solid drawn weldless tubing in very special circumstances, as well as ball bearings, roller bearings, ball retainers, ball-bearing bolts and steel balls.

—

Webster Electric Gets Addition

RACINE, WIS., May 5—The Webster Electric Co. is preparing to build a two-story addition, to be used for an extension to the power plant as well as the factory. The enlargement is due mainly to the growth of the company's tractor ignition business.

Ungar Becomes Vice-President of SKF Ball Bearings

NEW YORK, May 2—G. A. Ungar, who has been engineer and technical director of the SKF Ball Bearing Co. for several years, has resigned to become vice-president of the company, of which he has been a director since its organization.

Seward in Charge of Walden-Worcester Office

WORCESTER, MASS., May 2—Walden-Worcester, Inc., has opened a New York sales office at 295 Broadway. Howard H. Seward is in charge.

Nonnes Gets Foreign Stock of Norma Ball Bearing

NEW YORK, May 5—Walter M. Nonnes, who has been president and general manager of the Norma Ball Bearing Co. since its formation in 1911, on Saturday purchased all of the foreign controlled stock of the company at a sale of the Alien Property Custodian. A total of 1950 shares, valued at $500,000, thus becomes the property of Mr. Nonnes and his present business associates. The business will be enlarged and expanded as conditions warrant. Executive control of the business has been vested in Nonnes since the formation of the company, and there will be no changes in the administration.

Earl A. Stone, formerly manager of the Detroit branch of the Wheeler-Schebler Carburetor Co., Indianapolis, has been appointed sales manager of the company to succeed George T. Briggs, who resigned.

Fred W. Thomas has opened an office in Cleveland, Ohio, as consulting engineer. He was formerly chief engineer of the Olympian Motors Co., Pontiac, Mich.

Capt. Wakeman Hackett, recently released after 20 months in service, has become associated with the Oshkosh Motor Truck Mfg. Co., Oshkosh, Wis., as factory representative covering the Middle West.

H. H. Lotz, for many years with Lowe Bros. Co., has joined the sales force of the Hilo Varnish Corp. He will cover southern Ohio with headquarters at Dayton.

J. H. Weller, formerly assistant production manager of the Packard Motor Car Co., has been appointed assistant to B. W. Burtsell, president of the Herschell-Spillman Motor Co., North Tonawanda, N. Y., and will be in charge of production.

W. R. Mason, Albany, N. Y., has been appointed sales representative of the O. Armleder Co., Cincinnati, to cover the state of New York.

Men of the Industry

Changes in Personnel and Position

Guthrie Re-opens Engineering Office

CLEVELAND, May 2—Major James Guthrie, honorably discharged from the U. S. army, has re-opened his consulting engineering office at 420 Hickox Building, here. He served in the Ordnance Engineering Department at Washington for a year, and eight months as engineering manager of the Michigan Ordnance District.

Ferguson President of Chamber of Commerce

WASHINGTON, May 5—Homer Ferguson, president of the Newport News Shipbuilding Co., has been selected as president of the U. S. Chamber of Commerce for the coming year.

R. P. Leigh has been appointed factory manager of the Hackett Motor Car Co., Grand Rapids, whose plant has just been completed. It expects to be in production by July 1.

C. W. Jacoby has been appointed manager of the Philadelphia office and warehouse of Peter A. Frasse & Co., Inc., succeeding W. F. Moore who resigned.

May S. A. E. Meeting to Discuss Aviation

CHICAGO, May 6—The May meeting of the mid-west section of the Society of Automotive Engineers will be held at 1735 Monadnock Block, Friday, May 9, at 8 p.m. W. B. Stout, sales and aircraft manager of the United Aircraft Engineering Co., will tell of the lure of aviation, in which he will discuss present airplanes and their influence on car design, also future airplanes and engines. The second paper will be by O. E. Szekely, chief engineer and production manager of the Velie Motors Corp., on the development of kerosene burning fuel.

The meeting will be preceded by an informal dinner at 6.30 p.m. at the Chicago Engineers Club. Tickets are $1.50. Friends of members and interested engineers are invited. Reservations for the dinner can be made through Francis W. Parker, 1410 Marquette Building.

E. B. Hayes Doubling Plant

OSHKOSH, Wis., May 5—The E. B. Hayes Machinery Corp., manufacturer of worm-drive axles for trucks, has under consideration plans for new buildings which will more than double the size of the plant and provide facilities for greatly increased production. Work probably will be undertaken during May so increased production may begin late in the summer.

Howard Spohn Again with Class Journal

NEW YORK, May 5—After something over two years as commercial manager of the U. S. Ball Bearing Mfg. Co., in Chicago, Howard L. Spohn has returned to the Class Journal Co. Spohn was connected with the Class Journal Co. for the 7 years previous to his going West, and upon his return to this city he is taking up the same general duties he was performing prior to his venture in the manufacturing world.

De Kam & Petit Open Engineering Office

William H. Petit, former chief engineer of the Olympian Motors Co., Pontiac, and Major C. T. De Kam, formerly of the Canadian forces, have united under the firm name of De Kam & Petit, with offices in Detroit, and will carry on general engineering work.

George Smith Heads Dixon Crucible

JERSEY CITY, May 5—George T. Smith was elected president of the Joseph Dixon Crucible Co. at the annual meeting recently; other officers elected being, vice-presidents, George E. Long and J. H. Schermerhorn; secretary, Harry Dailey; treasurer, William Koester; assistant secretary-treasurer, Albert Norris. The Philadelphia branch has been moved from 1020 Arch Street to the Finance Building. W. G. Stringer, Philadelphia district sales representative since 1912, continues in charge.

Willys Chairman of N. A. C. C. Show Committee

NEW YORK, May 6—The National Automobile Chamber of Commerce has appointed John N. Willys chairman of its show committee for the 1920 passenger car show. Other members of the committee are H. J. Root, Westcott, and H. M. Jewett, Paige. M. L. Pulcher, Federal, heads the committee on motor truck show, his associates being A. J. Whipple, Diamond-T, and David S. Ludlum, Autocar.

Willys-Overland Stockholders to Meet

TOLEDO, May 5—The regular annual meeting of the stockholders of the Willys-Overland Co. will be held at the factory offices of the company here May 13 at 2 o'clock. Directors for the ensuing year will be elected.

National Wire Wheel President Dies

GENEVA, N. Y., May 5—Wallace W. Page, president of the National Wire Wheel Works and secretary of the Geneva Cutlery Corp., died last week of pneumonia.

William Hyslop, president of Hyslop Brothers, Toronto, Can., died at his Toronto home on April 26. The concern of which he was head is one of the largest jobbers of automotive equipment in Canada and Cadillac distributer for eastern Canada.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Ford Assembly to Be Done at Plant

DETROIT, May 3—The Ford Motor Co. will hereafter assemble its cars for Michigan at the plant instead of at the factory branch, which was sold last week to a local real-estate company for approximately $1,500,000. Plant assmbly will not take place until after Nov. 1, on which date the company turns over its 10-story branch building to new owners.

The Ford company will this fall build an assembly plant at the factory. Just across Woodward Avenue from the Ford plant, a sales and service station will also be built to handle the commercial work now being cared for at the factory branch. The company decided to discontinue assembly work at the branch when it was apparent that the cost of transporting parts from the factory to the branch by truck was becoming excessive. This work can be handled at the factory at a greatly reduced cost.

The Ford company is now running 3,000 cars daily. Approximately 300 cars a day are assembled at the factory branch for the Michigan trade. On April 8, the company completed Model T engine No. 3,000,000. The first Model T engine was cast in 1908 and has been changed but little since that time. There are now approximately 3,150,000 Ford engines in operation.

Standard Aircraft Liquidating

ELIZABETH, N. J., May 2—The Standard Aircraft Corp. is winding up its affairs preparatory to going out of business. It does not feel that commercial aircraft is getting sufficient support at this time to warrant its continuation. The parent organization commenced work in 1914 and the present company was organized in 1915 to manufacture aircraft exclusively, and was active all through the war.

Badger Aluminum Ready for Production

SHEBOYGAN, WIS., May 2—The Badger Aluminum Co., incorporated early in April with an authorized capital of $50,000, decided to double this amount, making it $100,000, at the stockholders' meeting for permanent organization. Equipment and machinery is now being installed in the new plant and the company hopes to be ready to start regular production of castings and stampings by June 15. Officers were elected as follows: President, William A. Erdmann; vice-president, Noah Saemann; secretary, William F. Toepel; treasurer, Charles Voigt; director, William Markwardt.

Marlin-Rockwell Motor Radiators Back to New Haven

NEW HAVEN, May 3—The Motor Radiator Division, formerly the Mayo Radiator Division of the Marlin-Rockwell Corp., which was located temporarily in New York for war work, will shortly be moved back to the plant here. During the war this division manufactured airplane radiators for the Government.

First Antigo Tractor for Demonstration

ANTIGO, WIS., May 2—The first demonstrating model of the new four-wheel drive tractor which the Antigo Tractor Syndicate is preparing to manufacture in quantities was completed at the shops of the Dauber-Kratsch Machine Co., Oshkosh, Wis. The design is by D. S. Stewart. Mr. Stewart assisted in the founding of the Topp-Stewart Tractor Co., Clintonville, Wis., from which he retired two and a half years ago.

His latest design weighs 3500 lb. It uses a 32 hp. Doman engine and Hayes front and rear axles. The tractor, although 136 in. long overall, turns within a 16-ft. circle.

Klumb Engine Now Liberty Tractor

SHEBOYGAN, WIS., May 3—The Klumb Engine & Machine Co., an old-established gas engine and farm machinery manufacturing concern, has been reorganized under the laws of Iowa as the Liberty Tractor Co., and is now moving its equipment and offices to Dubuque. Paul Klumb, president and manager of the Sheboygan company, will continue to be associated with the company. At Dubuque a new plant is being erected. The first structure, a machine shop, 80 x 180, is ready for occupancy. An assembling floor and gas engine shop, 60 x 300 and 100 x 250 respectively, will be built during the summer. Practically the entire output until Jan. 1 has been contracted for.

Aircraft Factory Converted for Car Manufacture

WASHINGTON, May 2—Straker & Squire, Ltd., British car manufacturers, have purchased from the Government the national aircraft engine factory at Edmonton, proposing to transfer all its manufacturing industries there, according to a report from Commercial Attaché Kennedy at London. The purchasers intend to concentrate on two standard models—a 6-cylinder passenger car and a 4-cylinder commercial chassis suitable for transport services and omnibuses.

The cars will be British-built throughout and fitted with British magnetos. The entire factory will be organized on the lines of quantity production from standard jigs, and it is anticipated that 5000 workers will be employed continuously. It is planned to produce 2000 complete vehicles in the converted factory in the first year. The price paid the Government for the factory was $681,300. The Disposal Board has 14 other national factories available for private enterprise.

Ricardo Tank Engine Developments

LONDON, April 15—Developments of the cross-head type of engine invented by Harry R. Ricardo, whose engine was used in the British tanks, is continuing along broader lines. The present development includes a 4-cylinder engine for heavy trucks, with cylinder 4¾ x 6, and a crankshaft speed of 1500 r.p.m. This engine has been developing 72 b.-hp. in tests and is a development of the tank engines in that the valve gear is entirely enclosed. Another development is a heavy duty kerosene engine for tractors intended to develop 30 b.-hp. at 800 to 900 r.p.m. Mr. Ricardo has been accomplishing results with the use of kerosene in the cross-head piston engine. He uses cooled exhaust gas in his patented carbureter and is getting a higher horsepower than with gasoline.

American Motors Corp. Increases Capital $500,000

NEW YORK, May 2—In order to increase the output of its plant at Plainfield, N. J., the American Motors Corp. has made a stock issue of $500,000. The output for May is scheduled at 150 cars, June 200, and July and thereafter, 250 per month. At the directors' meeting, P. W. Hansl was elected vice-president and supervisor of sales. He has been secretary and treasurer of the company for years. George G. Gates succeeds him as secretary. G. A. Brower, president of the Penn-American Motor Car Co., Philadelphia, was elected a director. George W. Craven continues as a director, and Laurence P. Rife, for many years production manager of the Hudson Motor Car Co., who has been factory manager since March 1, is also a director of the corporation. Robert Bursner remains president and Louis Chevrolet first vice-president.

Steel Spring Piston Ring Organized

NEW YORK, May 3—The Steel Spring Piston Ring Co. has been formed by A. J. H. Kuhsiek, formerly factory superintendent of Edward V. Hartford, Inc., and A. Meyer, formerly production manager of the same concern, to make the Bull Dog ring, a three piece ring having several novel sales points.

Derf Factory Moved

NEW YORK, May 2—The Derf Mfg. Co. has moved to new factory quarters at 9-13 Walker Street, where both equipment and number of employees have been increased. The company's office remains at 90 West Broadway.

New Chicago Office for Van Dorn Tool

CLEVELAND, May 2—The new Chicago office of the Van Dorn Electric Tool Co. has been opened at 527 South Dearborn Street and extends to 528 Plymouth. William Cottrell remains as sales manager of the Chicago branch.

New York Exports Drop During March

Cars Increase in Number, but Value Is Lower—Trucks Show Big Fall—Parts Also Show Loss

NEW YORK, May 3—Although our exports of automotive products through this port show a falling off when compared with those of February, they are well in front of January's totals. Taking the values of cars, trucks and parts for the three months, the following results are arrived at:

January	$4,274,827
February	6,870,057
March	4,677,369

It is not always a fair method of comparison to take any one month against another. This method does not necessarily indicate either a gain or a falling off in the sense that the actual shipments are limited by the tonnage available for the various ports. For this reason it should not be assumed that because our exports during March are below those of February, our foreign trade is falling off.

The shipping shortage is still severe and there are many thousands of dollars worth of automotive products awaiting overseas transportation.

Automobile, Truck and Parts Exports from New York for February

	Cars		Trucks		Parts

Enemy Trading Lists Withdrawn

WASHINGTON, May 6—All enemy trading lists issued by the War Trade Board have been withdrawn by it with the authority of the Associated Governments, at the same time all restrictions attached to trading or communication with persons in such lists have been removed. Subject to other rules of the War Trade Board, limitations of trade and communication with persons outside the United States, with whom trade was prohibited by the Trading with the Enemy Act, have also been withdrawn. This action does not, however, affect any of the restrictions against trade with Germany or Hungary, nor does it authorize trade with any person or company taken over by the Alien Property Custodian. The Associated Governments have reserved the right to re-issue the Enemy Trading List if found necessary.

Want Two-thirds Canadian Products Permitted to Enter England

WINDSOR, ONT., May 3—Automobile manufacturers of the border cities, comprising Ford, Walkerville, Sandwich, Windsor and Ojibway, favor a compromise in British tariff regulations that will permit Canadian products, provided they are 66⅔ per cent of Canadian manufacture, to enter the British Isles.

A number of Canadian car factories are subsidiaries of United States concerns, and are utilized largely for assembling purposes, although recent activities indicate that in future more actual manufacturing will be done in the Dominion.

Under present regulations United States cars and parts are not allowed in the British Isles, and well-founded rumors reaching the Border Chamber of Commerce are to the effect that British manufacturers are opposed to admitting even cars from Canada, provided less than 80 per cent construction work is done in this country.

Fords May Be Made in Tokio

DETROIT, May 3—Henry Ford may establish a car and tractor plant in Tokio, Japan, according to Baron Shimpel Goto, one of Japan's most influential men, who is here conferring with Mr. Ford. Mr. Ford is now contemplating a trip to the Far East, the Baron said. The Japanese nobleman is making a study of American manufacturing methods.

Continental Motors Dividend

Continental Motors Corp., Detroit, 1½ per cent dividend payable May 15 to stockholders of record May 10.

$6,000,000 Canadian Plant for General Motors Started

WALKERVILLE, ONT., May 5—Ground has been broken for the $6,000,000 plant of the General Motors Corp. here. Plans call for the erection of two structures, 300 x 200 ft. Within 2 weeks more than 300 men will be employed in construction work, it was stated, preference being given to returned Canadian soldiers.

Goodyear Opens Office in Spain

AKRON, May 5—The Goodyear Tire & Rubber Co. has established a branch at Madrid, Spain, with Edward M. Sonntag in charge.

Scripps-Booth Up to 45 Cars Daily

DETROIT, May 2—The Scripps-Booth Corp. will be housed in its new $1,500,000 factory this fall. While the plant is in construction production of the present plant will not be affected. The company is turning out 45 cars daily, while the demand calls for 50 per cent more than can be produced. It is exporting 150 cars monthly.

Government Disposes of 605,235 Tons Iron and Steel

WASHINGTON, May 5—The government is about to dispose of a total of 605,235 tons of iron and steel, including 47,908 net tons of raw materials, 514,460 net tons of finished steel and semi-finished products, 2,150 net tons of cast iron and steel, and 31,317 tons of scrap. The material will be disposed of on sealed bids to be accompanied by a certified check for 20 per cent of the amount of the bid, deliveries to be made f.o.b. cars.

Completing Government Aviation Engines

WASHINGTON, May 5—All orders for aviation engines for the army have been completed except those on Hispano-Suizas, and for the week ended April 17 only 1058 of these remained to be delivered. Of these 809 are the 180-hp. type and 249 are the 300-hp. type. The original order was for 6000 of the former and 500 of the latter. Deliveries of DeHaviland 4 planes are 99.9 per cent complete, 4,842 of 4,846 having been turned over.

War Department Sells Lead

WASHINGTON, May 3—Surplus stocks of lead owned by the War Department are being sold at current local market prices in the community in which the surplus is held. It is scattered throughout the country and there is no large quantity in any one place. The department has 7000 tons of lead on hand, a small percentage of the year's production, and not sufficient to affect the market.

American Welding Bureau Officers Elected

NEW YORK, May 5—At a meeting of the American Bureau of Welding at the Engineering Societies Building, by-laws were adopted and the following officers elected: Director, C. A. Adams; vice-directors, H. M. Hobart and A. S. Kinsey; treasurer, W. E. Symons; secretary, H. C. Forbes. At a directors' meeting J. H. Deppeler of the Metal & Thermit Corp., Jersey City, was elected a director of the society.

Regular meetings of the Bureau are to be held the third Friday of each month. It was also voted that a Research Committee be established to carry out the plan of co-operation in conducting investigations.

Hackett Car Plant Nearing Completion

GRAND RAPIDS, MICH., May 5—Work is nearing completion on the new plant of the Hackett Motor Car Co. This company recently moved here from Jackson.

Purchasing Agents Want Standard Invoice Forms

DETROIT, May 3—The Standardization Committee of the National Assn. of Purchasing Agents is making a thorough effort to standardize the forms used for bill heads or invoices. The members complain very strongly about the lack of standardization. They desire to have the date, invoice number and other information in some predetermined spot on the page and want the sheets of a uniform size for convenience in filing and handling.

The committee has outlined the following points, which should be borne in mind when considering this subject:

1. In order to have a standard form enthusiastically adopted by the selling organizations it should appeal to them as reasonable.
2. No attempt should be made to force anything through which will serve as a restraint upon business and therefore we should aim to make our form fit the requirements of the selling as well as the buying end of business.
3. Large selling organizations are now using accounting machinery, such as electrical tabulating equipment for statistical purposes, and any form must be large enough to permit ready use of these accounting machines without interfering with the accuracy of the work.
4. To accommodate these accounting machines it is necessary to have definite columns provided in which to show description, size, quantity, dimensions, weight, price each, total price, and a separate column for the net total of the invoice. To this must be added some other columns in many cases to suit certain lines of business, such as number of bundles, number of feet, length, etc.
5. From the standpoint of the purchasing agent particularly, and the sales department secondly, it is desirable to have the date, order number, invoice number, car number, and similar data placed in some definite spot on each and every invoice so that there is always one place to look for this information.
6. Some of the information in No. 5 should be so located on the sheet that it will be convenient when looking through a file for a definite invoice.
7. It may be necessary to provide more than one length of invoice form, but if it is possible to do so that should be avoided. One standard size would be far preferable from the standpoint of filing. This also has some advantages in the use of accounting machinery.

The subject is to be discussed at meetings of the various branch associations throughout the country. The National Assn. of Purchasing Agents has made great strides toward the standardization of catalogs, and hopes to meet with similar co-operation in eliminating the confusion which now surrounds the matter of invoices. The members of its Standardization Committee are:

W. V. C. Bulkeley, Liberty Steel Products Co., New York City.
H. H. Meehan, A. B. Dick Co., Chicago.
A. Lockwood, Lumen Bearing Co., Buffalo.
K. L. Kulow, Willard Storage Battery Co., Cleveland.
W. L. Chandler, Dodge Sales & Engineering Co., Mishawaka, Ind.

Standard Parts Dividend

Standard Parts Co., Cleveland, 1½ per cent, common, payable May 15 to stockholders of record May 6.

A Plan to Stabilize the Dollar

(*Continued from page* 1006)

authorized to mark the dollar up or down according to his own caprice? Most certainly not. A definite and simple criterion for the required adjustments is at hand—the now familiar "index number" of prices. The Bureau of Labor Statistics, which now publishes an index number, the Bureau of Standards, or other suitable Government office would be required to publish this number at certain stated intervals, say monthly. That is, each month the bureau would calculate from current market* prices how much would have to be paid for our composite basket of goods. This figure it would publish and proclaim; and this figure would then afford the needed official sanction to the Secretary of the Treasury to change the rating of the gold dollar—that is, to change the amount of gold which the mint would give or take for a gold certificate, and thus increase or diminish the purchasing power of that certificate. The certificate would always be equal to the gold dollar; and the gold dollar would be kept equal to the goods-dollar, which is the ultimate standard. If, for instance, the index number representing the current price of our composite basket of goods is found to be 1 per cent above the ideal par—that is, above the one dollar price it had at first—this fact will indicate that the purchasing power of the dollar has gone down; and this fact will be the signal and authorization for an increase of 1 per cent in the weight of the gold dollar. For what is added to the weight of the gold dollar will be automatically registered in the purchasing power of its circulating certificate.

Summary of Plan

The plan, then, as above set forth, is, in brief:

(1) To abolish gold coins and to convert our present gold certificates into "gold-dollar certificates" entitling the holder to dollars of gold bullion of such weight as may be officially declared from time to time.

(2) To retain the virtual "free coinage"—that is, deposit—of gold and the free redemption of gold-dollar certificates.

(3) To designate an ideal composite goods-dollar consisting of a representative assortment of commodities, worth a dollar at the outset, and to establish an index number for recording, at stated intervals, the market price of this composite dollar in terms of the gold dollar.

(4) To adjust the weight of the gold-bullion dollar at stated intervals, each adjustment to be proportioned to the recorded deviation of the index number from par.

(5) To impose a small "brassage" fee not to exceed any one change in the gold dollar's weight.

The crux of the plan lies in the steering rule by which the index number regulates the dollar's weight. Its significance is that to keep the gold dollar from shrinking in value we make it grow in weight, thus recognizing that a depreciated dollar is a short-weight dollar; and reversely, to keep the dollar from growing in value we make it shrink in weight, thus recognizing that an appreciated dollar is an overweight dollar.

Or again, since a heavier or lighter dollar simply means a lower or raised price of gold, we may say that to keep the level of prices of other things from rising or falling we make the price of gold itself fall or rise.

Italian Market for Automobiles

WASHINGTON, May 3—There is a great demand for a lightweight low-priced car in Italy, according to Trade Commissioner M. J. Chisea at Rome. The demand is greatest in the rural districts throughout the provinces, where the people increased their resources during the war. For instance, in Macerata with a population of 20,000, there are 500 cars in use. The car most suitable is one for general use, simple in construction, lightweight and selling at $600 to $1000 delivered.

American manufacturers of the lower priced cars would do well to survey this field and prepare for future possibilities. The market is almost a virgin one, and no particular make of car predominates. Most of the Italian cars now available are too high priced, and the majority of the people are postponing purchases until prices are lower. There is a lack at this time of standardization in the industry, which is also handicapped by the shortage of raw materials and the increasing labor costs.

As the restrictions placed by the Italian government prevent the importation of automobiles into Italy, manufacturers will necessarily have to limit their activities to organization. Publicity at this time would be advantageous, with actual demonstration a little later on. American manufacturers should be ready for this trade when importation restrictions have been lifted.

Missouri's Compensation Law

ST. LOUIS, May 3—Missouri now has a workmen's compensation law, of which some of the provisions are:

Basis of compensation—Two-thirds of the average wage; not to exceed $15, nor less than $6 a week.

Effective Nov. 1, although commissioners are to be appointed at once and immediately organize.

Employers are permitted to carry their insurance in private companies.

Employers and employees presume to be operating under the act, but they may elect whether ta come under its provisions.

Commission to be bi-partisan, and one member will represent the employers and another the employees.

Medical aid first 8 weeks will not exceed $200, employer choosing the physician, but the employee has the privilege to choose a physician at his own expense.

Temporary total disability will not exceed 400 weeks, and temporary partial disability, two thirds of the wage loss, not exceeding 200 weeks.

Pension of permanent total disability is two-thirds wages for 240 weeks and thereafter 40 per cent of wages for life.

Death burial benefit of $100 in every case: total dependents to receive two-thirds of wages for 300 weeks.

Exempts agricultural and domestic pursuits of less than five employees.

Fuel Limitations of Tractor Engines

(*Continued from page* 1003)

In nearly all so-called good oils there is a portion in the medium content which constitutes the very essence of good lubricating qualities. This constitutes about 15 per cent of lubrication oils, and it would be impossible to supply the demands if this were the only oil accepted by the user. Oil companies virtually have to fill in with lighter oils to give a flow and heavy oils to give body and viscosity at the higher temperatures.

Light oils and even medium body oils evaporate at low temperatures and are thus the cause of excessive oil consumption. Heavy oils having complex molecules break down under high temperatures. Light oils have no body or viscosity at high heat. In rough terms, therefore, the oil which comes off at medium temperatures will not evaporate excessively at high temperatures, nor disintegrate. In aviation oil, a maximum of the good medium is used. In compounding a tractor oil a little of the lighter and heavier is used with the good, and so on through the truck oils down to the oils for small passenger-car engines, where, because of the low temperatures, a maximum of the light fair quantity of the good and a minimum of the heavy can be used.

Vaporizing and atomizing defects of our present systems are our design faults affecting starting. The high boiling point of the first drop of fuel coming off at distillation tests in our gasolines is the characteristic in the modern fuels affecting starting. Because so little of the fuel can be vaporized at the intake manifold temperatures, large volumes of fuel beyond what would be necessary in an easily vaporized fuel are taken in. Motors start with difficulty at that, and all this amounts to inconvenience and bad blood between the user and modern engines.

Whatever inconvenience arises is nothing compared to the damage done to the combustion chamber with heavy fuel and the lubricating oil by dilution when the engine is cold in starting. Perhaps 70 per cent of these troubles comes from this source at the time of starting. Means for catching the heavy oil and preventing it from entering the combustion chamber must be provided.

Massachusetts Fighting Motor Legislation

BOSTON, May 3—Massachusetts motorists and dealers are up in arms over three bills that are now being threshed out by the legislature. One bill calls for tripling the fees on motor vehicles, put in by Mayor Peters of Boston. A second bill would require every motorist to be bonded before being allowed on the roads. A similar measure was killed last year and the year before. A third bill seeks to have dealers make a record every day of the cars they take in trade, and send the report to the State House to the Highway Commission and also to the local police. The used car dealers would have to hold their cars four days; the new car dealers could sell theirs by getting a permit.

Calendar

SHOWS

May 10-17—Bristol, Va.-Tenn. Cars, Trucks, Tractors, Airplanes and Accessories. Bristol Chamber of Commerce. C. W. Roberts, Manager.

May 15-June 1—Venezuela. National Exhibit of Venezuela.

June 2-6—Hot Springs, Va. Convention Automotive Equipment Assn., Homestead Hotel.

*Oct. 15—Paris. Grand Palais, International Automobile Mfrs. Congress.

Nov. 7-15—London. Olympia Motor Car Exhibition—Society of Motor Mfrs. and Trades.

December — Brussels. International Automobile Mfrs. Congress.

January—New York. International Automobile Mfrs. Congress.

February — Chicago. International Automobile Mfrs. Congress.

Feb. 23-Mar. 6 — Birmingham, Eng. British Industries Fair.

TRACTOR SHOWS

May 6-12—Sacramento, Cal. — Sectional Tractor Demonstrations, Demonstration Field.

May 30—College Park, Md. — Power cultivator Demonstration, Maryland State Dept. of Agriculture.

June 8-14—Denver, Col. Sectional Tractor Demonstrations, Denver Tractor Club.

July 14—Wichita, Kan. Automotive Committee of National Implement Assn.

Aug. 18-22—Aberdeen, S. D. Sectional Tractor Demonstrations.

October—Ottawa, Ont., Can. Interprovincial Plowing Match and Tractor Demonstration.

CONTESTS

†May 17—Uniontown, Pa., probably 112½ miles.

May 30—Atlantic City, N. J.—Airplane races—Aeronautic Convention.

May 30-31—Richmond Va.—2-Day Dirt Track Meet. Virginia State Fair Grounds Track.

May 30-31—Los Angeles, Cal.—Los Angeles-Yosemite 3rd annual gasoline economy run.

†May 31—Indianapolis, Indianapolis Motor Speedway Assn., 500 miles.

*June 14—Sheepshead Bay, L. I. Speedway race.

July 4—Atlantic City, N. J.—Airplane races—Aeronautic Convention.

*July 5—Cincinnati, O., Speedway.

*July 19—Uniontown, Pa. Speedway race.

*July 26—Sheepshead Bay, L. I. Speedway race.

*Aug. 15 — Middletown, N. Y. Dirt track event.

*Aug. 22-23—Elgin, Ill. Road race.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Sept. 27—Allentown, Pa. Dirt track event.

*Oct. 1—Cincinnati, O. Speedway race.

*Oct. 4—Trenton, N. J. Dirt track event.

*Oct. 11—Danbury, Conn. Dirt track event.

†Sanctioned.
*Tentative dates.

CONVENTIONS

May 1-June 1—Atlantic City, N. J. — Pan-American Aeronautic Convention and Exhibition—Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation.

May 21-24—Washington — Conference on Weights and Measures—Bureau of Standards.

May—Washington, Pan-American Commercial Conference, Pan-American Union Building.

June 2—Chicago, Ill.—Natl. Gas Engine Assn. Hotel Sherman.

June 23-28—Ottawa Beach, Mich.—S. A. E. Mid-summer Meeting.

Sept. 22-24 — Philadelphia. Annual Convention, National Association of Purchasing Agents, Bellevue-Stratford.

Foreign Trade Opportunities

WASHINGTON, May 3—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has inquiries for the agencies of automobiles and accessories, airplanes and airplane parts, farm tractors and trucks. Full information regarding each of the following can be had by addressing the Bureau of Foreign and Domestic Commerce at Washigton, D. C., and referring to the Foreign Trade Opportunity number.

Tunisia—Tractors of crawler type, in three sizes, 12 to 20 hp., 35 to 45 hp., and 50 to 70 hp., using gasoline or kerosene, preferably kerosene. Correspondence may be in English. No. 29235.

Colombia—Car for 20 passengers; for use in a tropical country. Plans and specifications to purchasing agent here. Name and address bureau or its district offices. No. 29237.

Brazil—An American citizen desires to purchase farm tractors. Payment, cash against documents in New York or at destination. No. 29230.

Norway—Automobiles and supplies. Terms cash against documents in New York or at destination. No. 29168.

Norway—Cars, motorcycles, tires, engines and accessories. Terms, cash against documents. No. 29185.

France—For the sale in France and Morocco of oil, low-priced cars and motorcycles. No. 29188.

Switzerland—Rubber tires and tubes, cheap cars, two and four passenger, and accessories. Purchases in large quantities. No.29190.

Egypt—Engines, motor plows, motors, lorries and agricultural machinery. No. 29034.

Spain—Gasoline or petroleum tractors from 10 to 30 hp. Four immediately. If satisfactory, ten or twelve later. Correspondence may be in English. No. 29039.

Sweden — Automobile tires. Quotations should be given f.o.b. New York. Terms cash against documents. No. 29059.

American Firm with Connection in Denmark—Trucks, cars, motorcycles, parts and accessories, marine engines, tractors, airplanes, pneumatic and solid tires and tubes, brake lining, tools and machinery for automobile shops and garages. No. 29068.

Spain—Truck tires. Quotations should be f.o.b. New York. Payment cash against documents. Correspondence in Spanish. No. 29079.

France—Low-priced cars. Correspondence in French. No. 29084.

Belgium—All kinds of electrical machinery, fittings and apparatus, internal-combustion engines, motor cars, trucks and lorries. No. 29090.

Ireland—Moderately priced light car, truck, tractor and accessories. No. 29091.

American Buying Agents for Far East—American tractors not too heavy, and fairly low, that may pass under trees on plantations, turn about in their own length, and pull from 1- to 6-disk ploy, plowing 8 in. deep. Information wanted as to the number of acres covered per 8-hr. day, gas consumption per day, etc. One light, one medium tractor, and one lightweight and one medium wheel-driven tractor. No. 29093.

Australia—Automobile accessories. Reference supplied. No. 29107.

Algeria—Lathes, drills, tools, etc., for repair work, cars, trucks and tires. Correspondence should be in French. Reference supplied. No. 29136.

Norway — Second-hand motorcycles, cars and tools. Payment through bank in New York. Reference supplied. No. 29145.

China—Rebuilt cars, motorcycles and engines. No. 20155.

Orders Placed by War Department

WASHINGTON, May 2—The War Department has approved the following orders:

McCord Mfg. Co., Detroit, radiators, $30,-739.46.

Reo Motor Co., Lansing, spare parts, $30,-867.64.

Kelly-Springfield Motor Truck Co., Springfield, O., rear parts, $34,971.20.

Standard Steel Casings Co., steel wheels, $72,688.02.

Briscoe Motor Corp, 1 set tools, 5000 differentials, $1,279.91.

Richmond Forging Co., axles, $167,538.86.

Lexington Motor Co., 1,000 10-ton trailers, $74,882.57.

Dort Motor Car Co., crating chassis, $1,738.17.

Columbia Wagon Co., escort wagons and wheels, $52,342.94.

Winona Wagon Co., escort wagons and parts, $63,146.81.

Garford Motor Truck Co., spare parts, $46,017.62.

Westfield Mfg. Co., Westfield, Mass., spare parts, $9,431.62.

Locomobile Co., Bridgeport, spare parts, $417,431.76.

Packard Motor Car Co., Detroit, spare parts, $379,888.36.

Peerless Motor Car Co., Cleveland, spare parts, $120,683.48.

Pierce-Arrow Motor Car Co., Buffalo, spare parts, $298,520.28.

The White Co., Cleveland, spare parts, $73,204.62.

Buick Motor Co., Flint, Mich., spare parts, $49,317.32; repair parts, $24,656.86.

Four Wheel Drive Auto Co., Clintonville, Wis., spare parts, $168,863.51.

General Motors Truck Co., Pontiac, spare parts, $32,193.23.

Willard Storage Battery Co., spare parts, $264,780.33.

Harley-Davidson Motor Co., Milwaukee, spare parts, $9,270.72.

Continental Motor Corp, Muskegon, Mich., repair parts, $7,358.96.

Goodyear Tire & Rubber Co., Akron, casings, $190,871.14; tubes, $6,824.30; solid pressed-on tires, $29,919.22; demountable solid tires, $10,851.50.

Firestone Tire & Rubber Co., Akron, casings, $268,017; tubes, $85,492.39.

B. F. Goodrich Rubber Co., Akron, casings, $127,647; tubes, $9,220.45.

Fisk Tire & Rubber Co., Chicopee Falls, Mass., casings, $56,991.

For Standard Tractor Ratings

CHICAGO, May 6—It is likely that a standard method of rating farm tractors may be developed by the United States Department of Agriculture, working in conjunction with the Tractor Division of the National Implement & Vehicle Association. The latter body has appointed a committee to take up the matter of standardization with Department of Agriculture authorities. The committee which consists of four members is headed by E. J. Gittens, vice-president of the J. I. Case T. M. Co., other members being J. B. Bartholomew, president of the Avery Co.; Finley P. Mount, president Advance-Rumely Thresher Co.; G. J. Alexander, vice-president and treasurer Aultman-Taylor Machinery Co. The committee has not met as yet nor has it formulated any plan of procedure. However the matter has been placed before the Department of Agriculture, which had its representatives at a meeting of the Tractor Division of the N. I. V. A. two weeks ago.

Is An Absolute Necessity Say Users—And They Know

Ford owners practically drive their cars with their feet.

On the proper operation of the clutch pedal and the brake pedal, the safety of the passengers in the car depends.

UTILITY Pedals for Ford Cars make the clutch and brake pedals safe—keep the driver's feet from slipping. They are the width of the Pedals regularly furnished with higher priced cars.

The flange at the sides and the rubber covering make for absolute safety in operating Ford cars.

Ford owners who use them state in letters that they are *an absolute necessity.*

Ford owners who have never before used them at once recognize their worth, and buy them.

Ford Owners—ask your dealers for UTILITY Pedals today.

FRENCH TRACTOR DESIGN
Shows Lack of Uniformity

Spring Agricultural Exhibition at Saint-Germain Brings Out Varied Array of Machines of Four-Wheel, Track-Laying and Cable Type—Tractor Industry Getting Into Hands of Automobile Makers

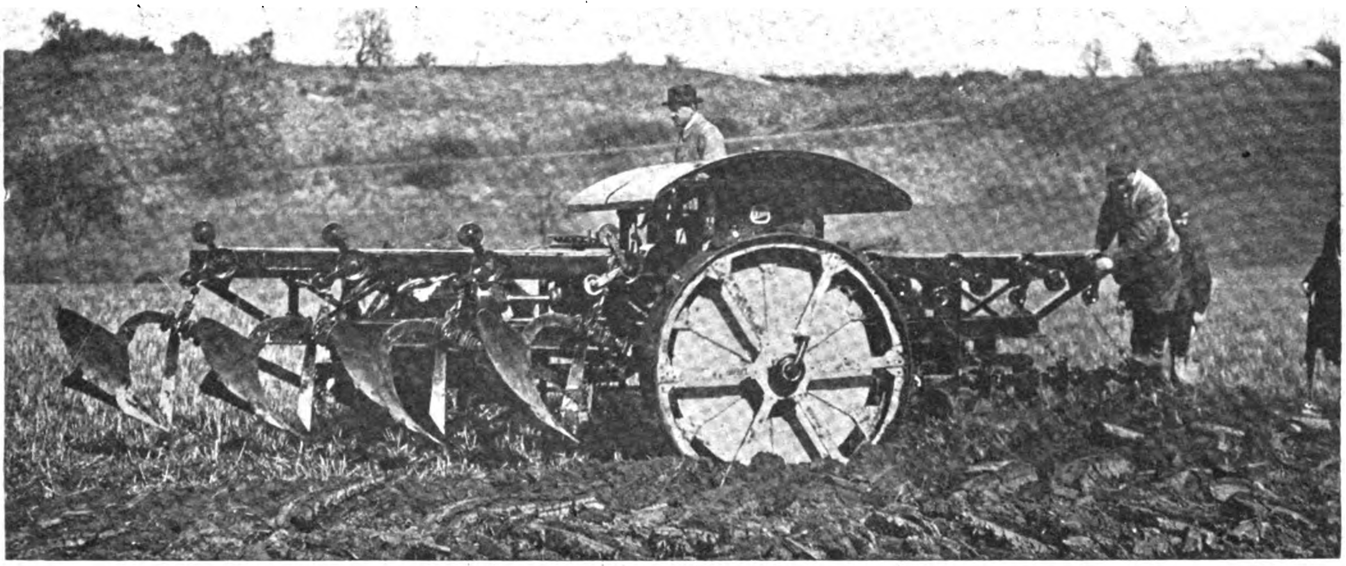
By W. F. Bradley

PARIS, April 12—France held her big spring agricultural tractor exhibition last week on a farm at Saint-Germain, 12 miles west of Paris. Unlike tractor demonstrations in America, it was not a competitive event, the machines merely demonstrating individually what they could do. Because of this the results were not entirely satisfactory. Not enough information of practical value to tractor users was developed.

Several things of interest to those familiar with tractor conditions in America, as showing in contrast tractor conditions in France, were emphasized by the meeting. Among them was the fact that the French automobile industry is actively taking hold of the tractor and appears likely to retain control of its manufacture in that country and that French machines are much more expensive than those made in America, ranging in price from $2,500 to $7,000 each. Another point of interest to which attention was again called by this meeting is the fact that few tractors are sold to individual farmers in France but rather to groups or co-operations of not less than seven men. Any such group can obtain from the French Ministry of Agriculture a subsidy varying from 30 to 50 per cent of the cost price of the machine. Purchasers under this system have to give a guarantee that the machine will be kept in repair and that a determined amount of land will be cultivated.

There were 34 firms present at the exhibition, some of them with two or three models of the same type. Seventeen of these firms were French, one English and sixteen

A demonstration of the Renault tractor at Saint-Germain



The new Delahaye is a three-wheel, self-contained plowing machine driven by a four-cylinder engine. Two of the driving wheels are in tandem on the side not shown

American. The American tractors were difficult to recognize from their catalog descriptions, for in most cases the French importers have re-christened them since taking them over. Frequently what at first sight would appear to be a French production turned out on closer examination to be a well-known American tractor. The leading American makes represented were Fordson, Bull, Cleveland, Heider, Case, Gray, Neverslip, Happy Farmer, Moline, Titan, Avery, Parrett.

Before the demonstration had been brought to a close it was realized that it should have been of a competitive nature in order to provide definite and practical information to possible purchasers. Information on price and delivery dates was obtainable, but on all other points connected with the machines, vague, contradictory and frequently foolish answers were given. Many of the makers could not answer elementary questions on gas consumption, drawbar pull, speed of operation on various land and under varied conditions, depreciation, possible cost of repairs, etc. A practical test would have given some sound basis on which to make comparisons and would have been of great value to those who are contemplating purchase.

This demonstration revealed that automobile manufacturers are interesting themselves in agricultural tractors, for all the new machines came from firms which before the war built trucks and touring cars only. The three most important new arrivals were Renault, Delahaye and Gnome & Rhone. Other big firms were De Dion Bouton, Latil, Schneider, Peugeot and the Paris General Omnibus Company. The Gnome & Rhone Company is the well-known aviation engine firm, which possesses in the suburbs of Paris a couple of the most modern factories to be found in Europe.

There is no uniformity in the minds of European manufacturers regarding the best type of agricultural tractor. They are all using four-cylinder vertical truck type engines, and they are all putting as good work in their tractors as in the best trucks, but beyond this the greatest diversity exists.

Fiat, who is representative of Italy, and Austin, who is representative of England, have adopted the four-wheel frameless type of tractor. Renault, the biggest automobile manufacturer in France, has adopted the self-track-laying type. Delahaye, one of the biggest truck makers in France, has built a self-contained plowing machine, with plows placed in front and in rear. Latil, the most important four-wheel-drive tractor maker, has

a self-contained machine with plow in the rear. De Dion-Bouton has adopted the cable system of plowing with fixed tractors. The big Schneider company has both an endless track type and a rotary plow. The Paris General Omnibus Company has adopted the English Saunderson type of direct towing tractor. Filtz has a special type of cable machine, the ends of the cable being fixed, and the machine hauling itself along by means of winding drums.

The Cable Type

In the cable class alone there are three distinct methods, and both gasoline and electricity are employed as the motive power. In the first class is the De Dion-Bouton type, where the two machines take up a position at the extremities of the field and haul the plow across the land by means of a cable and winding drums. In the Doisy system the tractor runs across the field, unwinding its cable as it goes, then anchors itself and hauls the plow by means of its winding drum. Finally the Filtz type has the ends of the cable fixed at each extremity of the ground and hauls itself along by means of winding drums, with the plow in direct tow.

All the leading European makers, Fiat, Renault, Delahaye, De Dion-Bouton, Latil, Schneider, use their truck engines with enclosed valves on one side, high-tension ignition, forced feed lubrication and automatic carbureters for gasoline or benzol. Air cleaners are not used by anybody, for the climate of France and England is so damp that a tractor aspires less dust than a truck on the road. Nobody has made any provision for night plowing, for this does not appear to have entered into the habits of the French farmer.

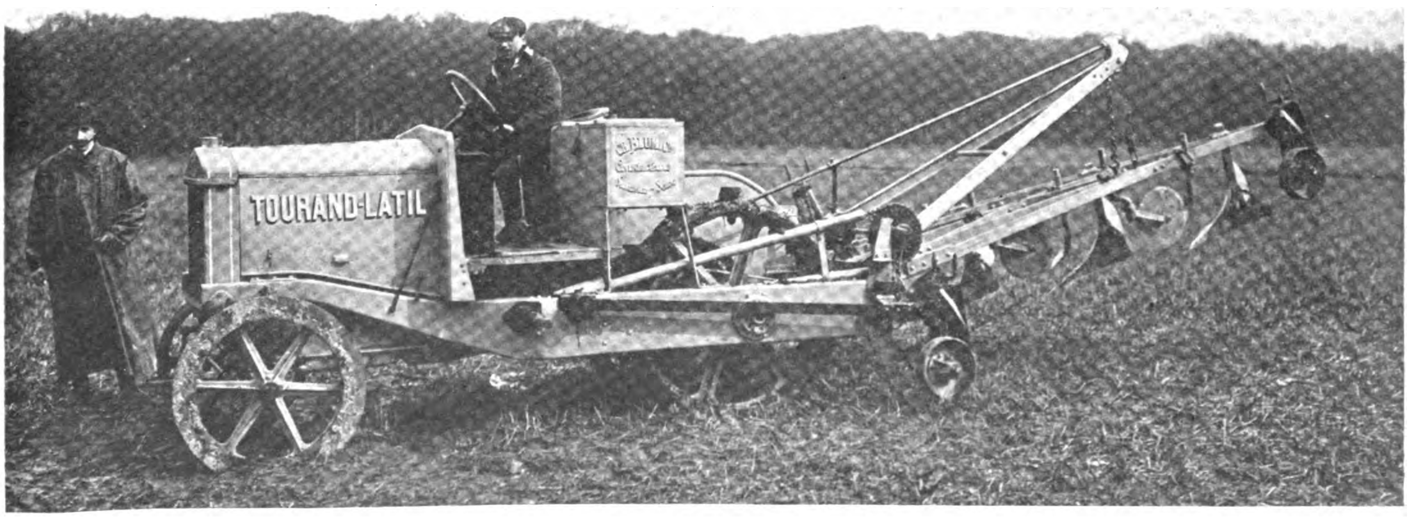
European machines are costly. The Delahaye is listed at $7,000, calculating at the nominal rate of 5 francs to the dollar. This price, of course, includes the plows, as the machine is self-contained. The Renault creeper type of tractor is sold for $5,700; the Fiat runs about this price and the Latil is a little higher. Some of the cheapest direct tractors are selling at $2,400 to $2,500.

The Renault, a Converted Tank

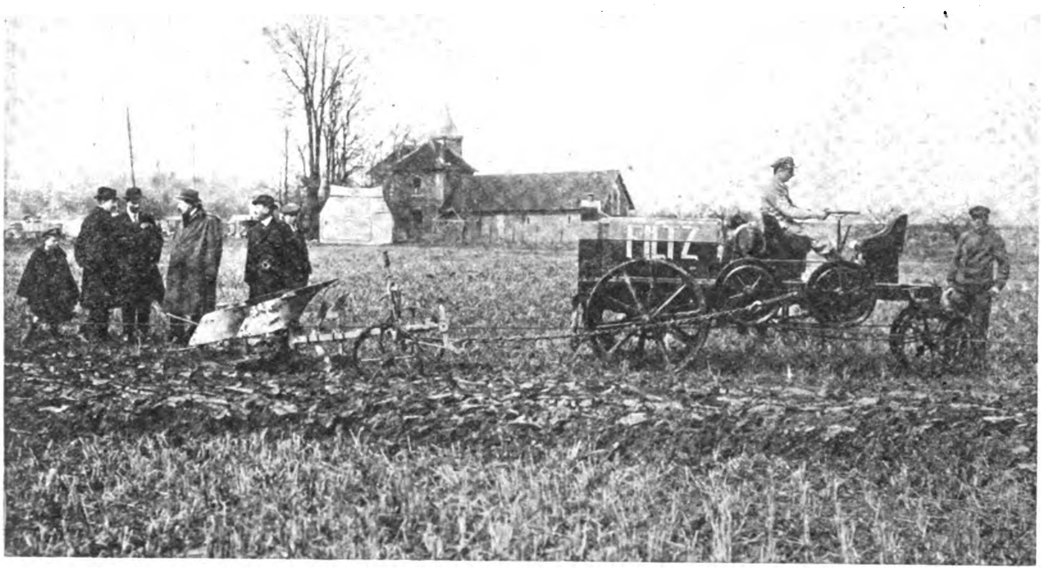
Since Nov. 11 Renault has transformed his army tank shops into a tractor producing plant, and at the present moment is turning out 100 agricultural tractors a month. The assembly of these tractors is carried out in a very modern method on a moving rail. The Renault tractor is the direct outcome of the two-man tank built in large quantities during the war. The engine is exactly the same, being a four-cylinder block type of 95 by 160 mm.

An American representative—the Moline—at Saint-Germain

The new Renault incorporates the general features of the small tank



The Tourand-Latil tractor approaches the automobile type in general design, but the plows are permanently attached



The Filtz tractor is a variation of the cable type. The cable is anchored at each end and the tractor pulls itself along by means of it

bore and stroke. The gasoline feed adopted on the tank to assure a flow of gas to the carbureter whatever the inclination of the machine has given place to direct flow by gravity. The special lubricating system, however, with dry base chamber, has been retained.

Engine Mounted at Front

Instead of the engine being at the rear, as on the tank, it is mounted at the front, under a hood, with the radiator behind it, inclined at an angle of about 45 deg. This radiator is of the gilled tube type, with a ribbed aluminum header tank, and has a draft of air drawn through it by means of the flywheel fan. In this way no air is drawn in over the engine.

From the engine the power is transmitted through an inverted leather faced cone clutch to a four-speed gearbox, then by a couple of Ferodo lined lateral clutches and a train of reducing gears to the two driving sprockets, one on each side, which transmit the movement to the endless bands. As in the case of the tank, the tension of the endless band is maintained automatically. Indeed, the whole of the track-laying mechanism is the same in general design as on the tank. Naturally, the parts are smaller and lighter, the bands, for instance, having a face width of 7 in. as compared with 13½ in. for the tank.

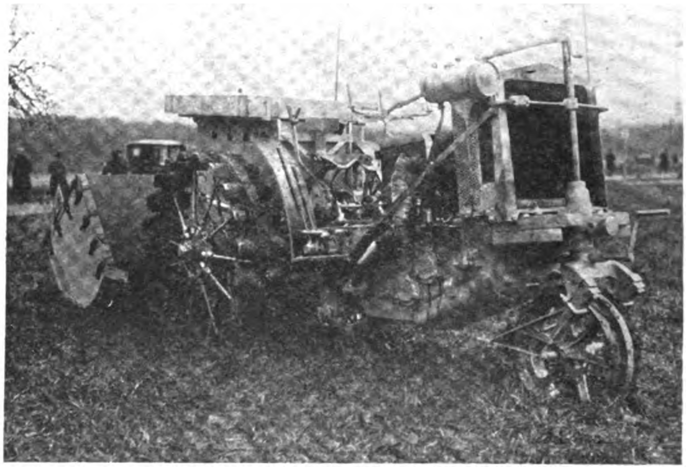
Steering is by means of a couple of levers mounted on a vertical column. By pulling the right-hand lever the lateral clutch on that side is withdrawn and the entire tractor made to turn to the right. The power plant is mounted in a channel section frame which is attached at the rear to the endless track mechanism and secured at the front by an inverted semi-elliptic spring.

Renault Tractor Dimensions

Overall dimensions of the Renault tractor are 135 by 69 in. The endless tracks have a length of 64 in. in contact with the ground; total weight of the machine is 6000 lb., and drawbar pull 5500 lb. The catalog price of the tractor is 28,000 francs, or $5,600 at nominal rate of exchange.

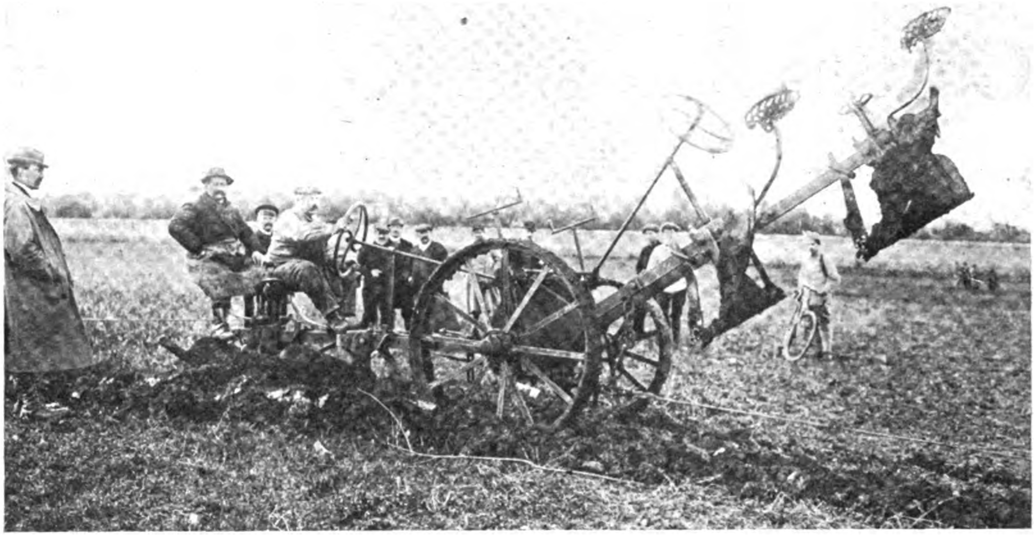
The new Delahaye is a complicated, well-built, three-wheel, self-contained plowing machine. The four-cylinder engine is the 4-ton truck type of 100 by 160 mm. (3.9 by 6.29 in.) bore and stroke, placed across the machine. Two of the driving wheels are in tandem on the outside, and the third wheel, which is also a driver, is centered between the two others. Mounted transversely in the frame, with the radiator placed just back of the single wheel, is the four-cylinder engine, clutch and gearset, this latter providing two speeds ahead or reverse. The drive is taken to the wheels in tandem by means of a couple of horizontal shafts, one running ahead and the other astern, to worm gearing, and finally by enclosed internal spur gears. The single wheel receives its drive more direct by means of a transverse shaft parallel with the crankshaft and enclosed internal gear.

The two wheels in tandem are steerers as well as drivers, but the turning angle is very small, and does not



A three-wheel machine with rotary plow built by the Schneider company

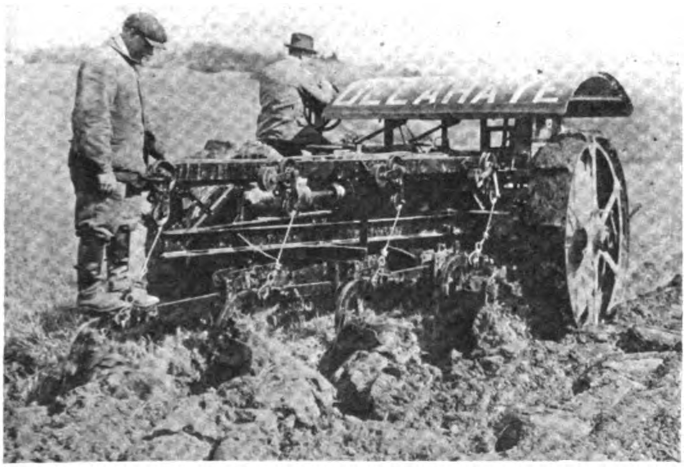
One of the 16 American makes represented—the Case



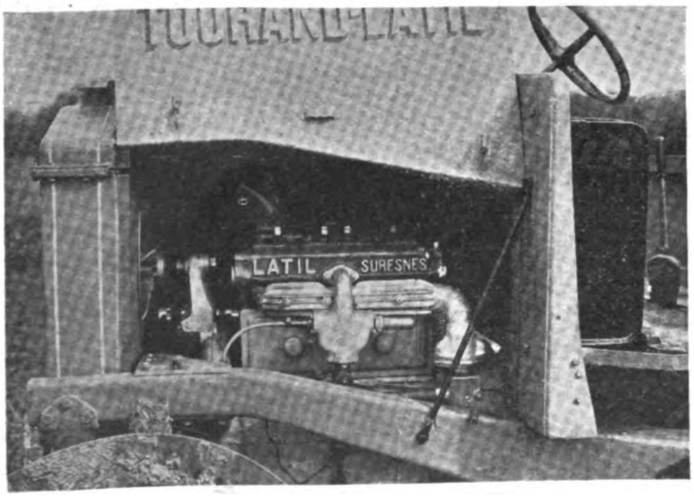
The only electrically pulled cable plow exhibited at Saint-Germain. Electric winches at either end of the plot to be plowed pull the plow first one way and then the other

appear to give anything more than is necessary to change position for a fresh furrow when the end of the ground is reached. The operator sits on the outside of the machine, in the position farthest removed from the furrow, and has a couple of steering wheels mounted on the top of a vertical column. The steering is naturally duplicated, there being two main steering arms and two fore and aft connecting rods. As the steering pivots are on the inside of the wheels and the fore and aft rods are on the outside, connection is made by carrying the connection through the wheel hub. On the opposite side a similar method is adopted when the starting crank is carried through the hub of the single driving wheel.

A four-bottom plow is mounted at each end of the machine, and each one can be raised mechanically by means of a winch. The single driving wheel has a diameter of 60 in. and a face width of 11.8 in. The two wheels in tandem have a width of 51 in. Total weight of the machine with plows is 8800 lb.



The Delahaye is a four-furrow machine with plows on each end



Valve and manifold side of the four-cylinder engine fitted to the Tourand-Latil tractor

De Dion-Bouton produces two types of cable plowing machines. One of these is rated at 50 hp. and has a four-cylinder engine of 4.8 by 5.9 in. bore and stroke; the smaller one, rated at 30 hp., has a four-cylinder engine of 3.9 by 5.5 in. bore and stroke. The method of operating is to place a tractor-winch at each end of the machine and to haul a double plow across the land. Each tractor has its engine in front, winding drum in the center, and a small platform at the rear. The big tractor takes the drive to the rear wheels by means of transverse shafts and internal gears, exactly the same as on De Dion-Bouton trucks, but the number of gears is reduced to two and reverse.

A 15-mm. steel cable is used, having a length of 550 yd., with a breaking strain at 26,000 lb. The drawbar pull is 7000 lb. average, this allowing plowing to be carried out, in moderate ground, with a six-blade plow to a depth of 9.8 in., giving a width of 70 in., at a speed of 2.3 to 2.8 miles an hour. With three blades, and plowing to a depth of 11.4 in., the width of land operated on is 47 in. Gasoline consumption is said to be 3 to 3¾ gal. per acre with a drawbar pull of 7000 lb., using a six-blade plow and plowing to a depth of 7 to 9½ in. Under these conditions two of the big machines working together will cover 12 acres per day of 10 hours.

The smaller De Dion-Bouton machine differs from the larger by reason of the adoption of chain drive, with only a single gear ahead and one reverse. The winding drum is provided with 440 yd. of 13-mm. steel cable, having a rupture point at 20,000 lb. The drawbar pull is 4400 lb., and the plowing speed 2.3 to 2.7 miles an hour.

The Gnome and Rhone

The new tractor for which the Gnome & Rhone Company is responsible, or rather will be responsible, for the exhibition model appears to be an experimental type built outside, is a four-wheel driver type. At the trials a machine was shown with a twin cylinder vertical engine, but it was explained that this will be replaced by a four-cylinder vertical slow-speed engine of 16-20 hp., water cooled, with forced feed lubrication. The tractor, which is of comparatively light weight, namely 2800 lb.,

Curtiss K-6 and K-12 Aircraft Engines

Of Aluminum Construction with Steel Cylinder Liners—Outstanding Features Include Counterbalanced Crankshaft, Double Valves in Heads; Overhead Camshafts and Bevel Gear Camshaft Drives—Herringbone Gear Reduction on the K-12

DURING the latter part of the war the Curtiss Aeroplane & Motor Corp., Garden City, L. I., and Buffalo, N. Y., developed two high-powered airplane engines of which it has been possible to obtain complete technical details only quite recently. One is a 6-cylinder and the other is 12-cylinder type, as indicated by the designations K-6 and K-12. Both have cylinders of the same dimensions and are identical in design except for the greater cylinder number and output of the twelve and for the fact that the latter is a V-type engine while the K-6 is a vertical type. The general construction may be briefly described as follows: Cylinder blocks and top half of crankcase are in one casting of aluminum. The cylinder heads form a separate aluminum casting which is bolted to the cylinder block. Steel cylinders or liners are used, six of them being screwed into each cylinder head. The cylinder heads are then placed over the cylinder blocks, and watertight joints between the steel liners and the aluminum blocks secured by means of packing.

In the K-6 the cylinders are, of course, set all in line, while in the K-12 they are set at an angle of 60 deg. This is the natural angle for a 12-cylinder engine, as it gives uniformly spaced explosions, though the practice often has been departed from in aircraft engine design in order to decrease the head-on air resistance. The bore is 4½ in. and the stroke 6 in., which gives a piston displacement of 572.4 cu. in. for the K-6 and 1144.8 cu. in. for the K-12. A power curve of the K-12 has been published which shows an output of 420 hp. at 1600 r.p.m.

The K-6, which is a direct driving engine, weighs 420 lb. dry, with all equipment except the exhaust manifold (14 lb.). This is 0.735 lb. per cu. in. displacement, and slightly over 2 lb. per hp. The K-12, which is a geared engine, weighs 720 lb. dry, with all equipment except the two exhaust manifolds (28 lb.). This is 0.63 lb. per cu. in. displacement and well below 2 lb. per hp.

The cylinder liners are made of hydraulic forgings of high-carbon steel, which are first rough bored and rough turned, and then subjected to heat treatment. The liner is then reamed out to within a few thousandths in. of its finished size, and the outside is finish-turned to a wall thickness of 5/64 in., leaving stiffening flanges every 1 in. of length, as well as a packing retaining flange at the bottom and a central stud at the top. The upper end of the liner, forming the combustion chamber, is slightly enlarged and is turned with a screw thread on its outside by means of which it is screwed into the cylinder head. The liners are of thimble form, having a closed head, in which there are four openings for the four valves respectively.

The cylinder head is an aluminum casting, in which are formed the inlet and exhaust valve passages, the combustion chamber recess and the necessary water spaces.

Left—Distributor end of K-6, showing magnetos driven by cross-shaft, arrangement of camshaft and pump drive

Right—Side view of the K-6

The combustion chamber recesses are internally threaded and the six cylinder liners are screwed into the cylinder head, the head casting and the six liners together forming a complete unit. The head casting extends somewhat beyond the section of the cylinders, matching up with a flange cast on the upper end of the cylinder block, and is held in place on the cylinder by means of studs, screwed into the cylinder head, passing through the flange on the cylinder block, and having nuts on their lower end.

In order to insure intimate contact of the head portion of the steel liner and the head casting, the liner is formed with a threaded stud at the center of its head which passes through the combustion chamber wall in the cylinder head casting, and is drawn up by a nut. The threaded portion of the liners is made a tight fit in the threaded portion of the cylinder head, and this is depended on to give good heat conduction.

Liners Assembled with Cylinder Head

When the six liners have been assembled with the head, the assemblies are finished on all surfaces which have to be very accurate. The upper and lower faces are machined to absolute parallelism, the cylinder liner bores are ground to size, the valve ports bored and seated, and the spark plug bushings inserted. These bushings, which are of bronze, are cut with a tapered thread on the outside, and with an 18 mm. standard spark plug thread on the inside. When these bushings are screwed tightly into the cylinder heads, there is said to be no danger of their coming loose while unscrewing the spark plug.

The same size of crankshaft is used in both engines, although the K-12 develops about 100 per cent greater power. The crankshafts are made of 35-45 point carbon, chrome nickel steel, by the drop forging process. The forgings are first rough-machined, then heat-treated and lastly finish-machined. The crank is of the standard 6-cylinder type with the two center throws in one plane. Crankpin bearings are 2½ in. in diameter by 2⅛ in. in length. There are five main bearings, one front, two intermediate and two rear bearings, one of the latter on each side of the reduction gear in the 12-cylinder model and of a deep-groove radial ball bearing serving as thrust bearing in the 6-cylinder model. The dimensions of the main bearings are as follows (front to rear): 2½ x 2 in., 2½ x 2 in., 2½ x 2 in., 2½ x 2¾ in., 2½ x 1⅝ in. All crankpins and all main bearings are bored out to a diameter of 1⅞ in.

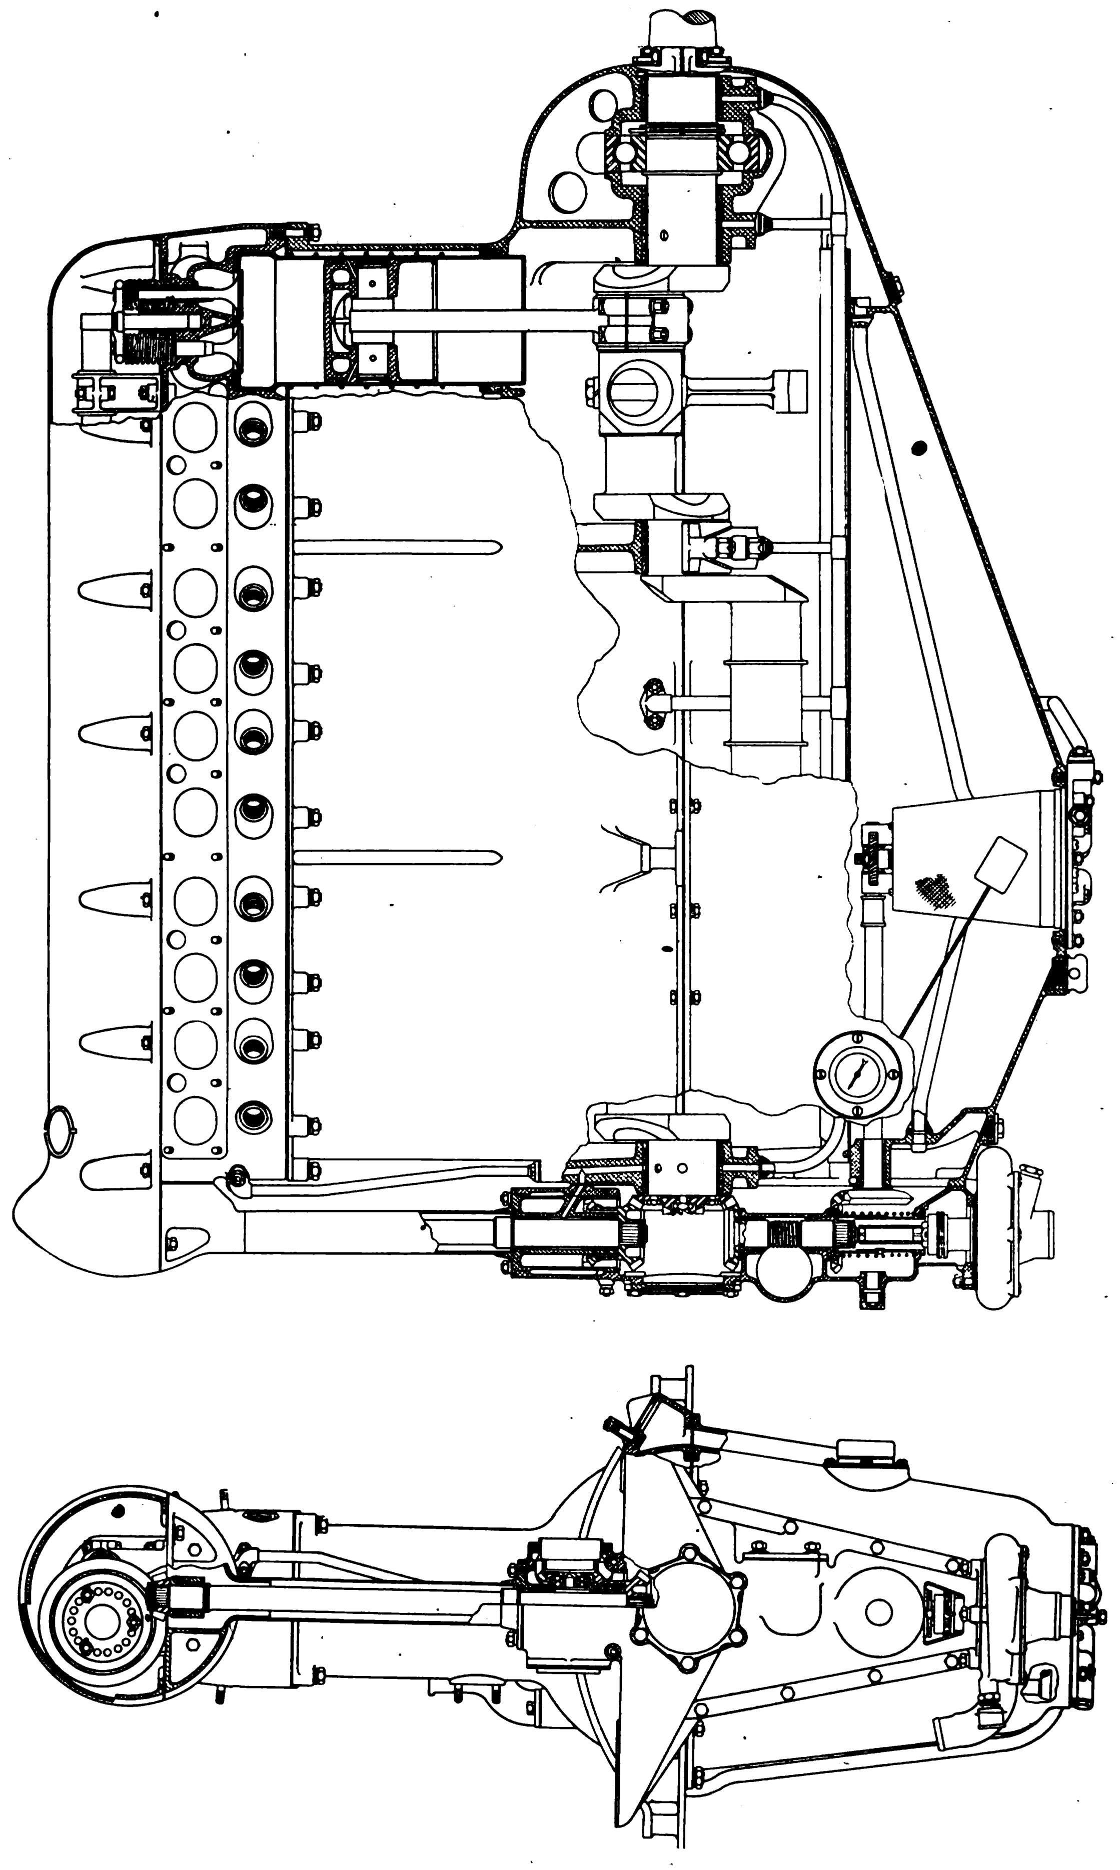
Crankshaft Carries Balance Weights

The problem of crankshaft balance has been thoroughly considered, and on the two long arms of the crank there are balance weights to insure perfect running balance. These two long crankarms naturally produce an unbalanced moment around the crank axis, which in the conventional 6-cylinder crankshaft is balanced by a spool between the two center crankpins. However, this balancing weight between the two center pins is a source of weakness, owing to the bending moment produced by the centrifugal force on it at high speed. Another disadvantage of this method of balancing a 6-cylinder crankshaft is that, whereas the unbalanced moments are produced between the first and second and between the fifth and sixth crank throws respectively, it is attempted to neutralize them by a moment created by a balance weight between the third and fourth crank throws. Hence the opposing moments are in different planes, separated by one of the main bearings of the crankshaft, and this naturally imposes additional load on the bearings. By applying balance weights directly to the sides of the long crank arms their unbalanced moments are eliminated, and the double center throw of the crankshaft can be made without the balancing spool, whereby the centrifugal force on it is reduced.

To obtain the greatest possible balancing effect with the least weight, aluminum spacers are inserted between the steel balance weights and the crankshaft, the balance weights being held to the crankshaft by steel bolts.

At the forward end of the crankshaft an internal flange is machined to which the combined camshaft driving bevel gear and starting ratchet is secured by means of 6 bolts. At the rear end of the 6-cylinder crankshaft a deep groove radial type ball bearing is mounted between

Curtiss K-6 Airplane Engine



This view shows details of the camshaft and accessory drive, the crankshaft, the cylinder liners, pistons, valves and oiling system. The cylinder dimensions are 4½ x 6 in.

a flange and a nut, to take up the end thrust of the propeller. The rear end of the 12-cylinder crankshaft is turned with an integral flange, to which is bolted the driving member of the herringbone reduction gear, by means of nine 7/16-in. alloy steel bolts. The driving gear is cut with 5-7 pitch stub teeth, the teeth of the two sections of the gear being staggered.

Crankcase Cast Integral with Cylinder Block

In both models the upper half of the crankcase is cast integral with the cylinder block, and naturally it is different in design for the two, but the lower halves are the same in both engines. The cylinder portion of the casting forms only the jacket wall, the cylinder wall proper being formed by the steel liners. At the bottom of the cylinder there is an internal flange, between which and an external flange at the bottom of the steel liner is inserted a cork packing ring to insure a water-tight joint. Between the top of the cylinder casting and the cylinder head there is a copper-asbestos gasket. There is direct communication between the water space of the cylinders and that of the cylinder heads through drilled holes. It is claimed for this construction that, with the bolted joints between the cylinder block and the crankcase eliminated, a very rigid structure is obtained, besides which the cooling water comes in direct contact with the steel cylinder liner, which insures very effective cooling.

All main bearings are supported by the upper half of the crankcase, on partition walls of same. The caps of the bearings are of very substantial design, having an I section, and are held in place by 4 studs, fitted with casttellated nuts and cotter pins. The studs of the rear bearings on the K-12 extend entirely through the gear housing and crankcasing, having nuts applied to them at both ends. In this way the aluminum housing is relieved of the strain due to the tooth pressure of the reduction gear. In order to prevent disalignment of bearing caps, they are formed with large keys. The cap of the reduction gear housing is designed with recesses for the nuts on the retaining bolts, and all ribs are on the inside, so that a very smooth exterior is obtained. In addition to the "through" bolts holding the rear bearings in place, several other studs are used for retaining the reduction gear housing cap.

All bearings are of the bronze-back, babbitt-lined type, tin babbitt being used, and are held from turning in the bearings by means of brass screws with countersunk heads. No shims are used between the halves of the bearing, the two half bushings being in direct contact with each other. All journals of the crankshaft are ground accurately to size, and as the bushings are reamed in a precision fixture, there should be the same clearance on all journals of the shaft.

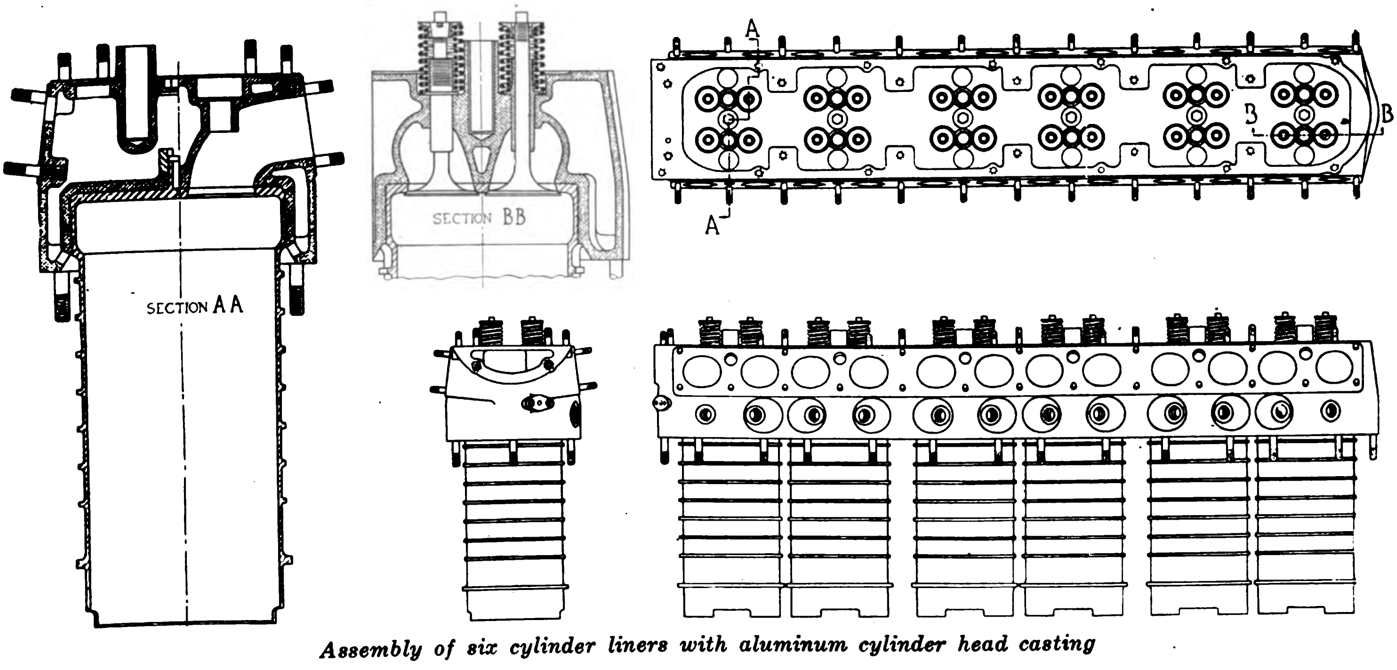
Pistons of aluminum alloy are used. With a view to quickly carrying off the heat absorbed by the cylinder head, the pistons are heavily ribbed, there being one circular rib concentric with the skirt, and, in addition, a number of radial ribs which extend the whole length of the skirt and help to transmit heat from the head to the skirt.

There are three piston rings on the piston above the pin. Of these the upper two are 1/8 in. wide each, while the lower one is 3/32 in. wide. Directly below the lower ring there is an oil groove from which inclined holes are drilled to the bearing surfaces of the piston pin in the piston bosses. The piston pin floats in both the piston and the connecting rod and is held against endwise motion by a snap ring in each piston boss.

Connecting Rods I Section

The connecting rods are I-section drop forgings of alloy steel. They are heat treated and machined all over. In the 12-cylinder model, where the pistons of oppositely located cylinders work upon the same crankpin, there is one master rod, which is provided with a lug at its big end to which the other rod of the pair is pivoted. A wristpin for the small connecting rod is secured in this lug by means of a clamp screw, and the small rod straddles the lug. Bronze bushings are used in the wristpin bearings and also in the upper ends of all connecting rods.

As already mentioned, there are two inlet and two exhaust valves in each cylinder, and the two sets are interchangeable. These valves have a clear diameter of 1⅝ in., and the seat is 1/16 in. wide. Cast iron bushings are inserted into the valve stem guides in the cylinder head, these bushings being fitted to a slight taper. Each valve has two concentric springs of alloy spring steel. The inner spring rests against a flange on the valve guide bushing, while the outer spring rests in a recess in the head casting. The spring washers on the ends of the valve stem are backed up by nuts secured by straight



Assembly of six cylinder liners with aluminum cylinder head casting

pins, so that the pressure of the springs can be adjusted.

There are two camshafts extending across the top of the cylinder heads, the whole length of the engine. The cams do not act directly upon the valve stems, but through the intermediary of cam followers in the form of yokes, each of which embraces the tops of two valves of the same kind. These cam followers are provided with stems sliding in a bushed guide between the valves. There are adjusting screws in each arm of the cam follower yoke, by means of which the valve clearance can be adjusted. When the adjustment is made the adjusting screw is locked by means of a clamp screw.

In the 6-cylinder model, the camshaft is driven from a bevel pinion on the forward end of the crankshaft through a vertical shaft extending up the forward end of the engine. As this vertical shaft is located in the center plane of the cylinders, whereas both of the camshafts are outside this center plane, a pair of skew bevel gears has to be used at the upper end for driving one of the camshafts from this vertical shaft. The other camshaft is driven from the first one through a pair of helical gears. In the 12-cylinder model the arrangement is naturally somewhat different. Here an intermediary vertical shaft is used, which receives its motion from the crankshaft through a pair of bevel gears. This shaft extends up from the crankshaft, and near its upper end carries two bevel pinions, the lower of which meshes with two magneto driving gears and the upper with gears on the two camshaft driving shafts. This intermediate shaft is mounted in a long plain bearing at its lower end and in a ball bearing at its upper end.

Camshaft Driving Shafts Inclined 45 Deg.

What gives the Curtiss K-12 a somewhat unusual appearance is the fact that the camshaft driving shafts at the forward end of the engine do not run parallel with the axes of the cylinders, but are inclined 45 deg. to the vertical. These camshaft driving shafts are mounted in ball bearings at both ends. In the K-12 the axis of the camshaft driving shaft intersects the axis of the driven camshaft, and, therefore, straight bevel gears are used at the upper end. The gear at the lower end of the camshaft drive shaft is integral with the shaft, while that at the upper end is fitted to it by means of muliple splines.

One camshaft is located directly in line with the exhaust valves, and the other in line with the inlet valves. The two shafts are geared together by means of helical gears. These gears are indexed to the cams, and, as the thrusts on the two shafts are in opposite directions, the timing and longitudinal positions of the shafts are accurately maintained. The bevel gear through which the camshafts are driven is bolted to a flange on the forward end of the exhaust camshaft, and timing is effected by means of a set of vernier holes. The thrust is taken on the back of the flange. The camshafts are supported in bearings mounted in aluminum brackets, one set of bearings between each pair of cylinders. The shafts are drop forged from low carbon steel, carbonized and hardened. They have the cams, the two helical gears and the necessary flanges forged integral with them. The cams are of the constant acceleration type, and give a lift of 0.406 in. On the intake camshaft there is an eccentric which may be used for driving a pressure air pump.

Directly in line with the intermediary shaft for driving the magnetos and camshaft driving shaft, but below the axis of the crankshaft, there is another vertical shaft which is used for driving the water pump, oil pumps and the tachometer. This shaft is driven from the same bevel pinion on the forward end of the crankshaft that drives the intermediary shaft. The water pump is located at the bottom of the accessory driving shaft and is driven from it through a coupling joint. The gear housing is formed with pads over which the water pump, the tachometer drive housing, the magneto drive housings and the camshaft drive housings may be bolted. Magneto brackets are cast integral with the driving gear housing.

Zenith Carbureters

The K-6 is equipped with one and the K-12 with two 52-mm. Zenith duplex aero carbureters. Each carbureter furnishes mixture to three cylinders through a water-jacketed manifold. Ignition is by high-tension magnetos, of which two are used on both the 6-cylinder and 12-cylinder models. The magnetos are of the two-spark type, and each cylinder is provided with two spark plug bushings. The spark plugs are connected to the magneto distributers by cables enclosed in rectangular micarta tubes.

Lubrication is entirely by force feed, and, in addition to the pumps forcing oil to the bearings, there are auxiliary pumps which remove oil from the crankcase above the oil pan deck. The pumps are located in the lower part of the crankcase and are driven from the accessory driveshaft through a horizontal shaft. All of the gears are arranged in a single unit, which comprises two pumps for forcing oil to the various bearings, and a triple pump for emptying the oil out of the crankcase. Combined with the pump unit are the gear shafts and spiral gears for driving the pump, and the whole casting is surrounded by a fine mesh wire screen through which all of the oil is filtered. This screen is properly reinforced so that it cannot be damaged by excessive suction in case it should become clogged. Within the cover of the pump are the by-passes and spring-retained conical relief valves, which regulate the pressure under which oil is forced to the bearings.

The pressure pump draws oil from the sump through the screen and delivers it into the oil feed line. This line has a flange connection to the upper half of the crankcase, and at this point the oil enters the main distributer, which delivers oil to all main bearings. All of the journals of the crankshaft are hollow, and the main journals are provided with end caps. From these journals the oil is carried to the connecting rod bearings through small oil tubes built into the crankshaft. In the case of the K-12, the bearing at the lower end of the small connecting rod is fed from a bleeder hole in the connecting rod bushing. In the case of the K-12 also, the propeller shaft is oiled by a portion of the oil being by-passed around the bushings of the two rear crankshaft bearings through copper tubes to the propeller shaft bearings. A bleeder tube from the front propeller shaft bearing lubricates the upper reduction gears.

At the front end of the engine, oil from the front bearing bushing is carried through drilled holes and outside tubes to the cylinder heads. There the tubes have a sliding point with the revolving camshafts, which are drilled out, and the oil is fed to the camshaft bearings through the hollow camshafts and radial holes drilled through the camshaft walls. Provision is also made for lubricating the camshaft bevel gears and the valve stems, cam followers, etc. Any excess oil in the cylinder head runs down the camshaft drive housing and lubricates the bevel gears on the vertical shaft, and some of it is caught in two oil cups on the vertical shaft bearing and lubricates this bearing. The rest runs down into the front end of the engine. The sumps form a sediment chamber which may be emptied through a hole fitted with a screw plug.

An important feature of the lubricating system is an

Winton Diesel Engines

Marine-Type Six and Eight-Cylinder Engines Built in 200, 300 and 500-Hp. Sizes —Twin Valves, Enclosed Base, Pressure Lubrication and Other Features Indicative of Automobile Influence

AUTOMOBILE practice has been applied to a notable extent in the development of the new Diesel engines by the Winton Co., Cleveland. The result has been a marked similarity of appearance, and in many cases of design, with what has come to be recognized as standard characteristics.

There are three sizes of Winton Diesel engines. The smallest develops 200 hp. at 250 r.p.m., and has 11 x 14 in. cylinders. The intermediate size is of 300 hp. and, the same as the small type, has six cylinders, the cylinders in this case being 13 x 18 in. The same cylinders are used in the largest type, which is an eight-cylinder, rated at 500 hp.

Enclosed crankcases, trunk-type pistons, and crankshaft bearings solidly mounted in the upper half of the crankcase with bolted-on caps are the chief characteristics of the Winton Diesel engine as distinguished from other types.

The engine operates under 550-lb. compression, which is sufficient to cause preignition, thereby dispensing with electrical ignition. The fuel pump is a plunger type, with one plunger for each cylinder. It delivers the fuel to the fuel injection valve under a pressure of from 1000 to 1200 lb., depending on the pressure of the fuel injection air. The stroke of the fuel pump is constant, the amount of fuel delivered being controlled by the early or late closing of the pump inlet valve by the governor. On the Winton Diesel engines an adequate supply of fuel is always assured by the fact that the fuel oil is lifted to the fuel pump from the tank by 10 to 15 lb. air pressure, which is sufficient to secure plenty of fuel at the pump inlet valve.

Since these engines work on the true Diesel cycle, the fuel is forced into the cylinder against a compression of 550 lb. by the use of air at about 1000 lb. pressure. This not only carries the fuel into the cylinder but breaks it up into very fine particles so that combustion is complete. The high-pressure air for this purpose is obtained from a three-stage air pump mounted at the front end of the engine.

This pump is of interesting design, the piston being of the trunk type, operated by a connecting rod which is a duplicate of the connecting rods in the power cylinders, and a single-throw counterweighted crankshaft, which is bolted to the front end of the main crankshaft. The throw of this single crank is somewhat greater than that of the power shaft.

The capacity of the air compressor, being considerably in excess of that required for the injection of the fuel, provides for the initial charging and maintenance of pressure in the storage tanks, or air bottles, which are used for starting the engine. There are two sets of these air bottles, one carrying the air at about 600 lb. pressure per square inch, which is admitted to the cylinders in turn, to force the

pistons down, starting the engine rotating. The second set of air bottles carries air at 1000 to 1200 lb. per square inch. This is used to inject the fuel into the cylinders, thus starting the engine running under its own power. As soon as the fuel is injected the compression pressure raises the temperature to such an extent that it at once starts to burn.

It will be noted from the following description that a great many of the structural points are very similar to those found in motor truck and motor car practice. The crankcase is of gray iron and cast in one piece, of skeleton construction, the sides having large openings opposite each throw of the crankshaft, these openings being provided with cover plates, affording easy access to all parts of the interior. A main bearing for the crankshaft is provided on each side of each throw, each bearing being supported by heavy ribs so as to give the desired rigidity. The lower part of the crankcase forms an oil pan, which, as in motor-car practice, extends from the timing gear in the front to the rear of the thrust bearing at the back end of the engine. This gives a fully enclosed oiling system.

The cylinders are cast individually, with integral water-jackets. There are large cover plates provided on the water-jackets so as to permit them to be cleaned readily if necessary. The cylinders are bored and ground.

The cylinder heads are secured to the cylinders by studs and nuts, so arranged that the pressure is uniformly distributed. Each cylinder head carries five valves—two for the incoming air, two for the exhaust and one for the injection of the fuel. The head also carries the rocker mechanism by means of which these valves are operated.

The pistons are about 75 per cent greater in length than in diameter. The piston-pin bosses are located about one-third of the diameter up from the bottom of the piston, which brings them about the center of the effective bearing surface. The length of the bosses is such that the bronze bushings can be inserted from the inside. As each bushing is flanged it is thus locked against endwise motion when the connecting rod is in place. The piston tops are dished, giving the necessary compression space, and there are heavy ribs from the top of the piston to the side walls and the bosses. The piston is also strengthened by a rib around its inside just above the bosses.

To prevent oil working up above the piston rings a groove is turned immediately below the lowest ring, and from this groove a number of holes lead back into the inside of the piston. To prevent oil splashing up under the lower side of the head, where it would be burned and blackened, the hole through the rib around the inside of the piston is enclosed by a sheet-metal plate.

Each piston has a hole through each side, midway between the pin bosses and slightly above them, through which it is possible to handle the bolt which clamps the upper end of the connecting rod around the piston pin.

The connecting rods are I-section forgings, split at the upper end and clamped around the piston pins, and formed into a T-head at the lower end, to which two half-boxes and a supporting cap are bolted. Each rod has an oil tube connecting with the groove in the upper half-box and leading upward to the piston pin. The piston pin itself is hollow, with its ends plugged, and is drilled near each end so that oil is fed directly to the bushings in the piston. The tube and piston pin are thus filled with oil under pressure from the pump, and adequate lubrication of the piston pin is insured. The piston pin is case-hardened and ground and bears on bronze bushings pressed into the bosses in the piston.

The crankshaft is made in three pieces, two sections having each three or four throws for the power cylinders, and the third section having a single throw for the air compressor. These sections are flanged and bolted solidly together before being assembled into the crankcase.

From each main bearing of the shaft a hole is drilled through the adjacent web to the crankpin. These holes register with grooves in the main and connecting rod bearings so that the connecting rod lower bearings are also lubricated under pressure directly from the pump. Each bearing has an individual oil lead to a header running the full length of the crankcase. This header is connected to a two-cylinder reciprocating oil pump which maintains con-

Left—One of the cylinders from the Winton Diesel engine
Above—The cylinder head, showing the five valves, two for incoming air, two for exhaust and one for fuel injection

stant oil pressure on the bearings. Further details of this pump will be given later.

The camshaft is supported in a long box-shaped casting open at the top, which in turn is supported on brackets from the cylinders. This trough is partly filled with oil, insuring ample lubrication to the cams and camshaft bearings. The driving gears are fed directly with oil under pressure from the pump.

The camshaft is driven by bevel gears from a vertical shaft near the center of the engine, which in turn is driven from a lay shaft and a train of spur gears at the front end.

The camshaft is provided with two complete sets of cams, for forward and reverse motion respectively. Shifting the shaft endways by means of a handwheel and suitable mechanism brings either set of cams into operation. The shift from full speed ahead to full speed astern is guaranteed in 6 sec., and is frequently accomplished in 5 sec. Considering the weight of the parts which must be brought to rest and started in motion in the opposite direction, this is a wonderful performance.

Reversing the Engine

The procedure required to reverse the engine is as follows:

1—Close fuel-oil supply valve.
2—Shift camshaft.
3—Open fuel-oil supply valve.
4—Open valves controlling starting air.
5—Close starting air valve.

Each pair of inlet and exhaust valves is operated from the camshaft by a single rocker arm, the valves being connected by a T-head slide on which the end of the rocker rests. The slide is carried in contact with the rocker at all times by a coil spring in the center of its hollow stem. Each end of the slide carries an adjusting screw and locknut by which the clearance between the ends of the valve stem and slide can be adjusted. This clearance is 0.015 in. for both main inlet and exhaust valves. These pairs of valves are used instead of single large valves, as the small valves are much less apt to warp under the high temperatures to which they are exposed. This agrees with practice in high-powered aviation and motor-car engines.

The fuel-injection valve is located in the center of the head and is also operated by a rocker from the camshaft. The adjusting screw for this valve is set to leave 0.025 in. clearance when the valve is closed. All these clearances are those for a cold engine, and will be somewhat less as the engine warms up.

The valve timing, as regards the air inlet and the exhaust valves, is very close to an average four-cycle gasoline-engine valve timing, the figures being as follows:

Air intake opens 5 deg. before upper center.
Air intake closes 25 deg. to 30 deg. after lower center.
Exhaust opens 40 deg. before lower center.
Exhaust closes on top center.

The timing of the fuel injection valve is as follows:

Valve opens 7 deg. before upper center.
Valve closes 25 deg. after upper center.

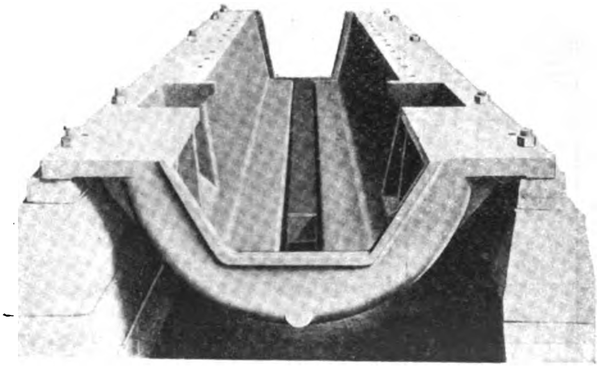
High-pressure-injection air flows all the time the injection valve is open. Fuel is injected, however, during part or all of this period, depending on the amount of power required from the engine. The amount of fuel is controlled by a centrifugal governor which limits the duration of the fuel pump suction as may be required to maintain the engine speed.

Cooling water is circulated through the jackets of the engine cylinders and air compressor by a four-cylinder plunger pump operating from the same small crankshaft which handles the oil circulating pump. This shaft is about the same size as would be used in large six-cylinder automobile engines, but looks extremely small by comparison with the rest of the powerplant.

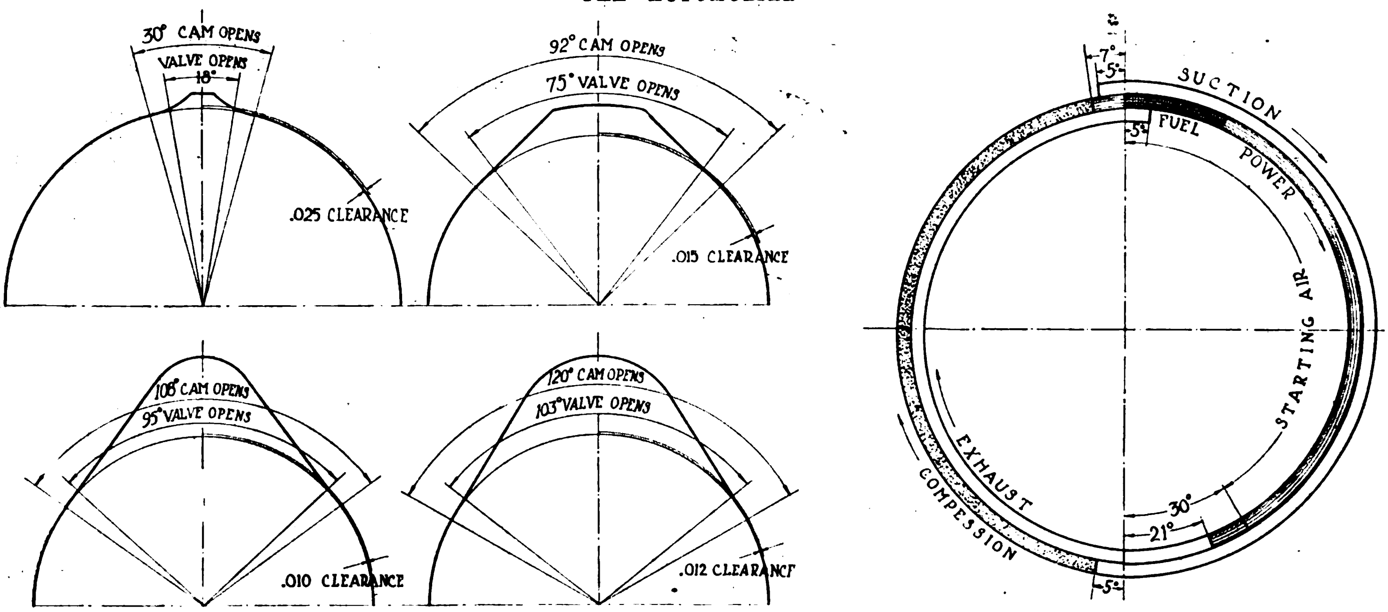
The oil circulating pump which provides lubrication for all the main bearings of the engine really consists of two single-cylinder pumps. The one driven from the end throw of the crankshaft operating the circulating water and lubricating oil pumps draws the oil from the sump in the lower half of the crankcase and forces it through a cooler and a strainer to a storage tank. The other single-cylinder pump draws the oil from this storage tank and forces it into the header, from which it is piped to the bearings, as described above. The discharge side of this pump is provided with an air chamber to insure constant pressure being carried on these bearings. The circulating water pump is of the four-cylinder type, and also has an air chamber on the discharge side to insure steady circulation of the water. The cylinders, pistons and stuffing-box glands are made of bronze to prevent injury by the water.

The supply of air for starting the engine is carried in steel air bottles, which are from 12 to 18 in. in diameter and 10 to 20 ft. long. These are stored wherever convenient on the ship and are connected by heavy brass tubing to a header running the full length of the engine. At the point where the pipe from the air bottles join this header is located a valve, which can be opened by pulling on a long handle. This admits the air to the header.

Each cylinder is connected to the header by means of a pipe in which is located a valve operated regularly by the camshaft. The end of this pipe connected to the cylinder is fitted with a special casting containing three valves. The first is a check valve to prevent the compression or power-stroke pressure from escaping from the cylinder. The second is an overload valve or safety valve, which is set to open if the pressure in the cylinder exceeds normal power-stroke pressure. A valve of this type is necessary to prevent damage to the cylinder or piston in case water or oil should accidentally collect in the cylinders. If this happened and the engine was started, the top of the piston would probably be broken out, as water or oil is practically non-compressible. The third valve in this casting is operated by a small handwheel and is opened only when it is desired to attach an



Oil pan of the Winton Diesel engine



Cams and cam setting on the Winton Diesel engine

indicator to determine the work being done by the cylinder.

Contrary to automotive practice, the exhaust is not fitted with a muffler close to the engine, but the air inlets for both air compressor and the main cylinders are carefully muffled. The air inlets to the main cylinders are connected to a large header, into which air is taken through a muffler at each end. This arrangement of drawing the air for the engine directly from the engine room has the decided advantage of constantly drawing fresh air into this room, thus insuring ventilation.

The thrust block at the rear of the engine has a unique feature, in that the thrust surfaces are lubricated under pressure from the engine oil pump. The thrust block consists of a short, heavy shaft flanged at both ends, one flange being bolted to the rear flange on the crankshaft. Turned integral with this shaft are a number of large collars between which the horseshoe-shaped thrust segments are mounted. Each of these segments is faced with babbitt on both sides and has a connection at the top to an oil lead from the pump. The babbitt facings are grooved so that the oil is distributed under pressure over the entire thrust surface. The segments are held in the proper position by nuts on heavy threaded shafts along each side of the thrust block. They are consequently readily adjustable for wear. They also are reversible, so that if the babbitt should wear or burn off one side a new bearing surface could be brought into operation by a few minutes' work.

Pressure Delivered by Air Compressor

(Test data)

High-pressure cylinder..	1050	1200	1175	1150	1225

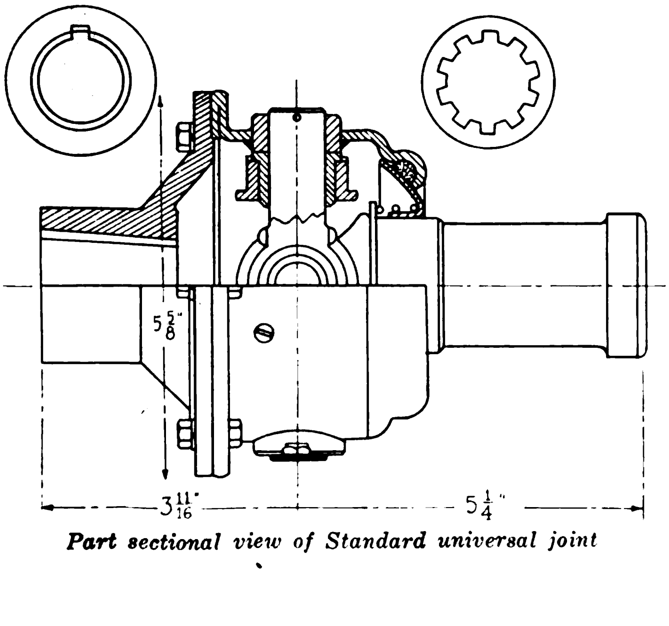
Camshaft runs half engine speed.

Oil and water pumps run two-sevenths engine speed.

New Standard Universal Joint

THE Universal Machine Co., Bowling Green, Ohio, has brought out a "4000 series" of its standard universal joint. This joint is only 5⅝ in. in diameter, and is said to be suitable for the largest 7-passenger car. It is of light design, weighing with flange only 9 lb.

The shell or casing is a stamping of ⅛-in. steel and has two hubs for the joint pins welded to it by the acetylene torch. Being made of such heavy material, there is no danger of the shell being dented by flying stones or through other causes. The yoke and hubs are made of drop forgings, and the pins and bushings are of carbonized steel hardened and ground. The joint is completely enclosed, use being made of an oil retainer in the form of a spherical segment, and of packing between it and the shell. Thus the oil is kept in and the dirt out. Suitable oil grooves are provided for all bearings. The joint itself is furnished completely assembled, and all the customer has to do upon its receipt is to secure the flange on the shaft and then bolt on the joint.



Part sectional view of Standard universal joint

This type of universal joint is furnished as a single joint, and also in double joints, assembled with either solid or tubular shafts, and equipped with a hardened, splined slip connection. This connection is provided with a grease-retaining felt and steel washer, and adjustable clamps.

ACCORDING to a recent address by Captain Guilliet, France in 1913 consumed 70,000 magnetos, of which 94 per cent were of German manufacture. Upon the outbreak of the war the magneto question became simply alarming. Both the aircraft and automobile industries developed rapidly and demanded a constantly growing number of magnetos. It was necessary to greatly increase the manufacture of these devices, by enlarging existing plants and establishing new ones, and the effort made was such that toward the end of the war France became the principal source of magnetos for the Allies.

Present Status of German Motor Industry

War Strain Has Worn Out Shop Equipment and Made Inroads on Supply of Skilled Labor—Country Stripped of Automobiles, But Materials Are Scarce

AS in other European countries involved in the world war, in Germany the automobile industry has greatly expanded during the past four years, but it has been engaged largely on products other than those which it turned out previously. During the war we had occasional brief notices regarding the activities of individual concerns and the prosperity of the industry as a whole. From this the conclusion might have been drawn that the German automobile industry was in a strong position and likely to become a formidable competitor in the world's markets, but a rather different view of the situation is taken in a lengthy report from United States Vice-Consul Robert L. Gray, Jr., of Lucerne, Switzerland, which has just been made public by the Bureau of Commerce.

According to this report, before the outbreak of the war Germany was equipped and able entirely to supply its own market for passenger cars. The number of automobile factories established in Germany was 38, all German owned and controlled. These factories were located in East Prussia, West Prussia, Rhineland, Bavaria, Baden, Wuertemberg, Saxony, and Hessen.

Present Scarcity of Trucks

The 43 automobile factories now existing in Germany—the war produced five new factories—have concentrated all their efforts to produce trucks for the army during the war. In 1917 and 1918 between 10,000 and 12,000 trucks—3-ton trucks of standard type—were produced. This represented the maximum output of production for one year. In all about 40,000 trucks have been manufactured during the period of the war. Four and more ton trucks have not been constructed to any great extent, because this type of truck was not used by the German Army. It was predicted and anticipated that in the event that peace came by the end of 1918 about 39,000 to 40,000 trucks would be returned by the army and placed at the disposition of the German people. Owing, however, to the terms of the armistice and to the rapid retreat of the German armies across the Rhine, hardly more than 9000 trucks were brought back, and these were all in very bad condition, almost unfit for further use. Again, it is worthy of note that the German construction of trucks is far behind what it should be. This is due to the lack of modern machinery, skilled workmen, and the hasty construction demanded by the military authorities. Also the lack of copper, tin, zinc, and especially of nickel and chrome, necessary for the production of the high-grade steel needed in truck construction, has greatly hindered the production of modern and durable cars.

Principal Truck Manufacturers in Germany

The following listed factories represent the principal automobile manufacturers in Germany who during the war manufactured only trucks. The figures quoted show roughly the maximum capacity of truck production for one month, reached during the period of the war:

	Trucks Per Month
Wuertemberg:	
Daimler, Stuttgart	100
Baden:	
Benz Gaggenau	100
Union, Mannheim	15
Bavaria:	
Saurer, Nuremberg	45
Faun, Ansbach	30
Prussia:	
N. A. G., Berlin	120
Bergmann, Berlin	40
Loeb, Berlin	40
Protos, Berlin	50
Hansa Lloyd, Bremen	100
Komnick, Elbing	60
Pomerania:	
Stoewer, Stettin	60
Westphalia:	
Duerrkopp (Bielefeld)	40
Rhine Province:	
Mannesmann } Daag }	90
Saxony:	
Vomag, Plauen	70
Horch	60
Hesse:	
Opel, Russelsheim	70
Adler, Frankfort	60
Total maximum production for one month	1,150

The remaining 24 factories are small concerns, engaged principally in the manufacture of motorcycles, motor side cars, munitions, and other war material.

Before the war the total production of trucks amounted to about 100 per month, Daimler, Benz-Gaggenau, and Hansa Lloyd being the principal manufacturers. During the war all the factories have been so enlarged that, together, they have been able to produce on an average of from 1000 to 1200 trucks per month. This includes the five new factories established and a number of the smaller concerns, not mentioned above, which produced from 2 to 10 trucks, respectively, per month.

Prices Nearly Doubled

During the war tractors were not made in Germany to any great extent. The Hansa Lloyd factory in Bremen manufactured tractors on a small scale, producing about 12 tractors per month. Though German manufacturers were engaged in developing a standard type of tractor they did not progress beyond the experimental stage.

It is hardly possible to give an exact idea of the prices the German manufacturer will be obliged to charge for passenger cars after peace has been signed. It is estimated that an increase of from 50 to 75 per cent is the least that can be expected. Prices of trucks advanced during the war about 75 to 100 per cent. Before the war the 3-ton truck, 45 to 55 horsepower (N. A. C. C. rating), sold at from 14,000 to 15,000 marks, without tires. The German Army at the beginning of 1918 paid 28,000 marks for a 3-ton truck, including steel tires.

From the commencement of the war all rubber tires, of whatever description, were confiscated by the German military authorities, and it was not long before the available supply was completely exhausted. In fact, the lack of tires in Germany became so serious that the German general staff was forced to limit the use of passenger cars needed for military purposes at the front. A large number of mechanical inventions calculated to replace the no longer obtainable pneumatic and solid rubber tire, especially those for use on trucks, were placed upon the market and tried out. However, no matter how good was the substitute produced, it never approached the point where it could be compared in

any way with the much-needed rubber tire, and in the end was cast aside as worthless. After the failure of the many invented substitutes to relieve the situation, all trucks were put on steel tires. This necessitated the reinforcement of the bearing parts of the trucks, at a considerable increase in the cost of construction. Even then the life of the truck was shortened, and it was not very long before the car was practically jolted to pieces or in a very dilapidated condition, making continual repairing necessary.

Synthetic Rubber Inadequate

From the first days of the war hope was placed in the ability of the German chemist to solve the problem of producing synthetic rubber and thus supply the urgent need of rubber required for all purposes in Germany. Especially was it hoped and confidently expected that it would not be long before synthetic rubber would be produced in quantities sufficient to enable the wholesale production of the greatly needed rubber tire. This dream was never realized. Although the German chemist did succeed in producing synthetic rubber, the product could not replace the natural rubber. This was due to the lack of elasticity, durability, and the high cost of production of the synthetic rubber. A large amount of this rubber was manufactured and mostly used for insulating purposes, in the construction of submarines, torpedo boats, electrical engines, etc., where it offered a good substitute for the natural rubber required. However, the synthetic rubber did not relieve or in any way affect the tire situation.

Large amounts of natural rubber belonging to German manufacturers are stored in neutal countries. With the signing of peace it is expected that this rubber will be released and the manufacture of solid rubber tires started immediately. Owing to the lack of cotton in Germany, it will be impossible for some time to come to manufacture pneumatic tires. In any event, the demand for rubber tires will be enormous, and Germany is not able to supply it.

Proposed Plans for Protection

On Nov. 18, 1918, the president of one of the largest automobile factories in Germany, and one of the most prominent men in the German automobile industry, addressed a meeting of about 75 representatives of all the automobile manufacturers in Germany. The meeting was private and no mention of the proceedings was made in the newspapers. In his speech he called special attention to the fact that the future standing and existence of the German automobile industry will depend entirely upon the ability to meet and cope with foreign competition. He proposed a consolidation of all the manufacturers, stating that every one must stand together and work for the common good of all, and that only by such united effort would they be able to succeed in meeting foreign competition. He also proposed to send carefully selected engineers, mechanics and automobile business men to the United States for the purpose of studying American methods of manufacture and organization, and to engage American engineers to come to Germany for the purpose of introducing American methods of manufacture and to modernize the German automobile industry. At the request of the assembled manufacturers, printed copies of this speech were sent to all members of the "Verein Deutscher Motor Fahrzeug Industrieller" (Society of German Automobile Manufacturers), Berlin, with the purpose of bringing before them the danger to be feared from foreign competition. What effect this speech will have is, as yet, unknown, but the fear is well founded and apparent, because Germany is not now, and will not for some time be, in a position to put this industry back upon the footing it occupied before the war.

Field for American Cars and Parts

In spite of the fact that Germany has lost the war, and in view of the facts above stated, there is no question that Germany will offer a good field for the introduction of American automobiles, trucks, tires, etc. In spite of the German Government's action in placing a luxury tax of 10 per cent upon all passenger cars, the number of prospective buyers is very large and continually increasing. The "Verein Deutscher Motor Fahrzeug Industrieller" is fighting against the 10 per cent luxury tax imposed by the Government, on the ground that it considers the automobile to be a necessity rather than a luxury. Likewise, all the leading business men and commercial newspapers are opposing the tax upon the same ground.

The war has also shown to Germany that the automobile is a valuable, quick and effective means of transportation, and its use in a strictly commercial sense is understood and fully appreciated by the German business man. In the larger cities in Germany, since the armistice, large companies with several millions of marks of capital have been formed for hauling and delivery purposes and for renting trucks.

Disposition of Army Trucks—Establishment of Truck Lines

Most of the 9000 to 10,000 trucks returned from the front have been purchased by the organizations above mentioned. Some of these companies are private, others have been subsidized by the State, and in the near future it may be expected that a great number will be established and controlled by the Government. In Bavaria an official declaration of the Minister of the Interior, department for traffic, has been issued, proposing to control the road traffic on trucks in the same manner as the railroads are controlled. In other words, truck lines will be established and run in connection with the railroads which are Government owned. This official monopoly, however, can only be ratified by the National Assembly. Before the war Bavaria was the leading German state operating and maintaining an autobus line, which replaced direct railroad connection between cities in the mountainous parts of Bavaria. It is now the intention to supplement this with a truck line for the freight traffic. This measure is viewed with great favor by all large commercial enterprises and individuals throughout Germany, who see in it a great advantage for the development and re-establishment of interstate commerce and trade after the war. Since the signing of the armistice large sums of public moneys have been appropriated by many provincial officials for the immediate reconstruction and improvement of the public highways. This work will give employment to thousands of discharged soldiers, and at the same time tend greatly to develop and improve the interstate commercial relations in many respects.

Condition of the German Railways

When consideration is given to the fact that the condition of the railroads in Germany is very bad, roadbeds in a neglected, run-down and extremely worn-out condition, rolling stock greatly depleted and in an almost ruinous state of repair, owing to the lack of proper lubricants and to the enormous demands made upon it during the four and a half years of war, it can readily be seen that the railroads must be supplemented by the automobile and trucks, especially with respect to freight traffic. The horse has almost disappeared from Germany.

There is no doubt that a great demand for motor cars of all kinds will arise throughout Germany. As conditions are now, it will be very hard, and in fact impossible, for Germany to manufacture an automobile or a motor truck at a price low enough to compete with American prices. Conditions have never been so favorable as now, in many respects, for the introduction of American automobiles and trucks.

Improper Selling Methods

Of all the foreign producers the American automobile manufacturer and exporter has been in the most disadvantageous position. Before the war several American firms exported motor cars to Germany, but no great success attended their efforts. This was due to a number of reasons, chief among which the following are worthy of notice: (1) The unskillful selection of the importer by the American producer. For instance, cars were sold to German importers who knew very little about the automobile business or who selected agents who were not capable to represent the car. (2) Lack of interest shown by importer in car after sale. When a car was sold the importer or his agents lost all interest in the buyer, and nothing was done, in many instances, to keep in touch with him or to look after the welfare of the car. This tended to create dissatisfaction among the buyers of American cars. (3) Lack of knowledge in many cases by

the importer and agents of the importer of market conditions. (4) Wrong methods employed to introduce American cars. This applied to advertising methods, lack of a well established and equipped repair shop, and choice of location and establishment of agencies.

The policy of many of the large automobile manufacturers in the United States of granting an agency or sole agency for a foreign country to a foreign importer upon the conditions that the importer should buy the car or a certain number of cars outright, f.o.b. New York, etc., and should have an established sales organization, be financially able to buy the cars outright, and guarantee to sell a certain number of cars per year, is not the proper method of procedure and will not result in the establishment of a permanent market or in the successful introduction of American cars to foreign markets. The moment the car is received by the importer it is alone in a strange country, duplicate parts are not readily to be had, the car is in the hands of mechanics who do not thoroughly understand its mechanism and construction, and are, therefore, not able to effect good repairs, and, in general, the foreign importers are not interested in the welfare of the car or in the satisfaction of the buyer after the sale.

Proper Methods for Establishment and Location of Agencies

It would be advisable and of great advantage to the American producer desiring to create a lasting market to establish his own agency in the prospective foreign territory. In the event that he desires to do this great care should be given to its establishment and organization and to the selection and location of the principal office and subagencies. This part, especially with respect to the selling end, should be placed in the hands of a man who is thoroughly familiar with the country, people, language, methods of procedure, and organization employed in this instance by the German automobile industry, and who has large and influential connections in the country and good experience in the automobile business. This is especially necessary for the selection of sales agents.

With respect to location, Berlin and Munich are the two principal cities to be considered. Munich more so than Berlin, because the latter city and Prussia, in general, have undoubtedly lost during the war a great deal of former influence and prestige. In the event that German Austria, with Vienna as the principal city, decides to throw in its lot with Germany, Munich would be the best choice for the head office.

In connection with an established agency, it is of great importance to have a well-equipped repair shop, including a large stock of duplicate parts. There is no doubt that a prospective customer would be largely influenced by the possibility of having his car repaired by the original firm and of being able to secure duplicate parts at once. The establishment and maintenance of a well-equipped repair shop will support the sale of the car by at least 50 per cent.

It is advisable to say a few words regarding the methods of advertising as carried out in Germany with respect to the automobile. The German method of advertising cannot be taken as an example of the right method, because it does not bring before the public a proper and strong conception of the idea involved. In any event, the German does not attach the importance to advertising the American producer does. While the American methods of advertising, as carried out in Germany, have been excellent in many respects, they have not been in such form and style as to attract especially or appeal to the German conception of things. Also mistakes have been made in the manner of placing the advertisements before the public and in the selection of the proper papers to carry them.

German Sales Methods

Until shortly before the war all German automobile manufacturers were selling their cars on a commission basis. A certain specified territory was allotted to a commission agent for a number of years as stipulated by contract. The agent was required to sell a certain number of cars per year or else forfeit his contract, or placed in a position which eventually necessitated him to relinquish his agency in the event he could not dispose of the number of cars he was under contract to sell. Every car was sold at a fixed price set by the manufacturer. In case the agent sold this car at a lower or higher price he forfeited his contract. The agent's commission was included in this fixed price. When, toward the end of the year, an agent saw that he had not sold his required number of cars and would not be able to do so before the end of the year, he immediately set to work to sell the car at a price much lower than the set factory price. This reduction sometimes involved the sacrifice of his entire commission on the sale of the car at the normal price, and in some instances, where the situation was desperate, the agent sold the car at a price which not only involved his entire commission but required him to make up the price at which the car was sold to him by the factory. Of course, the buyer of the car paid the set and fixed factory price to the agent, however, with the understanding, made beforehand, that the agent would make him a present, before or after the purchase, of 1000 marks, or of a horse, gold cigarette case, diamond ring, etc., according to the terms of the discount offered by the agent in order to effect the sale of the car. Again, inasmuch as the agent was naturally controlling the market in his allotted territory for the sale of the car represented, it was not long before he was demanding higher commissions and a better contract with the producer. If the agent's demands were not granted he, in many cases, simply took another representation at the expiration of his contract with the manufacturer and did everything possible to influence the market against the car formerly represented by him, and in this he generally succeeded. In fact, conditions were such that the agents were, to a great extent, controlling the producers. In order to protect their interests the producers formed a combination to bring pressure to bear against the agents and their methods, and to prevent what threatened shortly to be the complete control of the producer by the agents. This organization of the producers was known as the "Verein Deutscher Motor Fahrzeug Industrieller" (Society of German Automobile Manufacturers).

This resulted in the agents combining and forming an organization known as the "Deutscher Automobil Haendler Verband" (Union of German Automobile Agents), to counteract the combination formed by the producers. This resulted in the producers, starting with the larger manufacturers, installing their own agencies in all of the large cities in Germany and elsewhere, as soon as the contracts with their former agents had terminated. The smaller companies, in a great many cases, soon followed suit. In all the large cities in Germany there will now be found branches of the principal manufacturers with offices and exhibitions. As this system was introduced only shortly before the outbreak of the war, it is impossible to give statistics of comparison of a reliable nature. However, the results obtained so far have been extremely satisfactory.

INDUSTRIAL GOODWILL

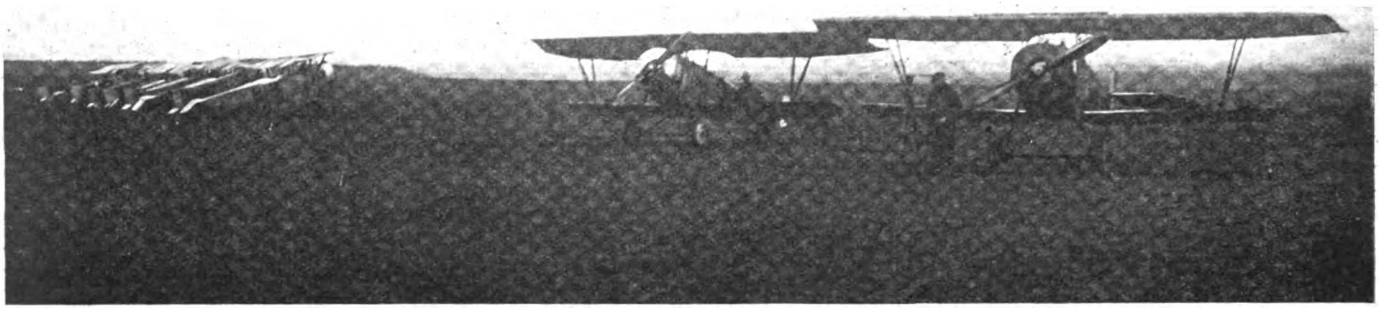
INDUSTRIAL GOODWILL. By John R. Commons, University of Wisconsin. New York: McGraw-Hill Book Co., Inc. Price, $2.

This book deals with the labor question from the industrial standpoint. It deals with the commodity theory of labor, with the machinery theory of labor, with the position of goodwill as a labor matter, the concern of the public, the question of democracy, the solidarity of labor, education, health, insurance and other similar matters.

The book presents cases for the various subjects and the conclusions in a very simple, practical form, and it contains a great deal of information which it would be well for all men connected with the handling of labor to have available and to understand.

It does not attempt to deal with the organization question as such, nor does it bring in the political and social side to any great extent.

As it stands, it cannot be considered as a complete exposition of the relations between employer and employee or of the deficiencies of the present methods of organization and outlook. It attempts to cover only certain specific branches of the subject and in respect to those branches the information is accurate and valuable, the material is well presented and readable and should prove of interest to those who have either control or supervision of labor.—HARRY TIPPER.



Nieuport airplanes supplied by the French to the American army

The Airplane Supply System of the American Army in France—II

The Advance Depots—Handling 18 Tons of Materials a Day for Seven Months at One of Them—The Balloon Supply Service—How Automobile Equipment Was Provided

By W. F. Bradley

IN any system of supply, whether it be civil or military, it is rarely sound policy to ship direct from the producer to the consumer. Under war conditions such a policy would be suicidal. The men who are doing the actual fighting must be relieved of all responsibility connected with the furnishing of supplies. The infantryman, whether he is hard in pursuit of the enemy or whether falling back in a stubborn fight, expects to be provided at all times and under all conditions with the two essentials, food and ammunition. The men who fight in the air need the same essentials, but in addition they call for a host of detail and highly specialized articles, the loss of any one of which might spell disaster.

An aviation squadron is the most mobile unit under the sun. Almost at a moment's notice the machines can be prepared for flight, and after an hour in the air they can be at some new location 100 miles from their original base. By reason of automobile transportation their squadron equipment can be brought to them at such a new center within 24 hours. Such changes may come two or three times in one week, or they may not have to be made more than once in several months. In war it is necessary to be prepared for all emergencies.

Because of these constantly varying circumstances, it is necessary for the big supply centers in the rear to furnish material to advance depots, which in turn distribute to the squadrons in the field. The Air Service of the American Expeditionary Force established its most important advanced depot at Colombey-les-Belles, 11 miles south of Toul, at which point there were 90 officers and 2000 enlisted men receiving airplane motors, propellers, spares, hardware, instruments, clothing, etc., and distributing them, as requisitioned, to the squadrons in the field. In other words, this was a retail store, but a retail establishment which did business on a big scale, for during the month of September alone this depot handled 2595 requisitions, each requisition comprising from 40 to 50 articles. The regular clients of the depot in the month of October, 1918, were 23 headquarters groups, 16 observation squadrons, 4 bombardment squadrons, 20 pursuit squadrons, 12 park squadrons, 8 photographic sections, and 22 balloon companies.

What Was Done at Colombey

The standard requirements of an air force in the field are infinitely varied. Some of the big lines are gasoline and lubricating oil. Thus, while it was in active operation, from April 1 to Nov. 11, the depot at Colombey-les-Belles sent out 206,000 gal. of transportation gasoline, 280,000 gal. of aviation gasoline, 167 gal. of special fighting gas, more than 47,000 gal. of castor oil, and about the same quantity of Mobiloil BB. At the other end of the line were the small articles: altimeters, speed indicators, engine parts, special aviators' clothing, which do not look big in statistics, but which are absolutely essential to successful operation.

In addition to furnishing these regular consumable stores, Colombey was the receiving center for foreign airplanes despatched from Orly and American airplanes sent out of Romorantin. In nearly all cases the ferry

pilots landed the machines at this point, from which they were taken in a single short flight to the squadrons located in the immediate vicinity of the line. These new machines sent out to make up losses, or to form new squadrons, were replaced by wrecked or partly wrecked planes in an almost equal number. Colombey received these crashes in all sorts of conditions. Some were subjects for the junk pile, in which case whatever accessories could be saved were taken off and put into storage. Others were capable of rebuilding and of going into service again. In the month of August, when the battle was at its height, the airplane repair depot at Colombey received 175 crashed planes. Of this number it was possible to repair 52 and return them to active service. Up to the signing of the armistice a total of 237 crashed planes had been repaired and sent back into the fight.

Advance Depot No. 1

Ninety miles from Colombey was another depot, known as Advanced Depot No. 1, at Is-sur-Tille, where, with a storage space of 70,000 sq. ft., clothing and airplane parts, machinery and tools were handled and sent out to 40 different units of the A. E. F. This was a quick-action center, for of the requisitions received 90 per cent were executed and the goods delivered within 24 hours. For seven months this depot handled 18 tons of material a day. At Vinets, in the Zone of Advance, sufficiently far up for a short single flight to the front, was another spare parts depot and ferry station. Further back, at Chatenay, on the mail railroad line from Paris to Chaumont, still another depot got into its full stride only a short time before the armistice came.

Special Section of Balloon Companies

While a part of the Air Service, the balloon companies form a specialized section with altogether special material. Working usually in conjunction with the heavy artillery, their captive balloons have to be in the air whenever weather conditions are favorable for observation, and they have to be capable of following every movement of the guns. Their entire equipment is automobile transported, and consists of special four-wheel drive trucks, on the platform of which there is fitted an auxiliary gasoline engine and winch for controlling the height and movements of the balloon.

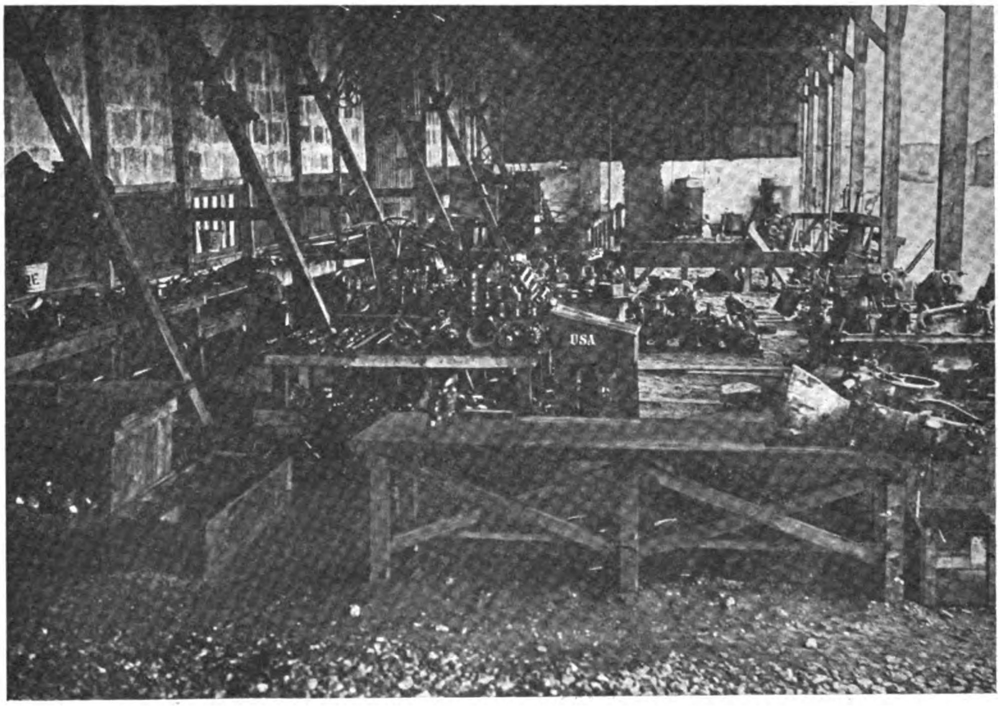
These trucks, with power transmitted to all four wheels, are capable of traveling over any kind of country and taking up any position that the artillery may designate as necessary for carrying out effective observations. In addition to these, there are special balloon tenders, also capable of traveling over any kind of country, and made use of specifically for carrying supplies to the winch-trucks and the balloons. Next in line are more standard types of trucks for carrying the stores and baggage.

At the time of the armistice there had been got together equipment to furnish 50 balloon companies and keep them in operation for four months. About 75 per cent of this material had been supplied by the French and 25 per cent came from America. Because of shipping difficulties the French had been appealed to for winch-trucks and had furnished 50 special Latil trucks, fitted with the Cachot power winch, as used by the French army. In addition to these a large number of special 4-ton trucks had been turned over by the French to the balloon companies at a time when shipment of similar material could not be obtained from America.

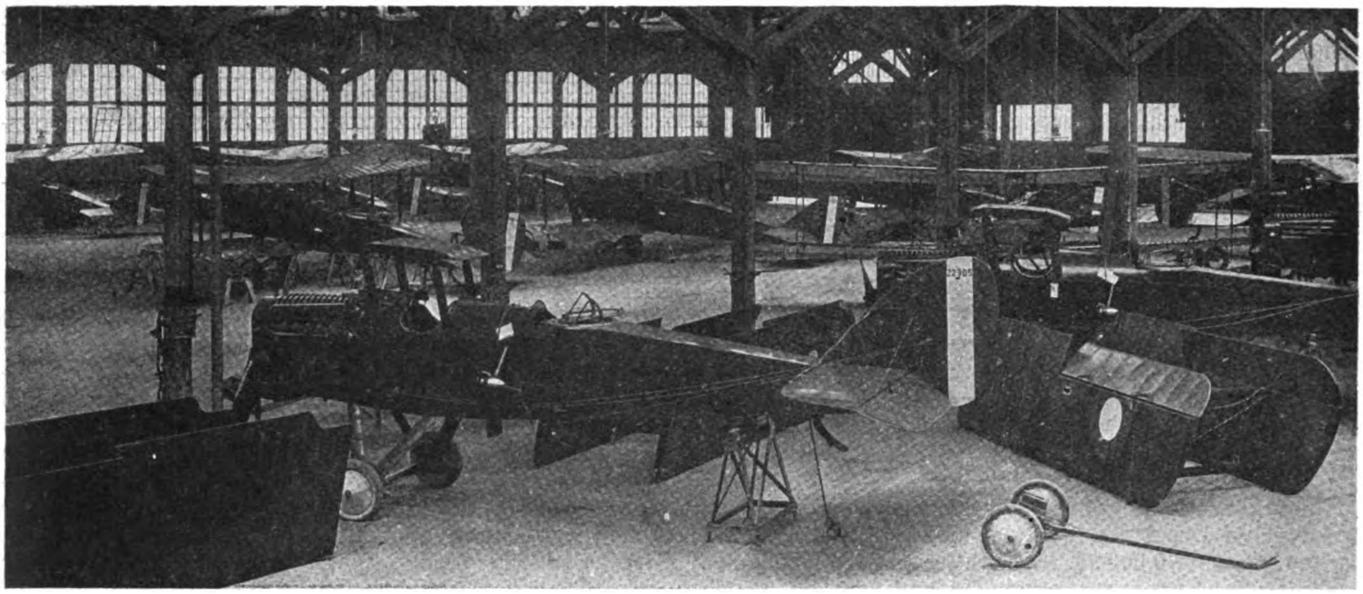
Balloon Companies Had Separate Supply Depot

Because of the special nature of its requirements, the balloon companies had their own main supply depot, independently of the airplane service. It was one of the accidents of war that this depot should have been erected by Germans and used as a factory by the Continental Tire Company, of Hanover, until August, 1914. The German personnel escaped before the storm broke, the French took possession of the factory, enlarged it, and on America coming into the fight turned it over to the Air Service as a balloon depot. Before the fighting stopped this one-time German factory had become the biggest hydrogen gas producing center in the world, with an output of 500,000 cu. ft. per day. During the active period this depot sent out 1650 tons of special balloon material.

It is one of the features of the Air Service that while regular work is going forward, something new is always in preparation. The biggest scheme that the American Air Service was working on as a surprise for the Boche was the organization of night bombardment groups. Had the war continued a few weeks longer these machines would have been in commission and making nightly trips over the German lines with deadly effect. The planes were of the Handley-Page type, built in America, but sent to the Handley-Page factory in England for equipment. On Nov. 11 most of the parts were in hand for about a dozen planes, and the remainder were following up at a rapid rate. These planes, formed into squadrons of 10, would have been flown from England to the field at Orly,



Air service automobile repair and salvage shops at Romorantin



DH-4 airplanes in the assembly shops at Romorantin on the day of the armistice

where they would have received their equipment and picked up their automobile transportation sent out from Romorantin. Supplied with this, the squadrons would have flown to the depot at Vinets, and then proceeded to the special airdromes already prepared for them at various points along the front.

Providing Automobile Equipment

No air force can operate for a single day without automobile transportation. Even in the preliminary stage, which consists of securing supplies, clearing the ground and erecting buildings, the first request made is for trucks and passenger cars. When the preliminary mission came over to map out the ground, in the early summer of 1917, its first requisition, if there had been anybody to receive a requisition, would have been for automobiles. But the French supplied the need in both machines and drivers until the service had grown so much that it was intimated other arrangements should be made. There were plenty of automobiles in America, but the trouble then, as for a long time afterward, was in getting them through the ports and across the Atlantic. Automobiles being required too urgently to admit of delay, and Italy being in a position to make immediate deliveries, an officer was sent to that country with instructions to bring machines back with him by road, which order was carried out in less than a week.

The Air Service had the foresight to see that in the scramble for shipping space the delivery of automobiles from America would be unsatisfactory for a long time, and that some of the special types of vehicles which had never been produced in the United States would be unavailable for many months. In consequence the wise decision was taken to secure available European material, most of it supplied by Italy, at the beginning of the movement. It followed, as a result of this policy, that when the really active period began in the spring of 1918 the Air Service was the only section of the American Army adequately provided with automobile transportation. This material had been selected on the experience of the French and British armies in France, and consisted in addition to the ordinary touring cars and motorcycles, common to the entire army, of special light and heavy aviation trucks, trailers, machine shop trucks, etc.

When the work was at the height of its prosperity, a general order was issued calling for the pooling of all automobile transportation. Under this order the Air Service had to be sacrificed for the benefit of the American Expeditionary Forces as a whole. Those in authority, also, seemed to be of the opinion that the Air Service should not be mobile and that it did not require more than a fraction of the material provided for in the tables of organization. The Air Service consequently turned over about 2000 new and unused vehicles, and from that time on became dependent on the Motor Transport Corps for its transportation.

In this great task of supplying the American Air Service in France there were employed 3000 officers and 20,000 enlisted men. In the Paris district alone, including Orly, there were 7000 officers and men. There was never a single moment when the job was easy, and there were times when it was so difficult and complicated as to discourage all but the stoutest. In the Supply Section they had a motto, "It can't be done, but here it is," and probably nothing could better describe the general attitude and conditions of the organization.

The Men Who Did It

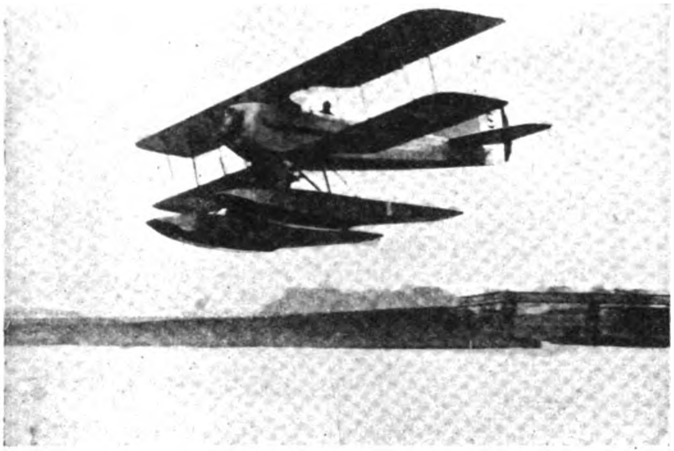
The men who did effective work on this big job are many. Right at the beginning Colonel Bolling came out with a few experts to pave the way. Active results did not immediately follow. The death of the Colonel early in 1918 was one of the many tragedies of the war. While on a visit to the British Front, Colonel Bolling was surprised by the advancing Germans and his automobile put out of commission by machine gun fire. Taking refuge in a shell hole, in company with his chauffeur, he determined to make a stand, although the only weapon the two men possessed was a service revolver. The end of this unequal fight was that Colonel Bolling was left dead on the field and his chauffeur led captive into Germany.

From near the end of 1917 to early 1918 General Foulois, one of the most experienced aviators in the Service, was Chief of Air Service in France, until he took charge of Air Service operations at the Front, when he was afterward succeeded by Brigadier General William Mitchell. In the spring of 1918, with Germany seriously threatening and the Allies calling on America to make a mighty effort, it became apparent that the American Air Service could only meet the call by close co-operation with the French.

Major-General Patrick, who conducted operations as Chief of Air Service in France until the close of opera-

tions, was made Chief of Air Service upon the relief of General Foulois in early 1918. Colonel Halsey Dunwoody was assigned to duty in April, 1918, by General Foulois, then Chief of Air Service, to organize the Air Service Supply and to negotiate with the foreign governments in order to obtain material to create the Air Service and maintain it until the necessary material should have come from America.

Colonel Dunwoody assumed this duty before the Air Service Supply Section began its operations and held the position from that time until the termination of the war. He was responsible to General Foulois and later to General Patrick, not only for negotiations and supply proper, but also for production, maintenance, transportation, salvage and the operations of all depots, also the big centers of Romorantin, Orly and the ports organizations.



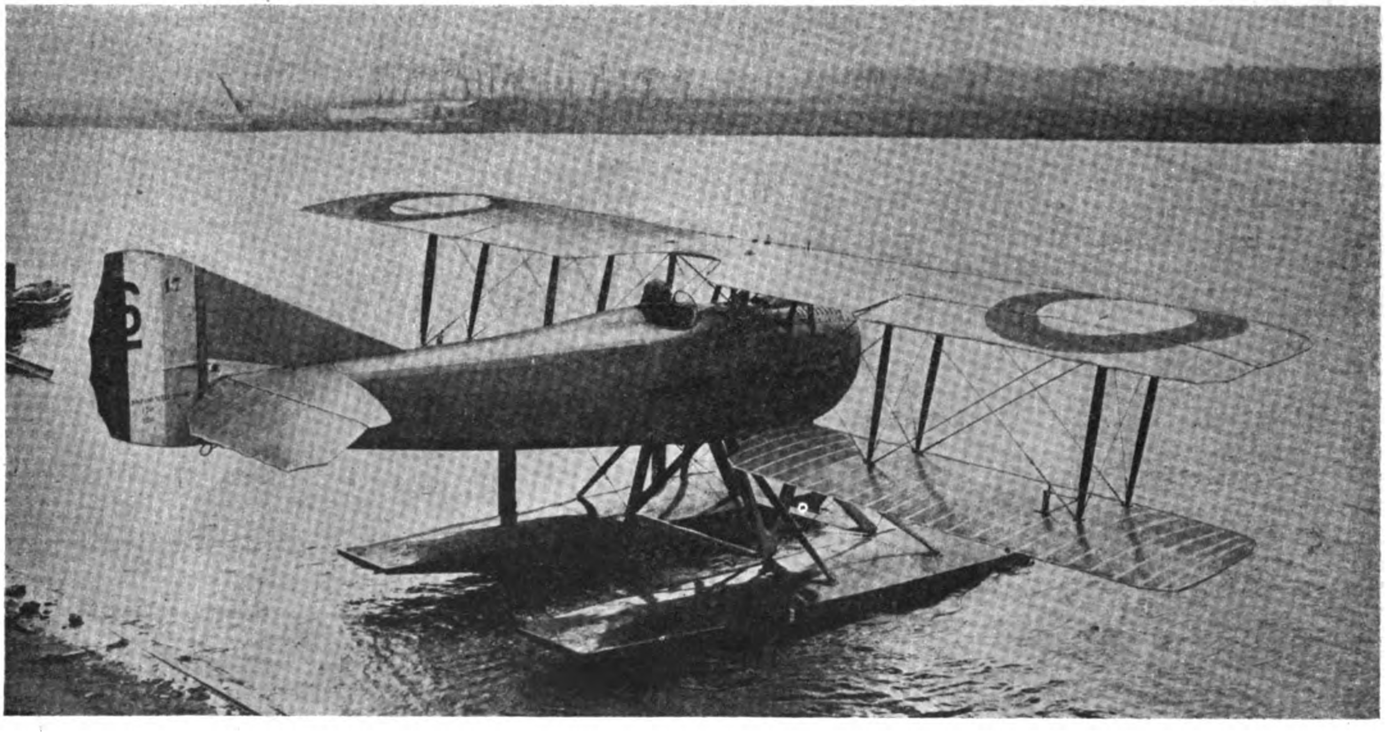
Spad hydroairplane in flight

It is difficult to give adequate appreciation of the magnitude of this work. It must be borne in mind that the conception, the building and the maintenance had to go hand in hand throughout the period of the great effort against Germany. It was only by resolutely attacking and overcoming all obstacles that this giant business enterprise was perfected until it was in a position to meet the material program of the Air Service needs in France.

New Flying Speed Indicator

THE anemotachometer is a new important instrument for aircraft, for measuring the actual or relative speed of the flying machine. It is made in the form of a cross, each arm of which carries a cup-shaped impeller which the wind drives. The rotation of the wind-driven impeller on its central spindle actuates a pendulum movement, the strokes of which are transmitted to the indicating dial. One of the greatest advantages of this instrument is that its action is always positive and is not affected by the density of the air through which the aeroplane is passing and, further, that the anemotachometer comes into action immediately the machine starts.

As this instrument has to be near the driver's seat, in large flying machines the same four-cup cruciform anemotachometer is used, but in this case the control is electrical and the flying speed is given by the voltmeter above the pilot's seat. This instrument has a second valuable use in that from it the pilot can judge the curvature of his course. Owing to the number of motors which are now included in the design of one airplane, steering has become very difficult, and it is often impossible for the pilot to know in foggy weather whether he is steering in a curve or straight forward. If two anemotachometers electrically connected to a central voltmeter are placed toward the extremity of each wing of the airplane, then the indications of both instruments will be the same if the machine is flying straight, but if flying in a curve the instrument on the inner or shorter radius of the curve will register a slower speed than the one on the outer radius. From the difference between these indicated speeds, the curvature can be seen from a properly prepared chart on the indicator dial.

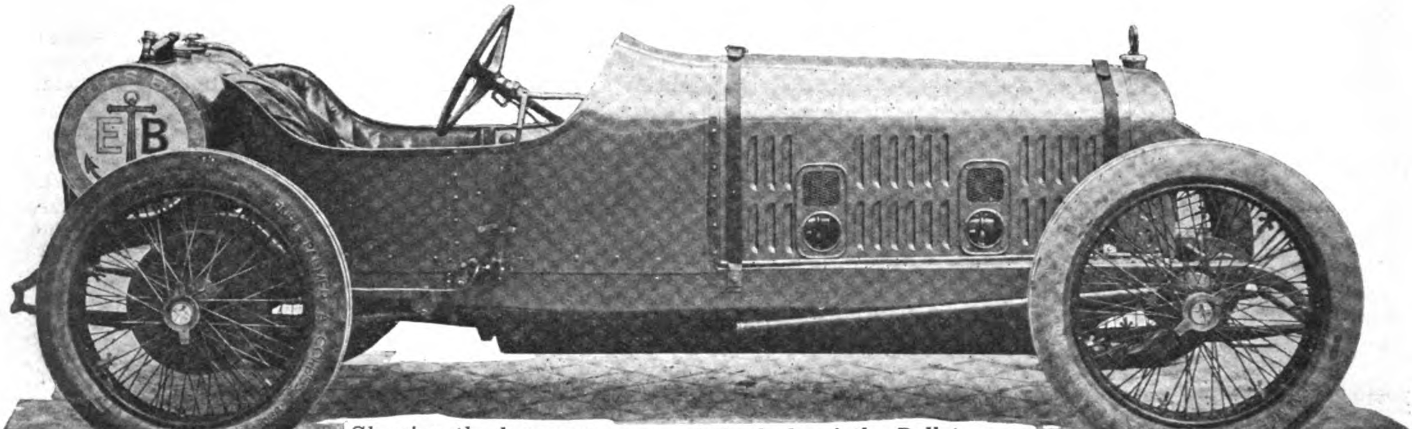


Spad hydroairplane constructed in France. It is interesting in that it is virtually one of the famous Spad fighting planes mounted on pontoons. Note the short span, the absence of wing tip floats and the large aileron surfaces in upper wing only. The control rods for the aileron are carried inside the lower wing and operate the surfaces through a bell crank and rod at the back of the outer rear strut. The engine is a 200-hp. Hispano-Suiza

Ballot Racing Cars
Built for Indianapolis Track Conditions

Designed and Produced in 102 Days—Eight-Cylinder Vertical Engine with Built-Up Ball-Bearing Crankshaft—Large Wheels and Low Body

By W. F. Bradley



Showing the low appearance of the body of the Ballot racer, which is mounted on underslung springs

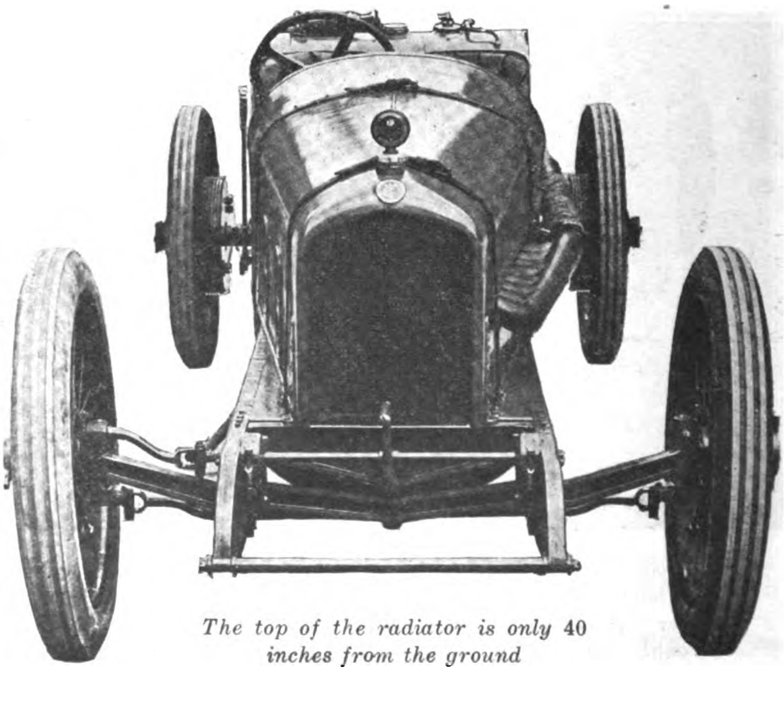
PARIS, April 24—The four special Ballot cars entered for the Indianapolis race are absolutely new productions, built in Paris entirely at the Ballot establishment with Indianapolis track conditions especially in view. They were constructed in record-breaking time, being designed and produced in 102 days.

They have eight vertical cylinders in line, consisting of two castings of four. The bore and stroke is 74 x 140 mm. (2.9 by 5.5 in.). There are four valves per cylinder mounted in the head and operated by means of two camshafts driven by a train of gears contained within an aluminum housing at the front of the engine. The crankshaft is built up in four parts and is carried in ball bearings. I-section connecting rods and aluminum pistons are employed. The engines have a single plug per cylinder and only one magneto. There are two Claudel carbureters per engine.

The engine, clutch and gearbox are mounted on a subframe which is attached to the main frame by three-point suspension, so that there is no possible misalignment no matter how much the main frame members are twisted. There are four speeds and reverse. Drive is taken through the springs, which are of the semi-elliptic underslung type. The front springs are also underslung. The rear axle is full floating type, composed of two forged axle tubes and a central aluminum housing. The center of gravity of these cars is exceptionally low. With 880 x 120 mm. wheels and tires (practically 34 in.) the top of the radiator is only 40 in. from the ground. No special attempt has been made at streamlining and the cars will be run without a tail.

While exact figures regarding speed are not available for publication, it may be stated that these cars are the fastest 300 cu. in. mounts ever produced in France. They will be particularly dangerous in track work by reason of their rapid acceleration. All previous French cars sent to Indianapolis have been road racing machines built for the long straightaway stretches of French roads.

When the Ballot Company undertook the construction



The top of the radiator is only 40 inches from the ground

of these machines it was guided by the experience of René Thomas, who decided that Indianapolis called for a very low center of gravity, good balance and suspension to reduce tire wear, and exceptionally rapid pick-up. The wheel diameters are the biggest ever used on the Indianapolis track, and the cars are the lowest ever seen in America. The final gear ratio has been laid out with the nature of the track in view. There appears to be no doubt that these cars will be able to tackle the four turns per lap at a much higher speed than any of the others, and it is believed that their powerful pick-up on coming out of the turns will give them an exceptionally high speed on the two straight stretches.

Details of BALLOT RACING CARS

No. of cylinders	Eight
Arr'g't of cylinders	In line
Bore and stroke	2.9 x 5.5 in.
Crankshaft	Four-piece, ball bearing
Valves	Four per cyl.
Camshafts	Two overhead
Ignition	Single, magneto
Carbureters	Two Claudel
Gearbox	4-speed and reverse
Springs	Underslung semi-elliptic
Wheels	880 x 120 mm.

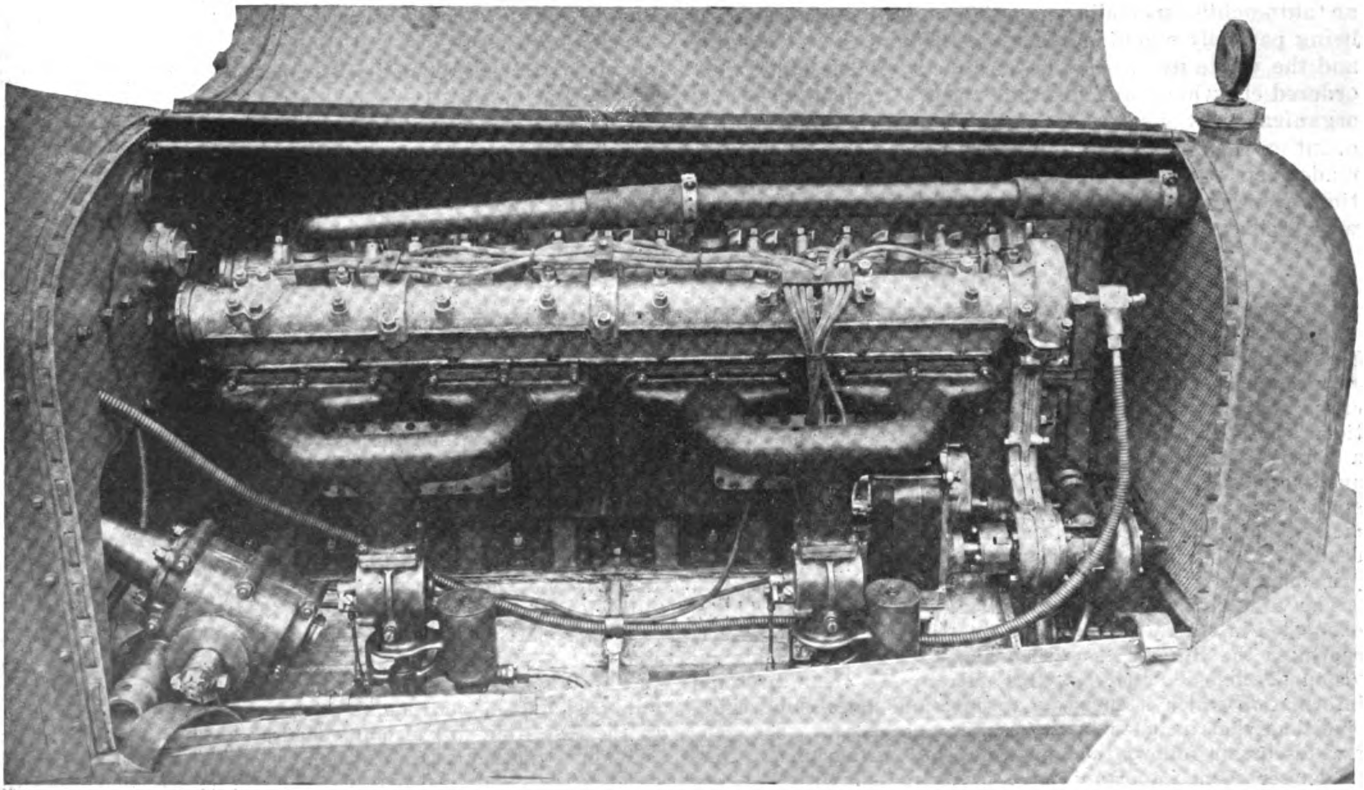
Designed and Produced in 102 Days

The building of these four cars constitutes a record in the history of the automobile industry of France, if not of the world. Immediately after the armistice was signed, the writer approached the leading European automobile manufacturers with a view to securing their participation in the Indianapolis race. Some of these firms had decided to race after the war; two of them had cars built; one had an engine partly completed, and one had drawings well in hand. After due consideration, all these firms decided that in view of the very unsettled state of the industry it was a material impossibility to build racing cars between Nov. 11, 1918, and the end of April, 1919, the date on which shipment would have to be made for Indianapolis. In fact, the French makers signed an agreement among themselves not to participate in racing during 1919.

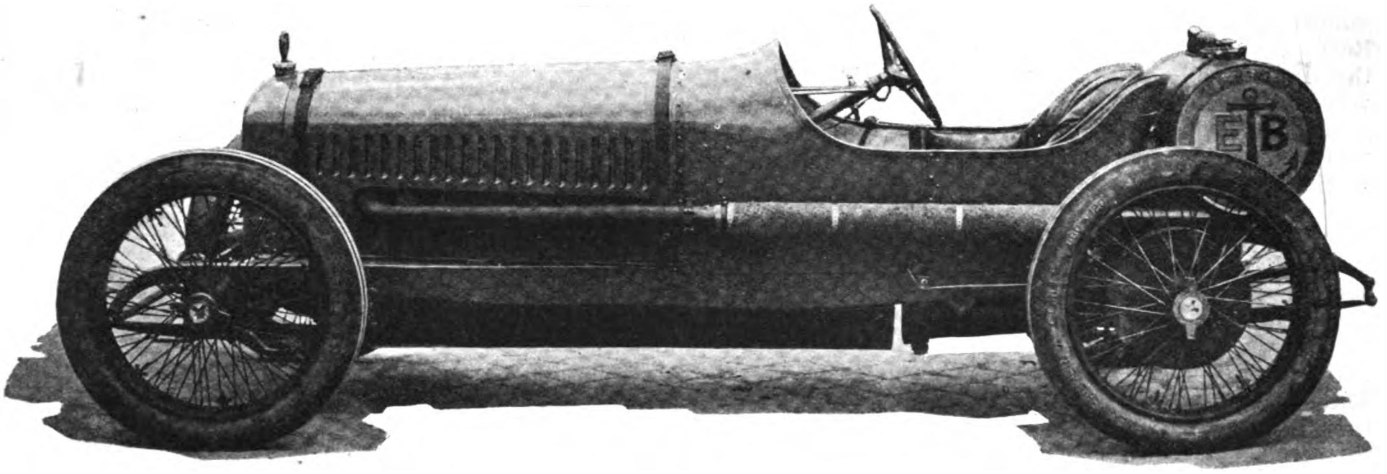
After the attempt to get special cars out of the European factories had failed, the subject was brought before the Ballot Company, one of the largest firms in France specializing in automobile engines. On the morning of Dec. 24 Mr. Ballot announced that he would build a set of cars for Indianapolis, and on the evening of the same day a contract had been signed between Ballot and René Thomas whereby the latter entered the company as head of the racing team.

In order to reach Indianapolis on time it was necessary to ship the cars from Paris not later than April 26. This meant that there were 120 clear days, including Sundays and holidays, in which to design, build, assemble, test and pack a set of special racing cars. No set of racing cars had ever previously been built in France in less than twelve months, and even this time was considered short. It must be remembered that although the fighting was over, a state of war existed in France, labor was scarce, material hard to procure, and transportation in an impossible condition.

To secure secrecy, it was decided that the drawing office should be far removed from the Ballot factory. Dec. 25 and 26 were spent in looking for an establishment. It was discovered 12 miles from the Ballot factory in a house



The engine used on the Ballot racing car has its eight cylinders arranged in line in two blocks of four. It is equipped with two Claudel carbureters and a single magneto. Two overhead camshafts operate the valves



One of the four Ballot racers entered for Indianapolis

and courtyard which had been abandoned by a German firm on the outbreak of the war.

On Dec. 26 Mr. Ballot called in one of his best engineers and three of his most skilled draftsmen and informed them that he wished them to disappear immediately from both home and factory and to remain absent for two months. The same day these men loaded drawing office equipment, a stove, bedding, coal, and gasoline aboard a closed truck and went off to an unknown destination. On Dec. 27 the first work was done in the secret drawing office of the Ballot racing establishment. Before making this change the men had been working full time; during the first month each draftsman nearly tripled his working hours. No man left the building except to take meals.

The first real difficulties were experienced when crankshafts were ordered. The first five, forged by one of the best firms in France, could only be delivered by sending an automobile specially on a 300-mile journey. After being partially machined they were found to be defective and the whole five had to be scrapped. Three more were ordered elsewhere, and also had to be scrapped. The disorganization was so great in the French factories, consequent on the change from a war to peace basis, that parts made from bar steel supposed to have the same specifications were found to vary 100 per cent. At this time the work fell behind the close schedule which had been laid out and the advisability of abandoning the scheme was considered.

Finally it was decided that the Ballot Company should forge and heat-treat its own shafts, and in view of the difficulties which had been met, a test piece was taken from every individual bar, and every bolt and nut which went into the car was subjected to the Brinell test.

On April 7 the first Ballot racing car was run in the yard, after the workmen had left. It had been designed and produced in 102 days, including Sundays. Although everything had been built in the Ballot shops, with the exception of carbureters, magnetos and wheels, the secret had been so well guarded that nobody outside the racing department knew what was going on. On April 11 the first car was approved by the French Government inspector, and on the following day René Thomas went on the road for five days' test.

Shipping space was secured aboard the French liner Savoie, sailing from Havre on April 26, but the railroad service between Paris and the port was so unreliable that on April 24 the boxed cars were loaded on automobile trucks and sent to Havre by road. To provide against any possibility of a breakdown at the last moment, a reserve truck followed behind with a couple of skilled mechanics in attendance. Arrangements were made whereby, on reaching New York, the cars should be unloaded from the steamer and carried to Indianapolis as personal baggage.

Testing Motor Gasoline

IN May, 1917, the Bureau of Mines, Department of the Interior, issued Technical Paper 166, "Motor Gasoline Properties, Laboratory Methods of Testing, Practical Specifications," by E. W. Dean. This paper was prepared because of a general desire for information relative to the properties and methods of analyzing gasoline. The Bureau of Mines studied the problem and prepared a paper discussing the methods of production and essential properties of gasoline, describing laboratory methods of analysis and outlining the principles upon which gasoline specifications should be based.

The first edition of this technical paper (No. 166) was exhausted in the fall of 1918, and instead of merely having it reprinted the Bureau has issued a revised edition. This revision (Technical Paper No. 214), also by Mr. Dean, presents information which is more up to date and more comprehensive than that included in the earlier publication. The general discussion follows the same lines, but certain phases that no longer seem important have been treated with less detail, and considerable additional information obtained during the last two years has been added. The recommendations made in the earlier publication regarding analytical methods and systems of specifications have been changed only in a few minor details, but the method of presentation has been changed in order to make the information more usable.

Technical Paper No. 214 includes a general description of the properties, methods of production and methods of testing gasoline. The practical interpretation of results of tests is discussed in some detail. The problem of writing specifications for gasoline is treated and specific recommendations are made regarding the limitations which are believed to be important. Figures specifying any particular grade of gasoline have not, however, been included, as it is believed by the Bureau that no single general specification is desirable.

The properties and methods used for the analysis of gasoline are described in detail. Chief emphasis is laid upon the tests of greatest importance, such as the distillation analysis, but in addition a description is included of most of the tests that are recommended or used either by the Bureau or by other organizations. Convenient forms for recording the results of analysis of gasoline are shown and the table is included for transforming Centigrade temperatures into Fahrenheit equivalents.

Copies of this publication may be obtained by addressing the Director of the Bureau of Mines, Washington, D. C.

Tractor Hitch Problem Fundamentally Mathematical

Simple Laws of Dynamics Apply—Most Hitch Problems Can Be Worked Out Graphically

THE tractor hitch problem is readily capable of mathematical analysis. Many of the matters which have been debated from all sorts of angles are clearly open to geometric proof or can readily be solved by graphic statics. While, in general, it is always best to get away from the purely mathematical and to bring home in other ways the advantages and disadvantages of certain types of design, the matter of relation of the tractor to its load through the medium of the drawbar connection cannot logically be discussed in any other way.

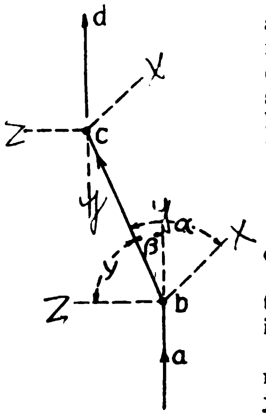


Fig 1

The propelling force of the tractor, the weight of the tractor, the character and form of the load or trailer, whether it be plow, road drag, or any other form of load, and the other fundamental factors are all measurable quantities which determine the effect that the hitch has upon the tractor and the implement.

This being the case, a purely mathematical analysis of the matter is well worth while. E. A. White of the University of Illinois has gone into the matter from this standpoint and the following is a digest and re-arrangement of the facts presented by him in a recent paper.

It is a well-known principle of mechanics that one force or one force and a couple may be found which will produce the same effect as a number of forces. In addition to this due consideration must be given to Newton's Third Law, viz., "Action and reaction are equal and opposite." A proper application of these universally accepted laws together with other well-known principles of statics furnishes the keys to a thorough understanding of equalizers and hitches and will clarify many problems which, on the surface, appear to be complicated and perplexing.

As the first general case, take the conditions which are represented in Fig. 1. The load moves in the direction a b and the prime-mover in the direction c d. The hitch is attached to the load at the point b and to the prime-mover at the point c, in such a manner that the drawbar takes the direction b c. The line a b is parallel to the line c d, both of which are parallel to the z-axis. Let the tension in the drawbar b c be represented by F, and designate the angles which this drawbar makes with the x- y- and z-axis respectively as α, β and γ. The force from the load acts upon the motor in the direction c b, and can be resolved as follows:

$$F_x = F \cos \alpha$$
$$F_y = F \cos \beta$$
$$F_z = F \cos \gamma$$

If a tractor is used force F_x will tend to pull the rear end of the prime-mover to the right and swing the front end to the left. Force F_y will produce a downward pull upon the tractor. The exact manner in which this affects the operation of the tractor will depend upon where the point of attachment c is placed with reference to the wheels. The force F_z is the effective force acting opposite to the direction of motion.

The effects produced upon the load are equal in magnitude and opposite in direction to those produced upon the prime-mover. F_z is the only force which is effective in the direction of motion and is therefore the only force which should be taken into consideration when computing the drawbar horsepower required to move the load. Suppose that this unit moves at the rate of n feet per minute, then

$$\text{Hp.} = \frac{F \cos \gamma . n}{33{,}000}$$

Very few hitches, however, are as simple as the general case just considered.

In general (eliminating a few patent hitches seldom used) tractor-plow hitches are of two classes, differing essentially in the range of adjustments permitted at the plow.

In Fig. 2 a hitch is represented which allows a very wide range of horizontal adjustment in addition to a vertical adjustment. The hitch illustrated in Fig. 3 has a very desirable vertical adjustment, but the range of the horizontal adjustment is more limited than in the case of the hitch illustrated in Fig. 2.

These hitches both contain the same fundamental elements—three bars making a rigid triangle with a single point of attachment for the clevis which makes the connection between the hitch and the tractor.

In order to illustrate the method of analyzing these hitches for the purpose of comparison a few typical cases will be considered.

Unfortunately, it is not known whether the forces which resist the motion of a plow can be resolved into a single force and a couple. In either case, however, it is evident that there must be some line in which the resultant of the forces which move the plow should act, in order to give a minimum draft and to produce conditions most favorable from the standpoint of operating the plow.

In this paper the resultant of the forces resisting the movement of the plow will be represented by a single force. Any error which may be involved in this assumption can easily be

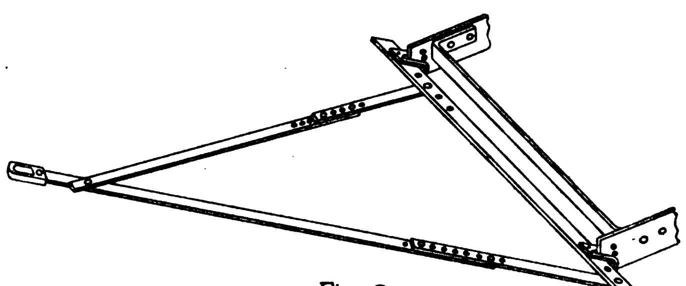

Fig 2

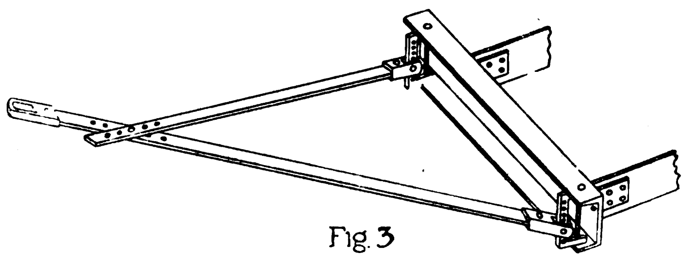

Fig 3

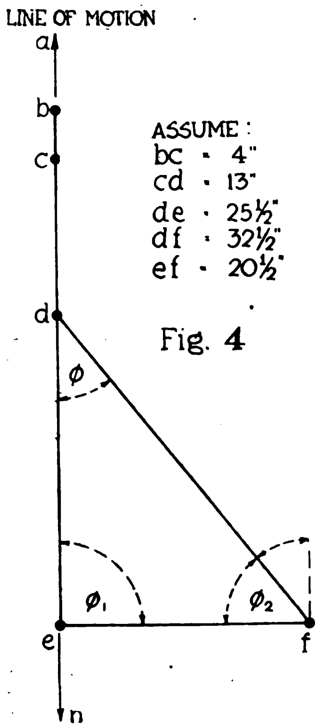

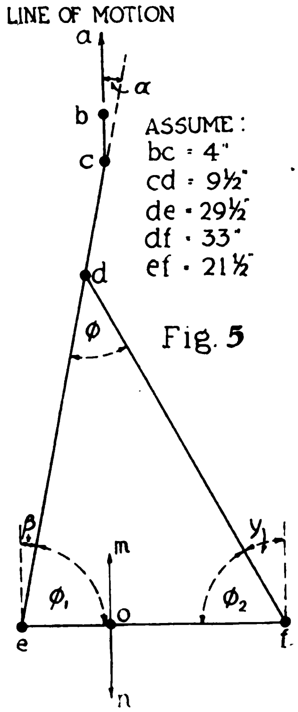

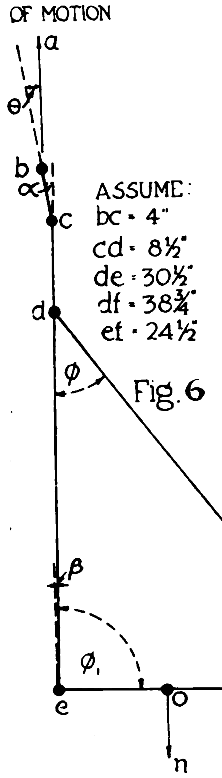

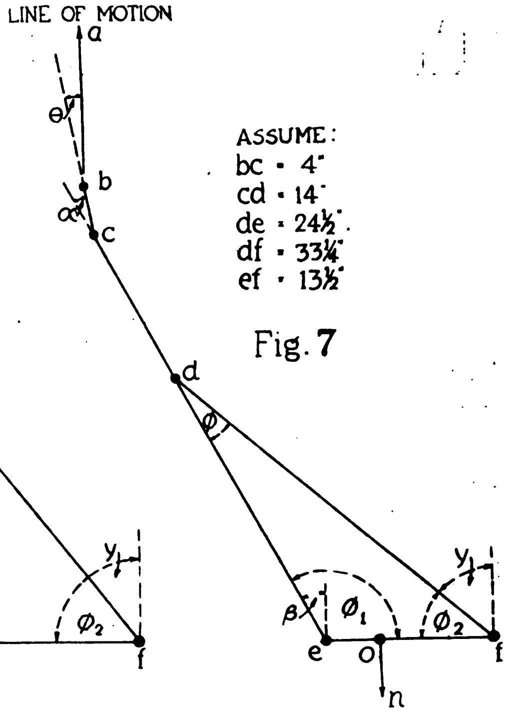

taken account of if later investigations prove it to be incorrect. Further, the effects of the vertical angle of hitch are omitted from the discussion.

In Fig. 4 the adjustments are such that the clevis, *c b*, connecting the hitch and tractor falls in the line of motion of the center of resistances of the plow, *e n*. In this case there is no side-draft on the plow. If the line of motion of the resultant of the forces tending to move the tractor falls in the line *e d* extended, there will be no side-draft on the tractor.

If, however, this resultant from the forces of the tractor does not fall in the line *b c* extended there will be a tendency to rotate the tractor equal to the moment of the couple produced. In the hitch the entire load is carried on the member *c e*. The member *d f* is neither in compression nor tension. It is useful on the turns or when the plow strikes an obstruction which tends to force it out of the line of motion.

In Fig. 5 the member *b c* is parallel to the line of motion, and falls in the same line *o n* as that produced by the motion of the center of resistances of the plow. In this case there is no side-draft on the plow. The only problem then is to analyze the strains produced in the members of the hitch. The method here presented is general and therefore will be given in detail.

Let the tension in the clevis *c b* be *F* pounds. The tension along *c e* is

$$F_3 = F \cos \alpha$$

Acting perpendicular to *c e* is a force.

$$F_4 = F \sin \alpha$$

This force F_4 acts upon *c d e* as lever and produces tension in *d f*, which will be designated as F_5. From the law of levers

$$F_4 \, (39) = F_5 \, (29.5) \sin \phi$$

$$F_5 = F_4 \frac{39}{29.5} \times \frac{1}{\sin \phi}$$

From this lever there will be a reaction at point *e* (F_6) Taking moments about *d*:

$$F_4 \, (9.5) = F_6 \, (29.5)$$

$$F_6 = F_4 \times \frac{9.5}{29.5}$$

F_6 can be resolved into two forces, F_7 acting perpendicular to the line of motion and F_8 acting parallel to the line of motion, but in the opposite direction

$$F_7 = F_6 \cos \beta$$
$$F_8 = F_6 \sin \beta$$

At point *e* F_5 can be resolved into two forces, F_9 which acts parallel to the direction of motion, and F_{10} which acts perpendicular to the line of motion.

Similarly at point *a* the force F_5 can be resolved into two forces, F_{11} and F_{12}, which are respectively parallel and perpendicular to the line of motion.

Then it follows that:

$$F_8 + F_9 + F_{11} = F_3$$
$$F_7 + F_{10} + F_{12} = 0$$

If the point of attaching the clevis to the hitch does not fall in the line of motion of the center of resistance of the plow then the conditions illustrated in Fig. 6 may arise when the hitch shown in Fig. 2 is used. Under these conditions the clevis *b c* will make an angle *α* with the line of motion.

Let the tension in the clevis be *F* pounds. At *B*, the point of attachment to the tractor, this force *F* can be resolved into two forces, viz., $F_1 = F \cos \alpha$ which opposes motion of the tractor and $F_2 = \sin \alpha$ which acts perpendicular to the line of motion and tends to rotate the tractor.

In cases of this kind the point of attaching the clevis to the tractor is usually to the right of the line of motion of resultant of the forces which move the tractor.

The moment produced by the force F_2 will act in the opposite direction to the couple tending to rotate the tractor. As a special case these two moments would balance each other. The stresses in the members of the hitch can be analyzed in the same manner as given above for the illustration in Fig. 5.

As the point *c* does not fall on line *n o* extended there will be side draft on the plow. The force F_1, acting at point *c* in the direction of motion, is opposed by an equal force applied at *o* acting in the direction *o n*, which is parallel to the line of motion.

The moment of this couple is F_1 multiplied by the perpendicular distance from the line *n o* to the point *c*, and it will tend to rotate the front end of the plow to the right. Opposed to the action of this couple is the moment of a force F_2 applied at *c* acting over a lever arm of unknown length. The increase in draft due to this hitch will be directly proportional to the difference between these two moments.

The conditions represented in Fig. 7 may occur when the hitch represented in Fig. 3 is used. In the ultimate analysis the tendency to produce side draft on the plow and tractor will be the same, but the stresses in the hitch have a very different distribution than in the hitch in Fig. 6.

Counteracting the Propaganda of the Irreconcilables

How Racial Conditions in Our Large Industrial Centers Have Accentuated the Problem—The Effect of an Inadequate Educational System

By Harry Tipper

THE strike which has occurred at the Willys-Overland Company in Toledo brings up again with particular force the division in the labor union ranks and the fight which exists between the labor unions and the radical elements who are taking advantage of the present situation to organize workers in a number of industries and to induce strikes on the basis of their more extravagant promises and more definite position. These radical movements are backed by the irreconcilables in the labor ranks who can see no good in the compromises which have marked the progress of the older and parent unions and who do not want to see any value in such compromises. These irreconcilables are committed to a policy of warfare with the object of direct control. Their position in respect of both the older and more stabilized unions and the manufacturer are sufficiently indicated by three paragraphs herewith taken from the printed propaganda of the Metal and Machinery Workers' Industrial Union, which is a branch of the I. W. W.

We have noted in these articles from time to time the tendency which exists within the ranks of the labor union for the radicals to gain control under various local conditions which favor that control because of the broad character of the promises and the plausible character of their propaganda.

The unions which are affiliated with the American Federation of Labor find themselves unable to meet or even countenance all the demands which come from dif-

THIS KIND OF PROPAGANDA MUST BE COUNTERACTED

"THE old craft unions can do nothing for us. In the first place, th are controlled by a gang of reactionary politicians whose main object is to hold on to their comfortable, well-paid positions and continue to deliver the workers to the employers like a herd of slaves. They invariably defeat any radical movement among the members. They are able to do this because the A. F. of L. unions are controlled by the officers, not by the members at large."

"WE must have one big union of the workers in each industry, and these unions must be bound together into one mighty organization, which shall reach out to our fellow workers in other countries and unite the workers of the world in one universal brotherhood, with one common aim, the abolition of the capitalist system and all its evils, low wages, long hours, unemployment, industrial slavery and commercial wars. While capitalism lasts, no worker's life is safe."

"FELLOW-WORKERS, the day of the inevitable industrial revolution is near. Signs of the approaching overturn are on every hand. No one can tell when the final break-up will come, but no one will deny that it is coming rapidly. We must not be caught unprepared. The workers must make ready to take over the industries, or our civilization will go down in ruin.

"One enemy, one union, must be our watchword."

□ □ □ □

AND THESE WILL COUNTERACT IT

AMERICANIZATION of the mixture of races which provides fertile ground for the promulgation of theories which can be so plausibly presented.

Education which will carry with it enlightenment on economic facts and will offset traditions arising from political backgrounds which facilitate the spreading of such propaganda by those who are familiar with the ideals, the racial instincts and the political history of these races.

Intelligent co-operation with the conservative body of workers who have no desire to see this sort of program succeed and with the more powerful members of the affiliated unions who are as little in sympathy with this program as are the manufacturers.

Time and patience expended by the manufacturer in understanding the worker's position, the worker's point of view and the things which he really desires.

ferent sections of the local bodies and from the different trades. The long experience which they have had in organization work, their continued contact with manufacturers in the settlement of disputes, their knowledge of the responsibility which attaches to the action of the unions have brought some measure of understanding in social obligations so that they are in comparison conservative in their attitude, and their constitutions do not contemplate much more than what they may consider a fair day's work for a fair day's pay. The consequence is that the leaders of these unions have been obliged to discountenance many of the demands of the radical elements in the local unions and in the national bodies. They have been obliged to urge conservatism in the actions of the unions and they have been obliged to recognize the social responsibility which goes with organization power.

These interests have failed to meet the desires and wishes of the radicals and they furnish the groundwork upon which the irreconcilable socialists in the ranks of labor have formulated their propaganda in favor of organizations like the Industrial Workers of the World and in favor of a regrouping of local unions for a larger and broader program of labor demand. The propaganda issued by these irreconcilables is very frank, may be termed brutally frank without overstating the case. It is directed equally against the American Federation affiliations and against the so-called capitalist. It is not only strong propaganda, but it is intelligently written in such a way as to inspire the greatest resentment, to magnify the irritation which may exist in the mind of the worker who is not satisfied with union action and to keep the industrial unrest constantly seething.

Radical Element Took Advantage of War Conditions

Attention is called to it at this time because the detailed reports of occurrences in many industrial cities would indicate that this propaganda is affecting a larger section of the working population than it did before the war and that the indefatigable workers who are behind it are taking advantage of the conditions which have existed during the war and during the armistice period, when the American Federation of Labor has frowned upon excessive demands and strikes, to push this propaganda to the uttermost. The importance of this problem is accentuated by the racial conditions in many of our large industrial centers where the mixture of races provides fertile ground for the promulgation of theories which can be so plausibly presented. Their fundamentally destructive character is not understood by the workman, who is allured by their promises and incited by their denunciations. The Americanization of these races has not yet progressed to the point where they are familiar with the ideals, the machinery and the inherent value of representative organizations. They know little or nothing about economic facts, their traditions arise out of political backgrounds which form excellent soil for such propaganda, and they are worked upon, in almost all cases, by members of their race who are thoroughly familiar with their ideals, their racial instincts and their political history.

The men who are committed to this sort of propaganda, who are committed to control industry and not merely to democratize it, who can see no value in industrial peace under present organizations or modifications of them, but who are engaged in keeping alive the unrest and stimulating it on the theory that warfare must inevitably lead to the control of industry by the workers, these men cannot be reached by any decent organization means. They will not countenance any orderly method of improvement and they are not concerned with organization developments looking to industrial peace and the preservation of the best elements of the present system, which has lasted a good many years and which has so much of important value. Wherever the local unions or the local workers get into the hands of these irreconcilables and are induced by them to organize for the purpose of their deliberately excessive demands, there is no hope of arriving at a solution until the power of the organizers over the local body of workers is broken. No attempts at adjustment will stave off the trouble where this occurs, and strikes and probable trouble in connection with the strikes must be expected.

Counteracting the Irreconcilables

The conservative body of workers who have no desire to see this sort of program succeed and the more powerful members of the affiliated unions who are as little in sympathy with this program as are the manufacturers, are of importance in combating this propaganda, and careful, co-operative and educational methods will aid very greatly in stabilizing the situation. The large body of the workers who are temporarily misled by the specific promises of such agitators and who are allured by their indefinite pictures of the future, can be reached by the manufacturer if time and patience is expended in understanding the workers' position, the workers' point of view and the things which he really desires.

At no time in the history of developments in the United States has the old Scotch business philosopher's statement been of such importance as it is to-day. The statement that it was vitally necessary for the executive to understand those who were under him while there was no corresponding probability of the converse. It is this necessity in the labor situation which demands a degree of patient consideration and a degree of faithful promotion, by the manufacturer, of all plans prepared for the improvement of the worker's condition and and a constant education of all supervisors, so that a confidence may be established which will itself be the most effective means of combating the minority propaganda with its persistent attempts to maintain the industrial unrest.

The other day a manufacturer made the statement that the workers' demands were unreasonable, that they did not seem to appreciate the fact that if their demands were acceded to the business could not continue, and they did not seem to understand or care about the fundamental economic facts. There is no doubt that in a good many of the local strikes which have occurred in the last few months the demands of the local bodies of labor have been excessive and the statements of the leaders of many of these bodies have borne a remarkable resemblance to the propaganda of the I. W. W. and similar irreconcilable radical bodies.

The Influence of Inadequate Education

An examination of the educational work which is done in the schools, a little understanding of the atmosphere by which these men are surrounded, a careful study of the reading which forms a large part of their means of acquiring information indicate that it would be very remarkable if they showed any understanding of the fact that their demands are excessive or any appreciation of the economic fundamentals.

In the public education in the various states of the Union and in the high school education, very little attention has been paid to the proper teaching of the reasons for industrial organization. As it is, in very few cases have manufacturers concerned themselves with the character of the education or the surroundings of their workers, and even where educational processes have been

The Webb Law in Operation

Two Views of the Act Permitting Combinations for Export Trade—The Legal and the Business Viewpoints—How Combinations May Be Affected

By Allen Sinsheimer

AS a result of study by legal and business authorities, two distinct views of the Webb-Pomerene law, authorizing combinations of American manufacturers for export trade, have been developed.

One conception foresees legal pitfalls for all combines organized under its authority and predicts that business will find itself mired in a quicksand of trouble, with consequent penalties. This is the view of the lawyers, who naturally note chiefly the legal disasters that may arise from the phraseology.

The other view is optimistic. It foresees the Government co-operating, for the first time, with business, rather than acting the part of the overseeing policeman. This view prophesies that through the Webb law business may promptly develop export trade and compete equally with foreign manufacturers. It pronounces the bill to be the most important step taken to advance and maintain American foreign trade. This is the view of business men who have studied the act and some few lawyers whose perspectives reach beyond the merely legal aspect.

Both views were discussed at the recent Foreign Trade Convention at Chicago, where all the manufacturers present voiced a unanimous approval of the act. More than eighty combines have already been organized, it was stated, and are functioning without difficulty.

As it stands, the Webb-Pomerene act authorizes American manufacturers to organize combinations to engage in foreign business which will not be called illegal under the Sherman act.

The pitfalls pointed out by various lawyers are found in Section 2, which is to the effect that any combination organized under the Webb law will be found guilty of illegal practices if it restrains trade in the United States or restrains the export trade of a domestic competitor or artificially or intentionally increases or decreases the prices of its commodities sold either in foreign or domestic markets.

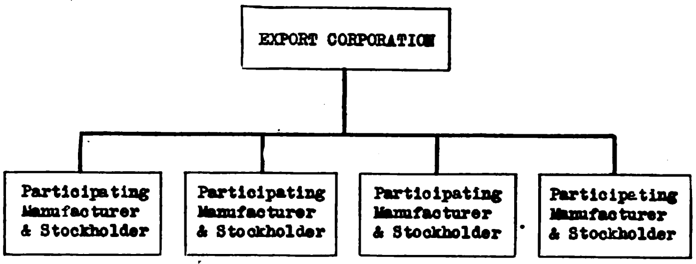
Three Questions Which the Lawyers Ask

Under these legal limitations lawyers find three questions arising:

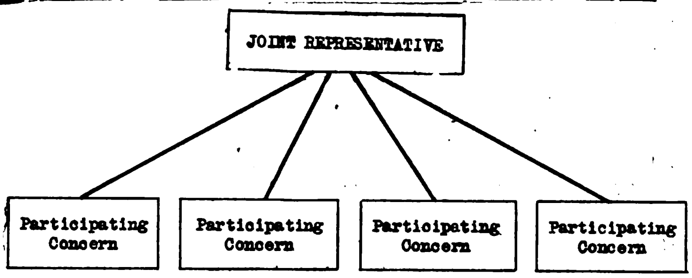
1. If a combination of American manufacturers exports such quantities of merchandise as to diminish the domestic supply and thus force an increase of domestic prices, will it be enhancing prices in the United States in conflict with the provisions of Section 2?

2. If a combination of American manufacturers undersells another combination of American exporters abroad to the extent that the competitor's business is ruined both abroad and at home, will it be acting in restraint of trade?

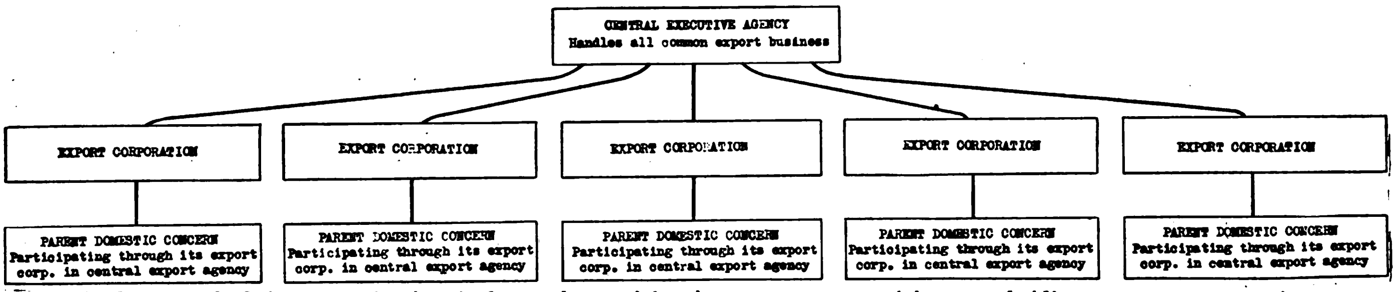
Three Methods of Organizing Export Combinations Under the Webb Law



The most commonly used method is the organization of a corporation by a group of manufacturers with the participating concerns as stockholders. The export corporation operates as an independent concern



Another, and very simple, form of organization is that where the participating concerns form an association by joint agreement through a joint representative who assumes charge of the foreign business



A third method for organization is by each participating concern organizing a subsidiary export corporation with each of these entering into an agreement for handling all export business through a central agency

Practically all of the manufacturers and some of the legal advisers, including John Walsh, former chief counsel of the Federal Trade Commission, were inclined to regard these questions as being more or less superficial. They believe that the act, which in itself for the first time in legislative history does not provide a penalty for the first violation, but merely a recommendation by the Federal Trade Commission to violators, was intended by Congress to be purely an aid to American business and not an obstacle. The possible pitfalls caused by the legal limitations will be accepted, it is thought, by the Federal Trade Commission in a broad light, and no attempt will be made to prosecute concerns unless they practice dishonest or positively unfair methods. In other words, it will be the policy of the Government, according to the manufacturers' viewpoint, to co-operate with American business throughout, and manufacturers may combine under the provisions of the act and plan to engage in foreign business without fear of any Government interference, provided they engage in honest business.

May Undersell Competitors

Question No. 1 was disposed of by the general acceptance of the belief that manufacturers who would meet and pledge certain quantities of their supplies for export once each year prior to the beginning of the year's campaign could in this way display their honest intentions and be able to overcome any legal questions that might arise even if the domestic supply were thus diminished and domestic prices increased as a result.

American combinations organized under the act may undersell their American competitors abroad regardless of the provisions of Section 2 if they can prove that their methods of production and operation of business warrant their sales at lesser prices. In other words, in answer to Question No. 2, they may undersell if they do it by fair and honest methods.

Question No. 3 was answered by statements that American manufacturers might sell a commodity abroad for less than the domestic prices without enhancing domestic prices if the foreign prices were reduced to meet foreign competition. If, however, prices are reduced only in certain localities abroad merely to meet American competition or without justification, this, it was thought, would be regarded as an enhancement of domestic prices.

It is unfortunate that the provision in Section 2 was drawn in its present manner, for it creates a situation whereby the Sherman law is suspended in behalf of American exporters yet at the same time is held over the exporter as a club in the event of violation. It can be assumed, however, that the Government will not undertake to penalize an export association for openly practising methods it regards as proper under the law, but it will probably be well for the protection of associations to constantly keep the Commission informed of the practices planned and engaged in.

Act to Be Broadly Interpreted

That a broad view of the act may be expected of the Commission is displayed in its statement that: "It is not reasonable to suppose that Congress meant to obstruct the development of foreign commerce by forbidding the use in export trade of methods of organization which do not operate to the prejudice of the American public, are lawful in the countries where the trade is to be carried on and are necessary if Americans are to meet competitors there on more nearly equal terms."

That the act will allow combinations to engage in many practices not directly export trade but indirectly connected with it was the opinion of Mr. Walsh, who stated: "Although the act strictly defines 'export trade' and exempts from the penalties and restrictions of the Sherman act only 'an association entered into for the sole purpose of engaging in export trade and actually engaged solely in such export trade,' still it must be assumed that the Congress had in mind the fact that under the corporation statutes of the various states and the District of Columbia every corporation is vested automatically with certain incidental powers and that it would be a practical impossibility to form a corporation with no powers other than that of being engaged solely in export trade.

"It is a general rule of law that a corporation possesses not only the powers specifically conferred upon it by its charter but also such as may be fairly implied from those powers, including all that are essential to the declared object of its existence. Therefore, it may be fairly assumed that an export association may among other things establish and maintain agencies and act as agent in foreign trade, acquire, equip and operate wharves, warehouses, elevators, ships, and acquire, dispose of, pledge, mortgage or lease property, real or personal, subject to legal restrictions, and to do many other acts incidental to the business of export trade."

Phraseology of Doubtful Meaning

Other sections of the act also include phraseology and provisions that should have the attention of exporters. Section 1 indicates, for example, by the words "exported from the United States to any foreign nation" that export products must actually be sent to a foreign nation. Again, by the use of the phrase "or selling for consumption or for resale" within the United States, Congress has left opportunity for misunderstanding. It is clear that an export association must not sell for domestic consumption, but it is not clear whether such an association may manufacture for consumption or resale in the United States.

Section 3 allows a corporation to hold or acquire or own any part of the stock of an export corporation which is organized actually to engage in export trade unless the holding or owning of such stock will restrain trade or lessen competition within the United States. This will allow associations to take over the export department of some established manufacturer if they so desire.

Section 4 provides that any exporters who are engaged in unfair practices which interfere with or obstruct free competition, such for example as selling below cost, will be found guilty of illegal methods. This section is a powerful one and can be used to prevent all trickery and fraud.

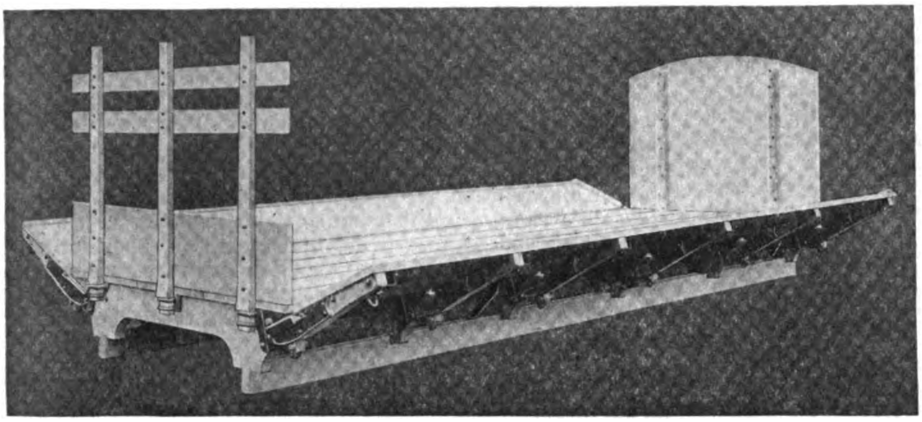
Export Associations Must File Statement of Ownership

Section 5 provides that every association formed to engage solely in export trade must file a statement with the Federal Trade Commission within thirty days after its creation, giving the names of its officers and stockholders, its by-laws, if any, and make like statements each year. The second paragraph of Section 5, which provides that the Federal Trade Commission when it discovers any violations of the act may summon the officers of an association and make recommendations for readjustments, is designed to enable the Government to guide export associations definitely and to avoid the confusion which has resulted in business circles since the passage of the Sherman law.

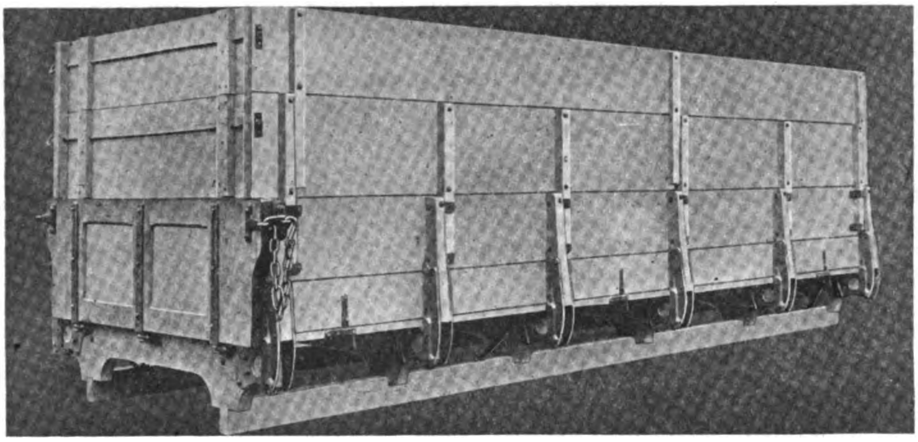
The use of the term "foreign nations" is taken to mean any land except the Hawaiian Islands, Porto Rico, Alaska and the United States proper. The term "commerce" is taken to imply navigation, and consequently grants permission to operate ships for both export and import.

Republic All-Purpose Farm Truck Body

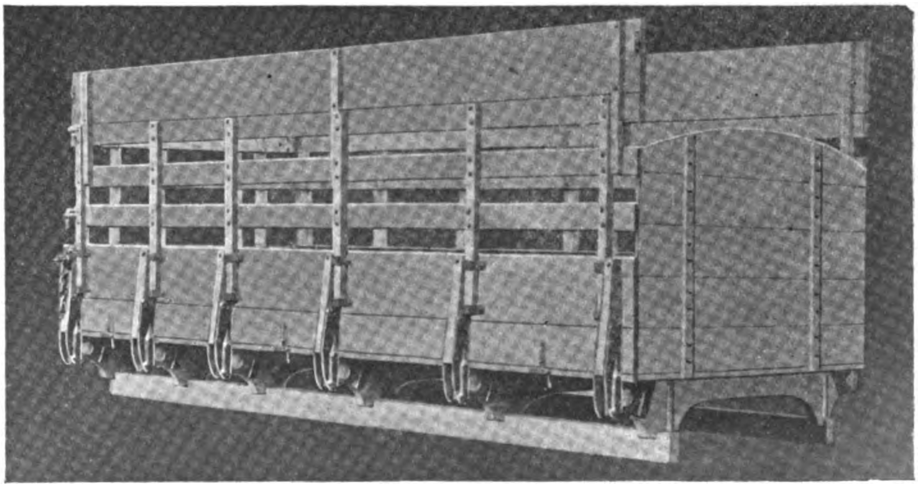
Can Be Quickly Converted for Different Uses Covering the Whole Range of Farm Haulage



Platform hayrack useful in hauling hay, wheat, oats, cornstalks, etc. By using a different set of supporting stakes we obtain a platform with level extension side boards, head board and end gate, suitable for hay, grain in bags, cement in bags, fertilizer in bags, fruit produce in crates, poultry in crates, farm machinery, dressed meats, fence posts, etc. Entirely removing the extension boards makes a platform type truck with head board and end gate adapted to stone hauling and other heavy duties



Three-section tight removable side box for barnyard fertilizer, cabbage and bulky produce. Removing top side boards makes a combination grain, apple and potato box with two-section tight removable sides. Removing the remaining side boards gives a regulation wagon box with removable sides and end gate arranged for hauling loose materials such as coal, dirt, gravel, grain, etc.



Cattle rack type adapted for hauling cattle and also transporting cotton and similar materials requiring a rack enclosed body. Removing the side boards converts this into a combination stock and basket rack box suitable for hauling hogs and sheep and crated goods

AN all-purpose farm body has been brought out by the Republic Motor Truck Co., Inc., of Alma, Mich., for use with Republic trucks. The body is designed to give the farmer a wider range of use for his truck. Eight types of bodies are combined in one, and so designed that one man can adjust it to any desired type in a few seconds.

The body is made of kiln-dried hardwood lumber and well ironed so as to prevent rattles. It is made in two sizes, known as Nos. 1 and 2. The No. 1 body is 9½ ft. long and is a combination platform and wagon box, as illustrated. The bare body sells for $115.

No. 2 body is 11½ ft. long and is a combination platform and wagon box, as illustrated, selling for $135.

The extra side racks to convert the body into grain, fruit and cattle type are $33 on the No. 1 size and $36 on No. 2. The weight of the No. 1 body, combination platform and wagon box only is 500 lb., and of No. 2 600 lb. All the paint work on these jobs is standard green with light green stripes.

Some of the different types of bodies are illustrated and the purposes for which they are intended are outlined.

This is apparently one of the first attempts to solve the truck-body problem from the standpoint of the use of motor trucks on the farm. Loads of such wide variety have to be transported in this service that convertible bodies are really essential.

The FORVM

Liquid Fuel Injector

By Henry B. Higgins, Jr.

THE primary object of the device shown in the drawings is to simplify the "direct-injection" type of oil engine so that its use becomes practicable in the relatively small, high-speed units employed in trucks, tractors and similar service where operating conditions are often severe and good care is seldom available.

The most efficient means yet devised to insure the perfect combustion of fuel oils consists in spraying them direct into the combustion chamber by means of a jet of compressed air as the piston begins its working stroke. This charge may be ignited as it enters the chamber by means of an electric spark, hot surface, or the heat of the suddenly compressed injection air, or by the Diesel method.

The advantages of this type of engine over those operating on the Otto cycle, employing atmospheric carbureters, mixers, etc., together with various heating arrangements, are well recognized. Following are some of them:

They start readily on their regular fuel without priming, preheating or other preliminaries (except where hot surface ignition is used).

They are flexible in operation and not particularly sensitive to atmospheric variations.

Thorough combustion of the fuel is secured, practically eliminating smoky exhaust, fouled cylinders and valves, and the serious troubles incident to dilution of the lubricant by unburned fuel.

As no fuel is present in the working cylinders until used, preignition is impossible, eliminating the need of water injection.

Combustion is not explosive; hence high compression may be used without excessive pressures ensuing, making for good fuel economy without excessively heavy construction.

It follows that they are longer lived and more economical, both of fuel and lubricating oil, generally using from 0.4 to 0.7 lb. of fuel per brake-horsepower hour.

In addition to economical operation, higher volumetric efficiency is possible, due to the induction of cold air and the absence of throttling or wire-drawing action of the atmospheric carbureter (necessary to provide sufficient air velocity to break up the fuel) upon the incoming air.

The principal factor which has confined these advantages to comparatively large engines has been the expensive, complex and rather bulky apparatus necessary for the supply of injection air. This usually consists of a two- or three-stage compressor, air cooler, receiver and high-pressure piping and connections, besides the admission valve to the atomizer.

Attempts have been made to avoid these by the use of the "solid-injection" system, wherein no air is used, fuel being sprayed into the cylinder by a high-pressure pump and atomizer under a pressure of 2500-3000 lb. per square inch; but so far they have not been entirely successful, partly owing to troubles with the high pressure fuel pump and connections and partly to the inferior quality of the spray entailing higher fuel consumption and dirty operation.

The device shown avoids the complications of the usual compressed-air system, while retaining its desirable features, to which it adds another—that regardless of whether the engine is being cranked over or running at full speed the quantity and pressure of the injection blast are absolutely uniform and a good spray can be depended upon, without undue wastage of high-pressure air, under all conditions.

It is applicable to either two- or four-cycle engines, and overcomes the usual objections to the two-cycle—backfiring in the base and loss of fuel through the exhaust ports while charging, thus increasing the usefulness of this simple and durable engine.

In effect, the system under discussion is a two-stage compressor, the compression in the working cylinder not only supplanting the first stage but also acting upon a small differential piston to further compress a small portion of itself for fuel injection. Except for a cam and rocker arm, or their equivalent, to time this operation by giving the small piston a slight initial lift off its seat, a check valve and the piston itself, which is practically frictionless except for the packing rings requiring little or no lubrication or attention, the device has no moving parts, and this slight added complication is more than offset by the elimination of the troublesome carbureter and ignition system.

While a small plunger pump for each cylinder is the most reliable method of measuring and supplying fuel for each atomizer, some form of gravity or low-pressure feed may be utilized, as it does not have to encounter any pressure. Any form of "open-type" atomizer may be used, those shown being among the simplest.

Figs. 1 and 2 show the injector applied to a two-cycle engine igniting by high compression and will serve to illustrate its operation.

In Fig. 1 it is ready to operate. Working piston *A* is nearing the top of its stroke and cam *K* is on the point of depressing the end of rocker arm *J*. The space above compressor piston *C* is filling with air at cylinder pressure, through valve *N*.

It should here be noted that the bottom face of compressor piston *C* is divided into two parts by the seat *D*. One portion, *E*, communicates with atmosphere through vent *H*. The other, *F*, is open to cylinder pressure. However, the area of the top face, *G*, of piston *C* is a little greater than that of *F*, therefore piston *C* is held tighter upon its seat as the pressure increases.

In Fig. 2 working piston *A* reached its firing point and cam *K* slightly lifted compressor piston *C*. The instant that this took place, vent *H* was cut off and the entire bottom face of piston *C* exposed to cylinder pressure, which caused this piston to move rapidly up and forcibly eject the air above it through atomizer *M*, spraying the oil contained therein into working cylinder *B*. A small space is left between passage *L* and the end of compressor cylinder *I*, in order to provide an air cushion for piston *C*.

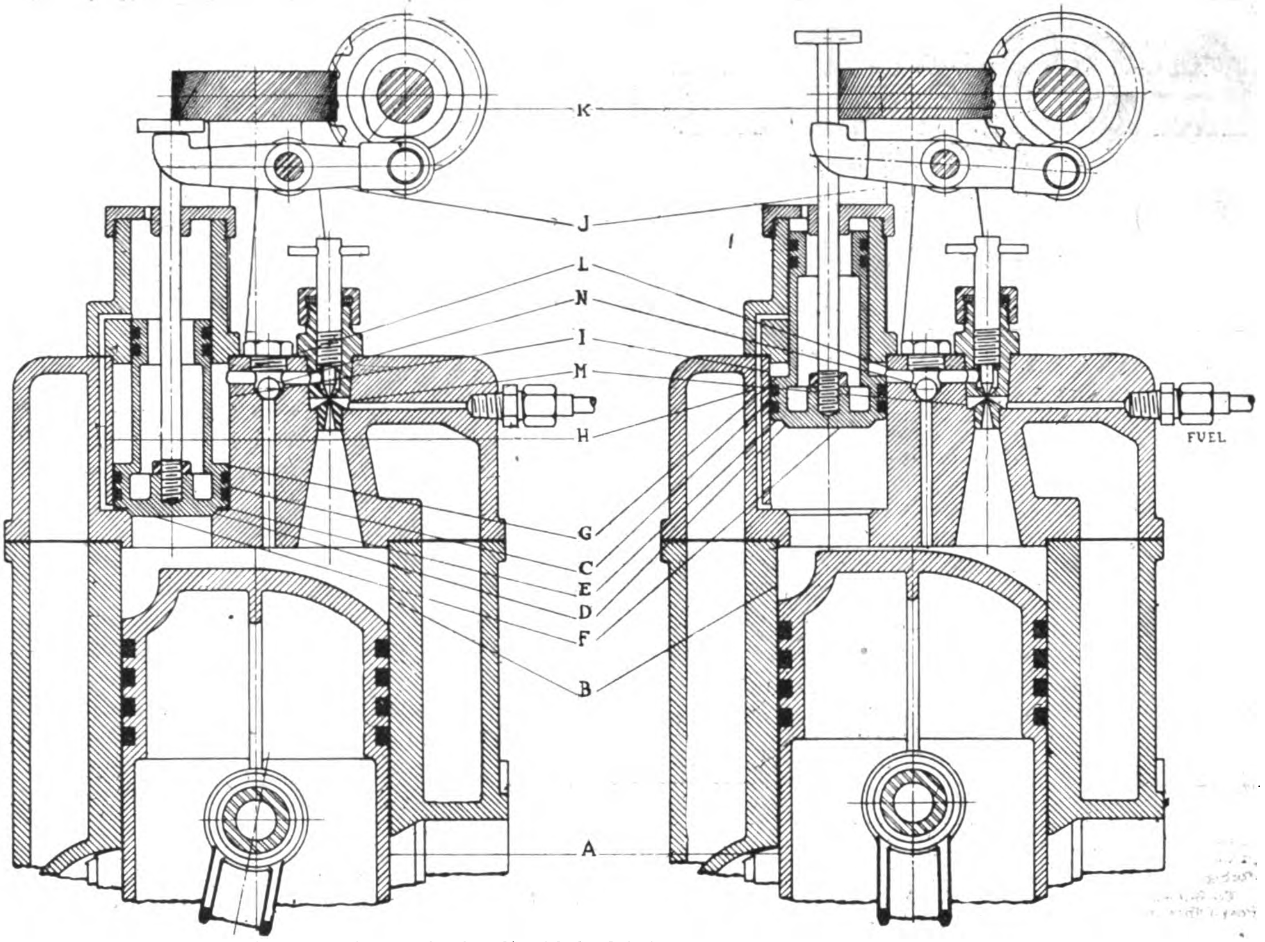
If the device is designed to compress to 350 lb. per square inch or more, the heat of the suddenly compressed air will be sufficient to ignite ordinary fuel oil before it leaves the atomizer, blowing it into the combustion chamber in the form of a flame. If it is desired to use lower compression, ignition may be effected by a spark plug or hot surface placed in its path.

The slight partial vacuum in the working cylinder during the charging period of the cycle (either two- or four-stroke) should be sufficient to return compressor piston 3 to its seat, or a light spring may be used if faster action is desired.

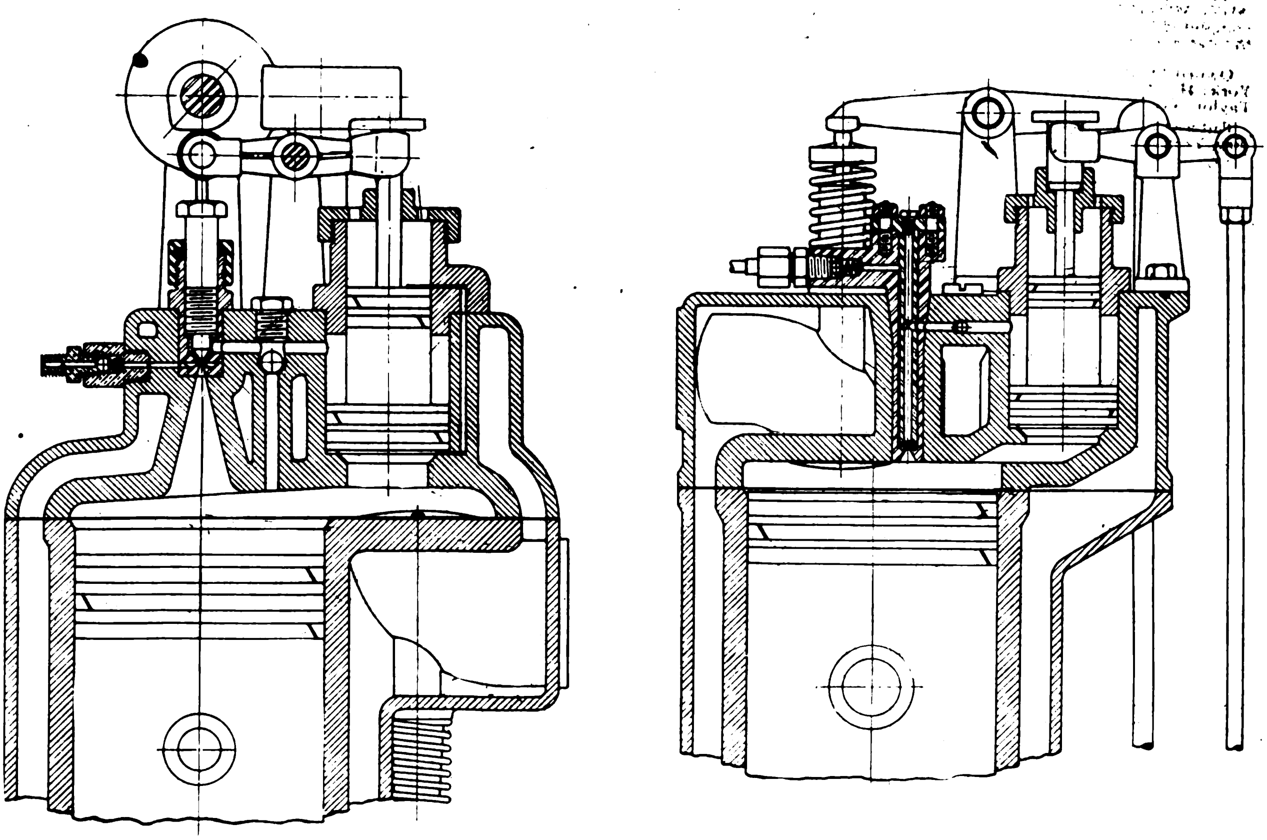
Fig. 3 shows a possible application of the injector to a four-cycle L-head motor, and Fig. 4 shows it in connection with a valve-in-head type.

A minor improvement is also shown in Fig. 4. A portion of the lift rod for compressor piston *C*, just below its head, is enlarged, this enlarged portion fitting into a counterbore in the upper head of compressor cylinder *H*, as the piston nears the bottom of its return stroke. The compression of air in the pocket thus formed serves to cushion the piston and prevent its unduly pounding upon seat *D*.

In conclusion, the drawings only show the principle of the device. Its various details may be arranged to conform to almost any type or size of engine. It is cheap to manufacture, and for most engines would involve no great changes in design. It involves no new and untried theories, but is merely an adaptation of the already successful large stationary and marine oil engines to the smaller units of the automotive field.



Figs. 1 *and* 2—*Higgins liquid fuel injector applied to two-stroke engine*



Figs. 3 *and* 4—*Application of Higgins liquid fuel injector to four-stroke L-head and valve-in-head engines*

Webb Act Will Aid Export Business

LESS legal advice and more sound business judgment should be the guide to exporters who consider forming combinations under the Webb Act.

The engineer believes that all the success of the automobile business lies in design. The production manager thinks it is all in manufacture. The sales manager will tell you it is entirely a matter of sales policy. And similarly the lawyer sees only the legal technicalities in the Webb Act.

He notes only how you may entangle yourself with the law and not how the law may help you to untangle export trade. He finds only the pitfalls in which combines may be caught and overlooks the sound government support by which industry can escape the pitfalls in foreign business.

The Webb Act is stated in its title to be specifically an act for the promotion of foreign trade. It was definitely intended as such by Congress and any attempt to use it for the entanglement of business would be a perversion.

That the legal authorities are wrong seems evident in the verdict of the Federal Trade Commission, which also finds it a law for the benefit of industry and not intended as a club over it.

It is a safe and sound opinion that American manufacturers may combine under the authority of the Act and develop a vast export trade regardless of the legal possibilities of the law so long as they conduct a fair and honest business.

The Aerial Convention

IT is obvious that the aircraft industry needs effective propaganda at the present time. Under Government nursing it has grown to large size in a few years, and now that Government support has been practically withdrawn, the industry has to stand on its own legs, as it were, which will be a difficult experiment at first.

All other branches of the automotive industry were successfully promoted by competitions and exhibitions in their earlier years, and there is no reason to doubt that the same method should be successful when applied to the airplane industry. The aircraft convention, exposition and contest being held this month at Atlantic City is a parallel to the "Nice weeks" of former years. Nice occupies much the same position as a shore resort in Europe that Atlantic City does in America. At Nice the automobile, the motor boat and the airplane have successively had their innings, and efforts were made there specially to promote the sale of the more expensive and luxurious cars, boats, etc.

Atlantic City has not figured very prominently in motor sports so far. There can be no question, however, that it is a suitable place for spreading the gospel of aerial transport. During the month there will probably be several hundred thousand visitors at the resort from all parts of the country, as well as some from foreign countries. These will largely represent the wealth and the business interests of the country, and if a favorable impression can be made with these classes, a very good beginning will have been made toward popularizing the airplane.

The program which is being carried through consists mainly of illustrated talks on different phases of aircraft work. Among the possible applications of aircraft covered in these talks are forest patrol, police service, mail service, overland and overseas transport and exploration. There will be talks on the medical, legal and insurance phases of aerial travel. Numerous are the contests for which prizes are offered, and with the exception of the prize for the transatlantic flight from Atlantic City, all are likely to be won during the month, as the conditions attached to them do not appear at all difficult in view of the progress made in airplane construction.

There is also scheduled for the end of the convention a series of engineering sessions. It is very likely, however, that the lectures and discussions (if any) will be of a popular character, though dealing with the engineering phases of the airplane.

Legislative Meddling with the Fuel Problem

CALIFORNIA legislators recently took it upon themselves to solve the motor fuel problem by law and in about a week's time introduced no less than three bills embodying proposed standard specifications for gasoline, in the State Legislature. Happily this legislation was smothered, but inasmuch as it is very likely that other states will venture similar legislative action in the future, it may not be amiss to show the futility of the thing.

It is true enough that purchasers of motor fuel are experiencing certain difficulties with the product sold them. Gasoline is not what it was ten or fifteen years back. But we have long become reconciled to the changing quality of gasoline and have endeavored to adapt our engines to it. It is not a matter of human perversity but of immutable natural laws. The amount of petroleum which can be pumped from the earth is limited; in fact, according to figures given out by representatives of the Fuel Administration, the whole unmined supply will last only for about a score of years. The demand for gasoline is increasing faster than that for any other petroleum products, and to meet it the oil companies have found it necessary to increase this supply by every known means, such as including heavier fractions and rendering the fuel usable in engines by blending with casing-head gasoline, converting kerosene or gas oil into gasoline by the cracking process, etc.

The Law of Supply and Demand

How the law of supply and demand is asserting itself in this connection was well brought out in a recent lecture by a representative of the Bureau of Mines, who said that the cost of processing was substantially the same for kerosene and gasoline; that the only reason gasoline sold at about twice the price of kerosene was that the demand for gasoline was relatively much stronger.

This inexorable law of supply and demand will continue to assert itself, and if we wish to have all the fuel we will need for the rapidly growing number of gasoline engines we will be obliged to use heavier and heavier fuels in spite of whatever legislation we may pass. If we stipulate that gasoline must not show lower than 60 deg. Baumé at 60 deg. Fahr., then most of us will soon have to burn something called by a different name—and the change in name will not help us in our carburetion difficulties.

The problem of standard specifications was taken up some years ago and we thought that the subject had been definitely laid aside, the conclusion having been reached that such a standard would have to be continually modified and therefore would be of no practical value. If a specification should be adopted that called for a really high-grade gasoline the result would be that, owing to scarcity of the available supply, the price of such a fuel would soon rise beyond all reason, and every garage would be compelled to sell another grade of fuel, at a price within the reach of the average consumer. It is self-evident that, with the more volatile fractions removed, this motor fuel would be less volatile and less burnable than what we now burn as gasoline. If we have understood the Bureau of Mines correctly, it has maintained the standpoint that the solution of the fuel problem lies in using straight-run fuel; that is, a blend of all the fractions of crude petroleum which can be successfuly burned in modern engines. If legislation like that proposed in California should be adopted widely throughout the country the effect would be just the opposite. The class of automobile owners to whom money is no object, who as a rule own the latest models that are best adapted to burn the heavier or poorer grades of fuel, would buy the high-grade fluid, and leave the man in moderate circumstances, with his superannuated machine with weak fuel-digestive organs, to get along as best he may with the poor stuff. Instead of remedying that fuel situation such legislation would really aggravate it.

Another reason why legislation of the character referred to is objectionable is that when it is taken up by different states and handled in different ways it will lead to confusion. What a burden it would be to the petroleum refiners if they had to produce and store gasoline of different grade for each State! Also, the engine manufacturer could hardly be expected to turn out different classes of engines to suit the "legal fuels" in different states. The lot of the engine manufacturer and the engine user would certainly be the easiest if one uniform grade of fuel were sold throughout the country—the best that the proportion of demand to supply would allow. And sectional legislation of the character proposed in California, instead of furthering this end, would defeat it.

America's Lead in the Motor Industry

EUROPEAN automobile manufacturers are not unmindful of the fact that from the beginning of the war, when all passenger car manufacture for private account stopped with them, for a period of four years the American industry continued to improve its designs, and as a result has achieved a substantial lead in motor car construction. Some have sent representatives to this country to study our latest practice, while in one or two instances American designing talent has been engaged abroad to introduce our methods.

Previous to the war European and especially Continental manufacturers looked upon the American chassis with scorn. It was said, for instance, that it would never satisfy the artistic taste of the French purchaser. Possibly at the present time in France the exigencies of commercial life are a stronger factor than the artistic instinct. At any rate, American achievement in the automobile line is no longer deprecated and literature on our methods of design and production is in demand abroad.

Saxon Reorganization Plan for Formation of New Company Perfected

New Corporation Will Be Financed by New York and Chicago Bankers —Digest of Plan—Creditors to Receive Stock for Value of Claims Against Present Company

DETROIT, May 13—The Saxon Motor Car Corp. refinancing plan continues to make steady progress. Matters directly connected with the securing of additional capital necessary to put the company on its feet have not been completed by the creditors' advisory committee as yet, but will follow when all details connected with the proposed reorganization are effected. All of the bankers and the majority of the merchandising creditors have approved of the plan which calls for the formation of a new company to be capitalized for $6,450,000, the liquidation of all present stock, and the assuming of all liabilities by the new organization. The creditors are to receive stock for the value of their claims against the present company. The present stockholders are to be given stock in the new company according to the present plan.

Since June, 1917, the affairs of the Saxon corporation have been conducted by an advisory committee of creditors, consisting of: Chairman, William J. Gray, vice-president of the First & Old Detroit National Bank, Detroit; Ralph Van Vechten, vice-president, Continental & Commercial National Bank, Chicago; C. R. Talbot, vice-president, National Bank of Commerce, Detroit; C. W. Dickerson, treasurer, Timken-Detroit Axle Co., Detroit; W. R. Angell, secretary, Continental Motors Corp., Detroit; W. S. Thomas, vice-president and treasurer, Wagner Electric Co., St. Louis.

Has Paid Off 30 Per Cent

This committee has kept the company solvent through the application of a general liquidation policy and the extension of outstanding notes. Every 6 months the books are balanced, 10 per cent payment on obligations made, and the paper renewed. The company is now on its fourth 6-month period and has paid off 30 per cent of the original indebtedness with 6 per cent interest. The company's standing indebtedness to date is now approximately $2,450,000.

The new company is to be refinanced by New York and Chicago brokers, who have tentatively agreed to underwrite the stock. This matter, however, has not been formally settled inasmuch as the committee in control has had its hands full since the first of the year in, first, obtaining a 6-months time extension on outstanding obligations, and, second, in securing the consent of each individual creditor to the proposed reorganization plan. With the exception of a few minor creditors the indorsement of all has been approved, and the next step will be the taking up of the financing project with the brokerage firms.

A digest of the reorganization plan of the Saxon Motor Car Corp. is as follows:

The advisory committee of creditors who have been in charge of Saxon Motor Car Corp. affairs since June, 1917, will cause a new company to be organized to be called The Saxon Corp., and to acquire the title to the assets of the present company through application of claims of the depositing creditors. It is contemplated to organize with the following capitalization:

$2,000,000 in principal amount, 6 per cent gold bonds;

$1,250,000 issue of 8 per cent cumulative preferred stock;

$3,200,000 common stock, $100 par value, each.

War Conditions Affected Reorganization

The committee states that under war conditions previously existing it was impossible to interest capital in the enterprise, and that it is now apparent that a complete reorganization must take place. Efforts to induce the stockholders to work out some plan of reorganizing have failed. The enforced policy of gradual liquidation has reached its limit, and unless new capital is immediately secured to carry on the business, manufacturing activities must cease.

The present indebtedness of the corporation is approximately $2,400,000. The assets at book value exceed this indebtedness by $250,000, but in event of enforced liquidation the assets would bring but a fraction of the book value.

Creditors Will Take Stock

Under the plan, the present creditors will take stock equivalent to the value of their claim. Responsible bankers are ready to furnish capital by the purchase of bonds and preferred stock if the creditors take stock in payment of claims. The underwriters propose to manage the reorganized company for a period of from 3 to 5 years. If it is found impossible to transfer the assets of the present company to a new corporation, then the advisory committee, in the opinion of the creditors, should take steps to sell the assets of the company.

Common stock in the reorganized company will be deposited with trustees for a period of 3 years. This stock will be evidenced by the trust certificates, to be issued by the trustees, to be delivered to creditors as stockholders in the new company, but a continuing option will be given the banker to purchase within 3 years shares of the par value figures of $2,400,000, plus annual interest at 6 per cent.

Willys-Overland Strike Now a Matter of Principle

TOLEDO, May 14 (*Special Telegram*) —Watchful waiting is the policy adopted by both Willys-Overland Co. and their idle employees. The situation remains unchanged. Both sides refuse to give in an inch, but nevertheless an air of expectancy prevails. Toledo is full of rumors that an agreement is near. Since Saturday morning daily conferences between the workers and the company have been held, but an agreement seems far away.

Though the strike was called as a result of a controversy over hours, it has gradually taken the aspect as to whether or not Toledo will remain an open or closed shop town. The Merchants and Manufacturers Association has indorsed the Willys-Overland stand and brought down upon its head the wrath of unionized labor. The whole affair has developed into a matter of principle, not of hours, and the radical element predicts a general walk-out unless the cause of the strikers is victorious.

On the other hand, it is said the manufacturers are prepared to suspend all operations if serious difficulties develop. Both sides are leaving no stones unturned in their efforts to prolong the struggle.

Willys-Overland stockholders held their annual meeting Tuesday, and endorsed the stand of the company in handling the strike. A general assessment of 50 cents a day has been levied on all union men in Toledo. The boilermakers and iron shipbuilders have voted to stand by the Willys-Overland strikers, and other unions will take the same action, it is said.

In a statement to-day the Electric Auto Light Co. says it is prepared to operate its plant 48 hours a week if the majority of the workers approve such a schedule. This company is a subsidiary company of the Willys-Overland.

Automotive Industries

At the annual stockholders' meeting the Willys-Overland Co. elected the following directors: John N. Willys, C. A. Earl, James E. Kepperly, Edwin B. Jackson, C. O. Miniger, Royal Scott, F. K. Dolbeer, Edw. F. Swift and Rathbun Fuller.

Spacke to Produce Low Priced Car

INDIANAPOLIS, May 13—The Spacke Machine & Tool Co. will begin producing within the next four weeks a car which will be sold for $295. It will be known as the Spacke and its builders claim that it will go between 40 and 50 miles on a gallon of gasoline. The company expects to be able to turn out 30 of these cars a day, and if present plans are carried out over 10,000 will be produced during the coming year.

The car is a roadster, seating two persons, and is equipped with the Spacke 9-13 De Luxe twin cylinder air cooled engine. Fully equipped, the car will weigh about 700 pounds. It will have a wheelbase of 90 in. It will use tires 28x3 in., and will have demountable wire wheels. The seats will be of the bucket type, the body of pressed steel. Atwater-Kent ignition will be used with hand control on the dash.

The car is equipped with two speeds forward and one reverse in a planetary system. Camshaft drive with helical gears is fitted on the machine and the lubrication is of the eccentric pump and splash type. The gasoline feed of the car is gravity with a foot accelerator. The body will be painted a battleship gray.

The manufacture of the car will be confined to the present factory and a new assembly plant, while Factory No. 2 will continue to produce car axles.

General Motors Issues $50,000,000 Stock

PONTIAC, May 14—General Motors Corp. has issued $50,000,000 additional cumulative 6 per cent debenture stock to provide increased working capital. This brings the total outstanding up to $85,315,000. The amount authorized is $150,000,000.

Capt. Lepere President of the Franco American Engineering Co.

DETROIT, May 15—Capt. Georges Lepere, who came to this country in 1917 as chief engineer of the French aviation mission to America, is remaining as president of the Franco-American Engineering Co. here. Capt. Lepere is the designer of the Lepere fighting plane. The company is doing consulting engineering work on cars and engines as well as airplanes.

8-Hour Day Voted by French Parliament for All Industries

Involves No Wage Reduction but Increased Production—Agreement Already in Effect in Some Factories—General Satisfaction with Scheme

PARIS, April 26—The 8-hr. day voted by the French Parliament will affect the entire automobile industry of France. The engineering trades of France, however, had not waited for the Government decree before reducing the number of working hours to 8 per day.

Early in March the men's unions approached the French Union of Metal Industries and Mines with a view to the adoption of the 8-hr. day. The manufacturers declared their willingness to meet the representative of the workers, and although considerable difficulties had to be overcome a satisfactory agreement was arrived at for the entire metal industries of France, including mechanical construction, naval engineering, and electrical work. The men's delegates signed the agreement on behalf of 200,000 workers. Even among the socialistic element it is recognized that the manufacturers displayed a broad and generous spirit throughout the negotiations.

Production to Be Speeded Up

In the agreement between masters and men, it is recognized that there shall be a general speeding up by the adoption of more modern methods of shop practice, so that the output shall be the same under the 8-hr. day as under the old system. At the same time it is clearly understood that the reduction in the number of working hours shall not be accompanied by any reduction in wages. When men are paid by the hour there will be an increase in the rate, so that the same weekly salary can be earned.

The agreement went into effect 2 or 3 weeks before the law was passed. But even before this agreement, some of the automobile factories had adopted the 8-hr. day. One of the first to make this change was M. Laurent Seguin, head of the Rhone & Gnome Aviation & Automobile Co. Mr. Seguin was convinced that the 10-hr. day, 60-hr.-per-week system, in general use in France, was not economical. The men began work at 7 a. m. and left at 7 p. m. after having spent 2 hours over a heavy lunch. In winter work had to be done by artificial light at each end of the day, whilst 2 of the brightest hours of the day were spent in eating, or in going to and from the factory and home.

There was inefficiency at the beginning of the day, for the hour immediately following lunch, and during the last hour of the day. It was proposed that the men should work for 8 consecutive hours, with the exception of a break of one-half hour to take a light meal on the premises. This half hour is paid. The men now start work at 7.30 and quit at 3.30. Since this scheme was adopted by Rhone & Gnome it has been taken up by the Rolland-Pilain Automobile Co., at Tours.

This experiment is being watched with considerable interest. Officially it will not go into effect before June 1, 1919, but in many cases the 8-hr. day will be adopted immediately. In blast furnaces and other establishments where fires have to be kept going continuously, it will be necessary to modify the plant, and on this account the new régime will not be applied until 6 months after the signing of peace preliminaries.

In the agreement between masters and men, as well as in the Government law, provision is made for either 6 days at 8 hours each, or for what is known as the English week, under which the factory is closed on Saturday afternoons, the total working hours for the week not exceeding 48.

International Signals for Aircraft in Distress

LONDON, April 19—In a "Notice to Mariners," the Admiralty announces a provisionally agreed upon international code of distress signals for airplanes. The Board of Trade has also notified owners and masters of shipping. The announcement of the Air Ministry is as follows:

"In order to eliminate unnecessary risks of fatal accidents to aircraft and pilots, signals for aircraft in distress have provisionally been agreed upon by the International Aerial Sub-Committee of the Peace Conference in Paris and will be used in the future.

"The signals, which may be displayed by the aircraft, either together or separately, are as follows:

1. The International Signal "S.O.S." by means of visual or wireless telegraphy.
2. The International Code Signal of Distress indicated by N.C.
3. The Distance Signal, consisting of a square flag having above or below it a ball or anything resembling a ball.
4. The continuous sounding with any sound apparatus.
5. A Signal consisting of a succession of white Very Lights fired at short intervals.

"These signals are subject to such modifications as may be published from time to time."

Tire Prices Going Down

Reduction, Averaging About 15 Per Cent, Attributed to Plentiful Supply of Rubber

NEW YORK, May 12—Tire prices have been quite generally reduced, the average reduction amounting to approximately 15 per cent. Although it was expected that prices would eventually come down, it was not thought that the reduction would be made so soon, and the action has caused some surprise, particularly in view of the fact that late last week tire manufacturers stated that no reduction was looked for until June 1 or later. In fact some went so far as to offer reasons why the revision should be upward instead of downward.

Goodyear started the downward move, and was followed almost immediately by United States, Firestone, Goodrich and practically all of the other large makers. At this time there are very few makers who have not made public new lists with reductions ranging from 10 to 15 per cent, the average being approximately the larger figure.

The present reduction is laid largely to the plentiful supply of rubber, as well as to its low price. Last month a total of 24,000 tons came in as compared with a total of about 7000 tons the same month last year. Shipping is easing up to a noticeable degree and still better conditions are looked for in the immediate future.

The fabric situation is not in an altogether satisfactory condition. Since England placed an embargo on all Egyptian stocks, prices have soared and there is little, if any, available.

It is expected that some Egyptian stocks may be released soon, and this probably will cause a drop in fabric prices. The general tendency at present is toward a slight reduction. Factories are not buying in any quantities for future deliveries, most of them ordering only what they need and re-ordering as this is used up.

Chemicals, too, have been declining slightly, but against the reduction in costs of chemicals and fabric, there is the present high cost of labor. It is not expected that this will be reduced for some time to come.

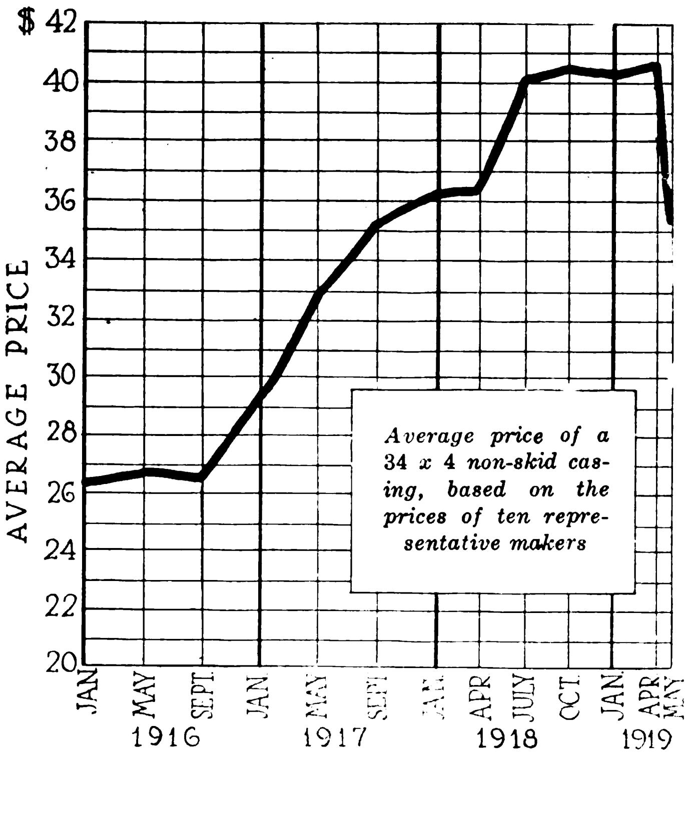
Tire prices have remained practically steady for nearly a year. The last general movement was an increase, this being made about April, 1918, when most makers added something like 10 per cent to their lists.

Prior to the present drop, prices had reached what is probably their record height. The average price of a 34 x 4 non-skid casing, considering the products of 10 of the leading manufacturers in all price-class fields, stood at $40.47.

Assuming that all manufacturers reduce their prices in accordance with the reductions made by the leaders, this average at the present time figures out at $35.43, which is very close to the average for September, 1917, as shown by the accompanying chart.

Tire prices first started on their upward trend in January, 1916, when most makers added approximately 10 per cent to their lists. A year prior to that, in February, 1915, makers had reduced prices by 10 to 15 per cent. The next rise came in December, 1916, when 15 per cent was tacked on; in April, 1917, another 15 per cent was added; in September, 1917, prices were raised from 5 to 15 per cent, this being the third increase in the year; and in April, 1918, another 10 per cent was added.

Just how long the present prices will hold it is difficult to predict. It is pointed out that crude has reached its lowest point for a number of years.



Average price of a 34 x 4 non-skid casing, based on the prices of ten representative makers

New Corporation to Take Over Red Head Spark Plugs

NEW YORK, May 10—The Red Head Spark Plug Corp. has been formed with principal sales offices at 261 Broadway, and has taken over the Red Head Spark Plug business formerly operated by the Emil Grossman Corp., Brooklyn, N. Y. The new company has no connection with the old one. It will continue and enlarge the business. An insulating plant has been opened at Newtown, Pa.

27,948 Tons of Rubber Imported in April

Figures Are 14,523 Tons Ahead of Same Month in 1918—Returning to Normal

NEW YORK, May 13—The removal of all government restrictions on the importation of crude rubber into the United States and the improved shipping facilities have combined to bring rubber imports back to normal. Figures for April show importation of 27,948 tons. The slight decrease from the 28,223 tons for March is undoubtedly explained by the irregularity of the shipping schedule at the present time. Figures compiled by the Rubber Association of America showing the importation figures for crude rubber for the past four years follow:

	1916 Tons	1917 Tons	1918 Tons	1919 Tons
January	9,162	12,788	16,084	7,235
February	1,597	10,162	13,108	14,079
March	10,070	18,624	17,161	28,223
April	10,014	13,000	13,425	27,948

Bulletin on Gasoline Issued by Bureau of Mines

WASHINGTON, May 13—Methods of analyzing and securing information of gasoline properties have been described in detail in a technical paper, Motor Gasoline Properties, Laboratory Methods of Testing, and Practical Specifications, by E. W. Dean, and issued by the Bureau of Mines, Department of the Interior, this week. The paper is an elaboration of an earlier paper on similar subjects.

The revision brings information up to date and includes methods of production, laboratory methods of analysis and outlines the principles upon which gasoline specifications should be based. The problem of writing specifications for gasoline is treated and specific recommendations are made regarding the limitations which are believed to be important. Figures specifying any particular grade of gasoline have not, however, been included, as it is believed by the Bureau that no single general specifications for motor fuel are either practical or desirable.

The properties and methods used for the analysis of gasoline are described in detail. Chief emphasis is laid upon the tests of greatest importance, such as distillation analysis, but in addition a description is included of most of the tests that are recommended or used either by the Bureau or by other organizations. Convenient forms for recording the results of analysis of gasoline are shown and the table is included for transforming Centigrade temperatures into Fahrenheit equivalents.

Wisconsin Axles to Have New Maker

OSHKOSH, May 12—The E. B. Hayes Machinery Corp., maker of Wisconsin axles, has been sold to the Wisconsin Parts Co., a new corporation capitalized

at $500,000. W. F. Rockwell, formerly vice-president in charge of engineering and production of the Torbensen Axle Co., Cleveland, is president and general manager of the new concern, and Louis Schriber, vice-president of the Old National Bank of Oshkosh, is treasurer. The Wisconsin Parts Co. will continue the manufacture of Wisconsin worm drive axles for trucks from 1- to 5-ton capacity. A tractor axle has also been designed and is in process of manufacture. The present capacity of the factory is 500 axles a month, and additions now being made will soon double the capacity.

—

Patterson Truck to Come from Los Angeles

DETROIT, May 12—J. Neil Patterson, Los Angeles, Cal., is in Detroit completing plans for the organization of a new company to manufacture trucks and trailers at Los Angeles. He was former president and is now vice-president of the Los Angeles Trailer Co.

The new company will bring out a truck to be known as the Patterson. It will be made of standard parts. It will have many new features to meet western conditions. Eastern as well as western capital is interested. Robert Fry of Detroit, until recently with the engineering department of the Motor Transport Division of the Army, is associated with Mr. Patterson as chief engineer.

—

Fellows Gear Shaper Extending Plant

SPRINGFIELD, VT., May 11—The Fellows Gear Shaper Co. will make further extensions to its plant, which was enlarged during 1918. A 2-story shop, 144 x 147, of brick and steel, will give an increased manufacturing capacity of 60 per cent. When the additional plant is in full operation, the 450 men now employed will be increased to 750. An office 42 x 102 will also be built. The top floor of the new office building will be occupied by the engineering and drafting departments, and the general offices will be on the second floor. It is estimated that the extension will cost about $200,000, not including equipment.

Overland Strike Is Still On

Manufacturers Siding with Overland Rousing Organized Labor —Workers Want 44-Hr. Week

TOLEDO, May 13—Rioting late Wednesday and Thursday afternoons at the plant of the Willys-Overland Co. caused Clarence A. Earl, vice-president and general manager, to order the plant closed indefinitely, making approximately 16,000 men idle. In issuing the order, Mr. Earl stated that he was closing the plant as the only way of averting bloodshed.

The Electric Auto-Lite Co. and the Ford Plate Glass Co. are also closed. Although the Willys-Overland Co. and a committee of Overland employees have been holding daily conferences since Saturday, no perceptible progress in adjusting the trouble has been made.

A new and grave crisis is developing which may involve the entire industrial section of Toledo. In a signed statement, published in all the Toledo papers, nearly 100 Toledo manufacturers endorsed the stand of the Willys-Overland Co. This statement has aroused organized labor to a high pitch and talk of a general strike is heard everywhere.

Mayor Schreiber is acting as the point of contact between the strikers and the company. His request that he be permitted to assist in bringing about a settlement was accepted by both parties. More than 7000 workers, at a mass meeting Friday, agreed to appoint a subcommittee to accompany the mayor to the Overland plant.

From the tone of the newspaper articles it is apparent that Toledo is badly split in its opinion as to justifiability of the strike. A big element is endorsing the stand of the company. The only point in question is the matter of hours. The workers are willing to stay on the job 8 hr. and 36 min. daily if they receive overtime for the extra 36 min. The company is steadfast in its determination to operate on a regular schedule of 48 hours a week without the overtime. It is on this point that the whole strike is based.

Governor Cox of Ohio has ordered George F. Miles, chief investigator of the Industrial Commission, to Toledo, to aid in bringing about a settlement. The police department has taken steps to deputize 3000 special officers to keep order in and about the plant.

—

National Organization for Liberty Highway

SPRINGFIELD, ILL., May 13—At its first annual convention held recently a national organization of the Liberty Highway Association was effected. Stephen Lawless, Liberty, Ill., was elected president and Truman T. Pierson, Quincy, Ill., treasurer and national organizer. Vice-presidents are: R. J. Holmes, Decatur, Ill.; C. A. Hetrick, Asbury Park, N. J.; Joseph T. Daniels, Columbus, O.; George A. Binkert, Quincy, Ill., and W. H. Conkling, Springfield, Ill. The organization has been formed for the purpose of having a hard surfaced highway built across the continent from ocean to ocean.

—

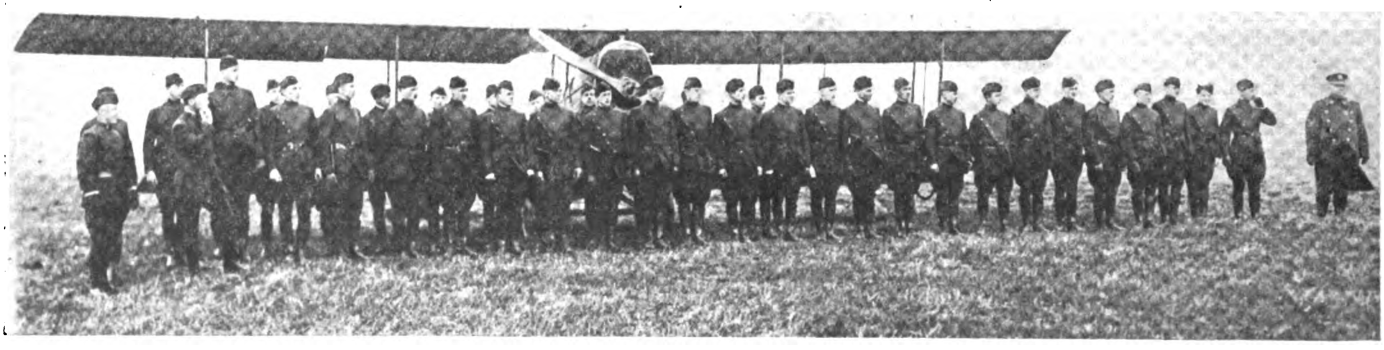
Dependable Truck to Move to Peoria

GALESBURG, ILL., May 11—The Dependable Truck and Tractor Co. is considering the removal of its plant and headquarters to Peoria. Plans have been completed for a building with 50,000 sq. ft. of floor space. C. W. Morse, who is at the head of the company, was formerly with the Locomobile Co. of America and later with the Pan-American Corp., Decatur, Ill.

—

Eisemann on Overtime Basis

BROOKLYN, May 14—The steady drift toward normal conditions in the motor industry, following the change of conditions due to the termination of the war, still finds the Eisemann Magneto Co. working full blast, with part overtime. The indications are that in order to maintain its record for prompt deliveries on its large bulk of commercial orders the entire Eisemann plant will be working to its capacity for some time to come.



Inauguration ceremony of Pioneer Wing of Police Reserve Air Service, making New York the first municipality with aerial police force. Two Curtiss JN-4D biplanes with 110-hp. engines were used at inauguration ceremonies. First flight was made to Philadelphia

Cheap Roads Increase Transportation Cost

National Highway Traffic Assn. Hears Practical Problems Discussed at First Annual Meeting

NEW YORK CITY, May 14—Upward of 75 attended the first annual meeting of the National Highway Traffic Association, an organization formed last November for the purpose of working for traffic betterment throughout the country. This organization had its inception several years ago as a local traffic organization for greater New York City. It was soon expanded into a traffic organization for the state of New York. The demands for solution of traffic problems from adjoining states suggested the desirability of making it a national organization and this was successfully carried out. The membership is now over 300.

Development of Rural Express

The subjects considered at yesterday's meeting had to do with the development of rural motor express. F. W. Fenn of the National Automobile Chamber of Commerce gave a complete summary of what has been accomplished throughout the country. J. H. Collins, Highway Transport Committee, Washington, outlined the necessary plans for making surveys for rural motor express routes, and James E. Boyle, professor of rural economy at Cornell University, analyzed the situation in New York state. He showed the fluctuating costs of farm products in different seasons due to lack of flexibility in highway transportation.

H. G. Shirley, secretary of the Federal Highway Council, Washington, referring to the work of the council, reported that it has 400 members and its work has been endorsed by 800 commercial organizations. The national character of the Federal Highway Council's activity is indicated by the fact that 43 state highway departments are now co-operating with the council and 68 different highway officials are represented in the council.

Road Cost

Geo. H. Pride, president of the Heavy Haulage Co., New York, an organization engaged exclusively in motor transportation between cities and in practically any field, declared that heavier loads must be permitted on the highways if cheaper transportation is to be obtained. He says it is possible to make money on inter-city haulage between New York and Boston if you are permitted to carry 7½-ton loads, but is not possible with 3 or 5-ton loads. His views on the problem of road cost are very practical. If expensive highways that will withstand heavy traffic are built the cost of transportation is lowered; but if cheaper highways are built that will not carry heavy traffic, the cost of transportation is increased. It is a case of six of one and half a dozen of the other. If you do not pay the bill in road-building you pay it in higher cost of transportation, and vice versa. In either case it is the general public that pays the bill.

First Aeronautical Exposition for Holland

WASHINGTON, May 14—During July and August an International Aeronautical Exposition will be held at Amsterdam, Holland, under the auspices of the Chambers of Commerce of Amsterdam and Rotterdam, the secretaries of the Interior, War, Agriculture, Commerce and Water Works, the governor of the province of North Holland and the chairman of the Royal Dutch Association of Aircraft. Foreign airplane industries will also take part.

The exposition will include aircraft and all aids to air transportation, but aircraft designed primarily for military use will be excluded. The motor industry will be represented as will parts and accessories. Demonstrations and air contests will also form part of the program.

Exhibits will be accepted commencing June 15. Further information can be procured from the commercial attaché of the Royal Netherland Legation, Washington, D. C.

U. S. Rubber Offers Common Stock to Employees at $70

NEW YORK, May 15—Employees of the United States Rubber Co. have been offered the chance to purchase common stock of the company at $70 a share. It is now selling on the market for $95. Employees will be given 5 years in which to pay for subscriptions.

Square Turn Tractor Elects Officers

NORFOLK, NEBR., May 12—New officers elected by the Square Turn Tractor Co. are: President and general manager, R. Florian; vice-president, G. S. Albaugh; vice-president, C. E. Burnham; treasurer and secretary, William G. Eppley; production manager, F. E. Wilson; sales manager, F. H. Squires; chief engineer, A. J. Colwell.

Claudel Carbureter in American Production

NEW YORK, May 15—The Claudel carbureter, patented in France in 1902, will be produced in America by E. J. Conill and Israel Ludlow. Offices here are in the Aeolian Building. The Detroit branch will be in the Garfield Building in charge of Frank R. Jackson, for many years with the Zenith Carbureter Co.

A. H. Doolittle, sales manager of the Zenith Carbureter Co. for several years, and lately general manager of the Sunderman Carbureter Corp., will be general manager.

Internat'l Harvester Makes $14,985,325

Statement for Year Combines Two Merged Companies—Effects of War

CHICAGO, May 14—The International Harvester Co., which is the company formed by the merging of the International Harvester Co. of New Jersey and the International Harvester Corp., shows an increase of $2,326,000 in its profits for 1918 over the combined profits of the two companies in 1917. A considerable part of the earnings came from the company's steel business, sales of motor trucks and government contracts.

Following is the complete balance sheet of the International Harvester Co. of New Jersey and the International Harvester Corp. combined for 1917, and the balance sheet of the merged companies into the present International Harvester Co. for the year ended Dec. 31, 1918:

ASSETS

	1918	1917
Property account, plant, mines and timber land, etc.	$65,694,250	$62,510,405
Inventories	114,516,302	78,682,825
Notes and accounts receivable	35,800,926	40,860,374
Fire insurance fund	1,258,950	1,258,950
Pension fund	1,000,000	....
Cash	28,040,060	35,258,327
Deferred charges	335,934	149,481
Investments	11,737,597	15,191,670
Funds withheld in Europe by war conditions	24,834,972	35,312,972
Total	$283,218,991	$269,225,004

LIABILITIES

	1918	1917
Preferred stock	$60,000,000	$60,000,000
Common stock	80,000,000	80,000,000
Bills payable	10,370,000	12,784,300
Accounts payable	35,882,912	29,052,928
Reserves	26,679,417	24,786,438
Preferred dividend payable	1,050,000	1,050,000
Common dividend payable	1,200,000	500,000
Surplus	68,036,662	61,051,338
Total	$283,218,991	$269,225,004
Profit	$14,985,325	$12,560,315

The 8-hr. day was made effective by the International Harvester Co. in all Amercan plants during the year and the wage increases have brought the present hourly wages 100 per cent above those of 1914. The French factory near Lille is being re-equipped after being stripped of all machinery and material by the Germans. The factory at Neuss, Germany, is under the jurisdiction of the allied army of occupation. The Russian factory near Moscow was running at last reports, but all American employees were forced to leave by the end of 1918. A few of the Russian branch houses are still in operation, but most have been

closed. To meet the depreciation of the Russian investment, $24,205,000 was charged off in the past two years. The Harvester industrial council adopted in March is now in operation in 19 of its 20 plants in the United States and Canada.

—

Government to Buy Airplanes

WASHINGTON, May 14—Plans of the Army Air Service are for the purchase of about 500 airplanes of the approved army types. Contracts have been prepared and sent to Secretary Baker for his consideration. The primary purpose is to keep the industry in sufficiently active condition to insure rapid expansion in case of emergency.

The seven types of planes approved by the Air Service, and which will probably be purchased, include the Le Pere observation, the Hoening monoplane, the Thomas Morse scout, the US-D 9-A day bomber, the Voight training plane, the Martin day bomber and the ordnance engineer pursuit plane. With the exception of the Voight, all of these types were developed in the United States during the war.

The Air Service also plans to further encourage the airplane industry by recommending that the War Department and other government agencies lend domestic manufacturers their assistance to develop markets for airplanes in South and Central America.

—

New Road Work Records Made in April

WASHINGTON, May 15—During April, 1919, the Secretary of Agriculture approved project statements for 120 Federal aid projects, involving the improvement of 923.53 miles of road at a total estimated cost of $16,261,326.51, and on which Federal aid in the amount of $7,528,550.68 was requested. This represents the largest number of project statements approved, the largest total estimated cost, and the greatest amount of Federal aid requested during any month since the passage of the Federal Aid Road Act in March, 1919, which surpassed all records in these items up to that month.

During April 55 road projects were approved and executed involving the improvement of 521.51 miles of road at a total estimated cost of $4,626,415.48, and on which $2,039,614.99 Federal aid was requested and set aside in the Treasury. In addition, agreements to cover 72 other projects were placed in process of execution during the month.

Up to and including April 30, 1919, statements for a total of 1057 projects had been approved, after deducting all approved projects cancelled or withdrawn by state highway departments. The 1057 projects involved 10,580.17 miles of road, a total estimated cost of $92,933,-121.81, and a total of $36,576,857.48 Federal aid. On the same date a total of 535 project agreements had been executed, involving 4,624.83 miles of road, a total estimated cost of $39,059,327.44, and a total of $15,614,929.61 Federal aid.

Reservations Coming Fast for S. A. E. Summer Meeting

NEW YORK CITY, May 15—Reservations for the summer meeting of the Society of Automotive Engineers to be held at Ottawa Beach, Lake Michigan, June 23-27, are coming in at the rate of 40 to 50 per day. Reservations with checks have been received from 250, and promises are that the hotel capacity will be sold out by June 1 or soon after.

It would be almost impossible to find a summer hotel better suited for such a convention. The exclusive use of the hotel for the period of the convention will enable the members to get better acquainted, and to talk over matters relating to engineering that they have not had an opportunity to do since the war. The professional program is being so arranged that approximately 50 per cent of the time will be free for discussion of papers and addresses. Instead of having two sessions per day, one in the forenoon and one in the afternoon, there will be an extra long morning session and no sessions in the afternoon.

A new feature of the meeting will be hour lectures each evening after dinner and before the dancing starts at 9 o'clock. These lectures are to be on popular subjects, some related to engineering and others not.

Arrangements are being made for the entertainment of the women. Forenoon lectures by important women outside of the society are being arranged. There will be various amusements, sport tournaments, and other diversions.

—

Curtiss Seeks Injunction for Commercial Sale of Government Planes

BUFFALO, May 14—The Curtiss Aeroplane & Motor Corp. has begun suit in the United States Court to restrain the United Aircraft Engineering Corp. from selling airplanes purchased from the British government in Canada to buyers in the United States. The Curtiss company alleges that the sale of these planes would be an infringement on 13 patents which it owns, some of them controlling and others covering certain structural features of the planes. The bill states that the planes were manufactured by the British government in Canada under rights granted by the Curtiss company on condition that they were to be used only for war purposes, that is, for training in Canada only.

—

Building Back to Commercial Work

BOSTON, May 14—The Ford Motor Co. building in Cambridge, which was turned over to the Quartermaster Department early in the war, was returned this week to its owner. Since the beginning of the war the Ford building has been the chief quartermaster store for the Boston district and a vast quantity of army supplies have been shipped from there. Considerable readjusting will be necessary before the building is ready for the assembly of cars. The offices on Brookline Avenue have been moved back to Cambridge.

—

All Air Pilots Must Be Licensed

WASHINGTON, May 10—All civilians who pilot aircraft, including seaplanes, airplanes and balloons, must obtain licenses from the joint Army and Navy Board of Aeronautic Cognizance. A heavy fine is attached to operation without license. Application can be made to Lieut. A. J. Clayton, Building D, Sixth and B streets, Washington, D. C.

—

May Buy More Hispanos

NEW YORK, May 15—It is reported that the Government shortly may place orders with the Wright-Martin Co. for a quantity of Hispano-Suiza engines. It is stated that the order may amount to $5,000,000.

—

Lauraine Magneto for Long Island City

LONG ISLAND CITY, May 14—The Lauraine Magneto Co. is building a factory here and will move its machinery from its Menominee, Wis., plant to the new building shortly. The new structure is 150 x 100 ft., giving a floor space of 15,000 sq. ft., and having a capacity for 50,000 magnetos in 1919. Plans call for doubling production facilities next year, giving an output of 100,000.

—

Stevens Named Rex Vice-President

PONTIAC, May 14—Guy N. Stevens, assistant secretary of the Olympian Motors Co., has just resigned, to become vice-president and treasurer of the Rex Tool & Machine Co. He is also assistant secretary of the Power Truck & Tractor Co., Detroit.

—

French Tractor Design

(*Continued from page* 1049)

is a very compact machine with engine forward, engine base and gearbox in one casting, and drive taken to all four wheels. The machine has four speeds, two of which are calculated for use in the field, and two when the tractor is employed on the road.

The Gnome & Rhone machine is marketed under the title of the Aurore. It is being sold at $2,400, which is a very low price compared with other and similar machines shown at the demonstrations. One of its features is the use of a detachable strake of a very simple and practical nature. This is in three sections for the entire circumference of the wheel, and is attached to the latter by means of lugs in the inner face which pass through holes on the wheel rim and are then secured by a bolt. The entire set can be fitted in five minutes and taken off in less tha ntwo minutes.

—

Erie Tire Ready for Production

SANDUSKY, OHIO, May 9—The Erie Tire & Rubber Co. will begin manufacture about Aug. 1. The company will specialize in cord tires and tubes. It is organized under the laws of Ohio with

an authorized capital stock of $1,000,000, half of which is 7 per cent cumulative stock and half common stock. The officers are: President, C. H. Berlekamp; vice-president, H. H. Forest; treasurer and general manager, P. F. Wills; secretary, C. H. Roth.

—

Advance in Steel Plates

NEW YORK, May 14—The Lukens Iron & Steel Co. is the first to raise the price of steel since a free market was created by the abandonment of the stabilization plan by the government and the industry. It has raised the price of steel plate $2 a ton. Although this is the first move toward an increase in steel there is a general feeling in the industry that it is a forerunner of a general rise in prices.

—

Appleton Engine Works in New Building

APPLETON, WIS., May 10—The Appleton Engine Works has purchased a vacant building at 1019 College Avenue and after remodeling and enlarging the structure will transfer its entire operations to the new location. The capacity will be increased threefold when the improvements are completed June 15.

—

Young Industries Buys Factory in Jackson

DETROIT, May 10—L. A. Young Industries, Inc., has purchased the factory of the Borden Mills Co., Jackson, Mich., with 150,000 sq. ft. of floor space, and will announce shortly the purchase of another plant in the state. Both of these factories will be operated as part of the wire division of the company, and men and machinery will be removed from Detroit to operate them.

Ford Planning Foreign Production

Factories for Italy, France, Russia and Germany—Assembly Plants for Smaller Countries

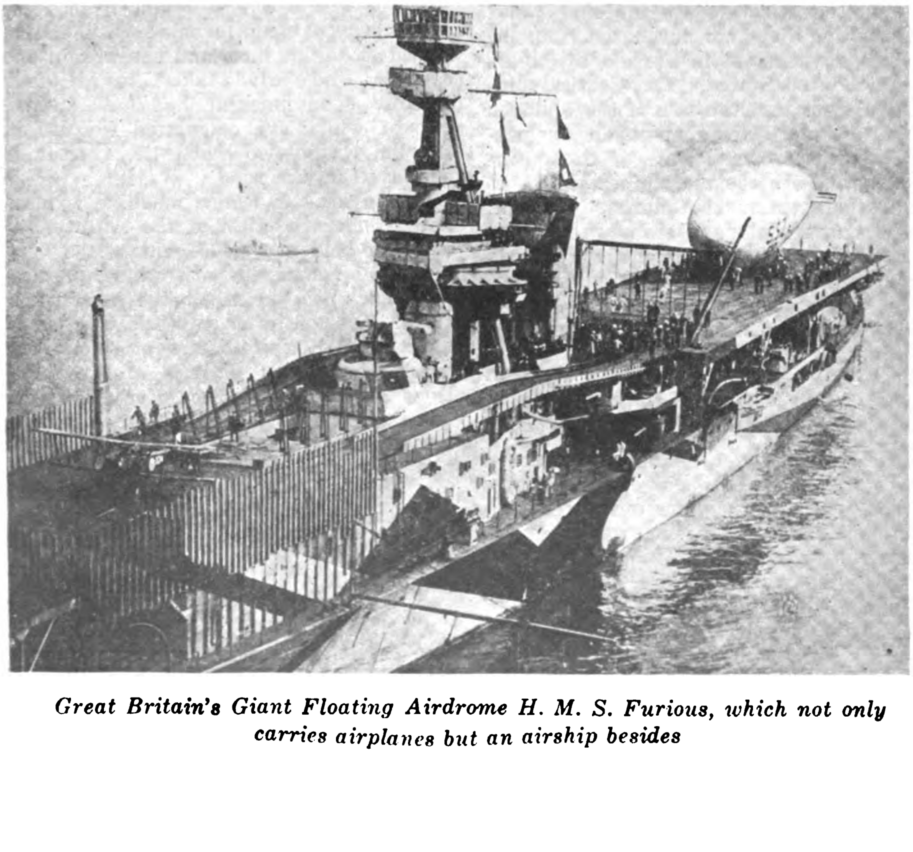
DETROIT, May 12—Ford Motor Co. officials state that as soon as the peace treaty is signed, immediate steps will be taken for building several assembly plants in European countries, besides factories in many of the foreign nations such as Italy, France, Germany and Russia. In the smaller countries such as Denmark, Spain and Portugal, assembly plants will be erected with an average capacity of 100 cars per day. These latter plants will be the first constructed and will become the clearing houses for the parts supplied to them from the Detroit and Manchester, England, factories. Cadiz and Copenhagen have already been decided upon as cities where assembly plants will be erected, each to cost approximately $350,000.

By this system the Ford interests expect to be able to place on the European market at least half a million cars annually. It is but a question of weeks when the Paris and Bordeaux offices of the company will be re-opened.

Ford officials will not deny that the present sites decided upon for tractor plants are Troy, N. Y., and Pennsgrove, N. J., and that the Troy plant will also manufacture the standard Ford car.

At the Ford plant, figures obtained show that from April 28 to May 6 inclusive, 21,761 cars were manufactured, being a daily average of 2720. The most productive day during this 8-day period was April 29, which shows a total output of 3312, and May 1 the smallest output, 2651. For the month of April, which contained 26 working days, the plant's output totaled 69,947, a daily average of 2689. The actual number of unfilled orders April 20 was 80,283, which was increased to 88,528 on May 8.

Ford officials are confident that, beginning June 1, the daily average output will be 4000, and that the number for the present year will exceed 1,000,000. This enormous output of cars requires the services of approximately 40,000 men. The number now on the Ford payroll, which includes the car, shipbuilding, blast furnace and carbureter plants, is 53,650.



Great Britain's Giant Floating Airdrome H. M. S. Furious, which not only carries airplanes but an airship besides

Fordson Production After Inventory

DETROIT, May 12—The Fordson Tractor plant at Dearborn is starting production again after a 15-day suspension of operations for inventory. While it may be two or three weeks before the company gets into full production, operations started this week with a fairly large force. The company found that it was overstocked with certain materials and to bring conditions to a balance again, operations are being pushed in the over-stocked departments and curtailed in those where conditions are normal.

—

General Motors Discloses Further Plans

DETROIT, May 9—Plans for the development of the General Motors property on both sides of Holbrook Avenue have been disclosed with the application of the General Motors Corp. to the city council for permission to run two sidetracks across Holbrook Avenue. This tract will contain an engine plant, differential gear plant, a die shop, heat-treating plant, forge shop of the Central Forge Co., and an axle plant. Later a large truck assembly plant will be erected. The land comprises nearly 60 acres. The new plant of the Cadillac Motor Car Co., Detroit, has been planned for the old American Car & Foundry site on Scotten Avenue and will be one of the largest of the General Motors projects.

War Contracts Reduced from $5,600,000,000 to $500,000,000

WASHINGTON, May 12—More than 90 per cent of the war contracts placed and outstanding on Nov. 9, 1918, have been completed either by termination or delivery, being reduced from $5,600,000,000 to $500,000,000. Cancellations and suspensions reported for the two weeks ended April 12 totalled $70,000,000, and delivered $50,000,000. Following is the status of cancellations on April 12 of the air and motor contracts:

	Bureau of Aircraft Production	Motors and Vehicles
Contracts outstanding Nov. 9, 1918a	$672,849	$441,691
Reductions since Nov. 9, 1918, by termination	498,039	294,288
By deliveries	160,000b	126,827
Remaining outstanding	14,810b	20,626

(a) Some items include subsequent commitments.
(b) Estimated; subject to revision.

Petroleum Products for February

Production Decreased Slightly But Stocks Are Satisfactory and Position Is Good

PRODUCTION

	February, 1919	January, 1919
Crude oil (bbl.)	25,232,876	26,967,332
Gasoline (gal.)	283,518,194	303,710,556

STOCKS ON HAND

	Feb. 28, 1919	Jan. 31, 1919
Crude oil (bbl.)	14,820,601	15,380,185
Oils purchased to be re-run (bbl.)	1,176,483	1,088,264
Gasoline (gal.)	458,449 187	383,212,692
Kerosene (gal.)	303,062,436	332,393,181
Gas and fuel (gal.)	692,816,000	646,411,414
Lubricating (gal.)	152,297,163	158,370,431
Wax (lb.)	209,908,707	189,064,329
Coke (ton)	33,716	28,732
Asphaltum (ton)	102,547	93 027
Miscellaneous (gal.)	500,413,825	483,942,833

WASHINGTON, May 14—Although production of both crude oil and gasoline shows a slight decrease over January figures, stocks of gasoline and fuel oil on hand show an increase, marking the tendency to catch up with production to some extent. At the present time the stock of gasoline on hand is 75,236,495 gal. more than it was in January and there are 46,404,586 gal. more fuel oil on hand.

Almost all through 1918 the consumption of petroleum products exceeded the production. It was almost the end of December before the production was in excess of consumption. In January, 1919, both production and consumption dropped to some extent. However, consumption dropped to a greater extent than production, thus improving the general situation.

During February the position continued to improve, and a curve showing the situation would indicate that production for the month was decidedly above consumption. Obviously consumption, so far as use by passenger cars is concerned, was at a low point in February, as in other winter months, but road transport by truck has been on the increase and was maintained throughout the winter on a larger scale than heretofore.

N. A. C. C. Will Fight Chassis Tax

WASHINGTON, May 13—The National Automobile Chamber of Commerce has filed a protest with the Treasury Department against the rulings on the tax for chassis. Under the present ruling, if a manufacturer sells a chassis directly to a consumer there is one tax of 5 per cent paid. If a manufacturer sells a chassis to a dealer there is no tax paid by the manufacturer if the dealer knows for what purpose it will be used, and fills out certain necessary papers. If, however, the dealer is unable to definitely specify how the chassis will be used, by whom, etc., the manufacturer pays a tax of 5 per cent.

If the manufacturer sells the chassis to a distributer and he in turn sells to a dealer both pay a tax. If a dealer sells a chassis he pays no tax unless he attaches a body to it, when it is regarded as a manufactured vehicle and again becomes subject to taxation, 3 per cent for a truck and 5 per cent for a passenger car. It is expected that there will be some time required before the tax department will give a new ruling on this.

P. T. Tractor Wheel Acquired by Wm. Wharton

EASTON, PA., May 14—The Wm. Wharton Jr. Co., associated with the Trylor-Wharton Iron & Steel Co., has acquired the patent rights and will manufacture the P. T. wheel for tractors and trucks. The P. T. wheel, originally an Italian invention, was formerly made in the United States by the P. & T. Wheel Corp., Dayton, Ohio. A complete description of it appeared in a former issue of AUTOMOTIVE INDUSTRIES.

Building Factory for Transport Truck

MT. PLEASANT, MICH., May 10—Work on the new plant of the Transport Truck Co. has commenced. The buildings will cost $150,000 and will be ready for operation before the end of the year. The officers of the company are: President, M. A. Holmes; vice-president, H. E. Chatterton; secretary, W. D. Hood, and treasurer, A. E. Gorham. The capital stock of $1,000,000 is half paid in. At the company's present quarters two models are being built, a 1½-ton and a 2-ton truck. When the company gets into its new factory two more models will be built.

50% Detroit's Contract Claims Approved

92 Per Cent Filed—70 Per Cent Aircraft Claims Recorded—Problems of Settlement

DETROIT, May 12—Greater progress has been made in this district by the Government Claim Adjustment Board during the past 30 days than at any other time since the organizations were established to aid the war contractors in getting settlements of war contracts. Approximately 92 per cent of a total of 236 claims have been filed with the Ordnance Claim Board. The total value of these contracts now up for settlement or already settled at Washington is approximately $25,000,000. The percentage of claims approved at Washington is about 50 per cent.

40 Per Cent of Aircraft Claims Approved

During the last two weeks things have not moved as fast with the Aircraft Board as with the Ordnance organization. All of the big aircraft claims are still out and may not be filed for some time. Approximately 40 per cent of the total of aircraft claims in this district have been approved at Washington. Thirty per cent are now before the board and 30 per cent remain to be filed. Officials of both boards, however, predict that settlement matters will move rapidly from now on. Many points which have been holding back claims have been cleared up at Washington and new regulations are greatly simplifying the work of the board.

Claims officials declare they have received no information from Washington relative to the suspension of work May 15. They look upon the publicity sent out by the Secretary of War's office calling attention of contractors to the necessity of filing their claims before May 15 or seeking redress elsewhere as a rather crude method of stirring the contractors into action. There is no question, however, but what this publicity has had a marked effect, as more claims have been filed within the last two months than during any other period. All boards will continue to function as in the past until

orders bringing work to a stop are issued at Washington.

While contract settlement delays caused many local concerns financial embarrassment, no real hardships resulted except in a few isolated cases. Four firms agreed to a 75 per cent settlement in order to get immediate cash, leaving the remaining 25 per cent to be settled later when the government completes checking up invoices and claims.

It was not until March 2 that Congress passed the law permitting settlement of informal contracts by validating them. Until the Dent bill became a law, the adjustment boards were limited to action on formal contract claims only. Inasmuch as more than two-thirds of all war claims in this district were of an informal nature, the majority of the work of both boards was held up, awaiting congressional action.

The greatest problem of settlement resulted from the action of the government in shifting all contracts from a fixed price basis to a cost plus 10 per cent basis. This caused all companies affected to make radical changes in their manufacturing plans. There are companies who will be heavy losers as a result. For instance, a certain automobile company contracting for the manufacture of shells at a fixed price carries a large portion of its employees on its regular automobile payroll contemplating a big profit on shell manufacture by cutting overhead to a minimum. It filed with the government a cost estimate on the price of shell manufacture according to that plan. When the government automatically switched contracts to a cost plus 10 per cent basis, the company having already gone upon record regarding shell production costs, was obliged to start up its munition work as separate departments, hiring additional men and conducting the work at excessive expense if not actual loss. There are others in the same fix, it is said.

All contract adjustment boards say it will be along in July before the last claims have been filed and settled.

Pan American Convention

WASHINGTON, May 12—The Pan American Convention, which will be attended by delegates from various industries of the United States and representatives from the Pan American countries, will be held in Washington, June 3-6, at the Pan American Building.

Detroit Will Hold Prosperity Dinner

DETROIT, May 10—The May meeting of the Detroit Section of the Society of Automotive Engineers will be preceded by a prosperity dinner to be held at the Hotel Pontchartrain. The meeting will take place on May 23 and the dinner is scheduled for 6 p. m.

At the meeting held immediately after the dinner, Prof. W. T. Fishleigh of the University of Michigan will talk on "An Automotive Nation Victorious, and Its Prime Demands Upon Manufacturers, Engineers and Educators." The banquet speaker will be announced later.

Stagnation in British Car Industry

Production Small and Prices High—Used Car Prices Soaring—Buyers Offer Premiums

LONDON, ENGLAND, May 1—Uncertain conditions in the automobile industry, and a stronger spirit of procrastination than has been seen since the first of the year, continues.

In Coventry, which is one of the big centers, there is a dominating spirit of comparative stagnation in the industry. No one as yet seems to have gotten under way. Some makers are blaming labor. There are intimations that the salvation of the British motor industry rests in the influx of new blood into many of the older organizations. There are three or four firms coming into the industry from other branches of engineering and these have the necessary capital and apparently the proper spirit of progress.

There is a big amalgamation coming through in the automobile industry which points to the fusion of the Armstrong-Whitworth Co. and the Siddeley-Deasy Co. The latter firm is one that has made great progress during the war. In 1914 it had 3 acres of factory and now has 25. Siddeley-Deasy is one of the first to plan a low-priced car.

There still seems to be too much of the "getting it while the getting is good" spirit among car manufacturers, and prices are exceptionally high, as indicated by a 12 hp. car listing at $3500. There is no tendency to reduce prices, and naturally with comparative stagnation through the industry there is a shortage of cars. The private owner is faced with the fact that a car which sold for $1500 two years ago is now selling at $2500.

Production which was promised by the factories a month or so ago is not coming through. There are many deposits up on these cars and the buyers are awakening to the fact that when their deposit was taken the manufacturer must have been conscious of the fact that he could not make deliveries for many months. It seemed as if the manufacturer did not understand the situation well enough, and was not willing to go ahead with the production until he had orders and deposits placed with him. This points to the program followed by so many manufacturers in pre-war Olympia shows.

Production on a few of the lighter type cars is coming through. With high priced cars the production is so small as not to have any modifying effect on the market. Fine weather has spurred the buyer and the pernicious practice of offering premiums is making itself known. In one case a premium of $500 over the new price was offered on delivery on a 10-hp. car if the owner could have it by Easter.

As a result of holding back in the production of new cars the price of used cars is still increasing. Recently a 1913 French car was purchased for $650 and was sold a week later for $1750. This is not an exception and almost every day sees the value of used cars mounting in this way. There are 1914 Rolls-Royce touring cars selling at $10,000. Four years ago these cars were selling at $5,000 each. In 1915 a 15 hp. Renault limousine listed at $1560, but is now priced at $7500. Wolseley cars which 4 years ago listed at $2250 are now offered at $4500. These examples are typical of the increased prices of used cars.

British Import Restrictions Not Satisfactory to Importers

LONDON, ENGLAND, May 1—British importers are still of the opinion that the permitting of imports of American automobiles under the recent ruling of the Board of Trade is scarcely satisfactory to a minority of the importers, and that after September 1, when the matter is revised by the Board of Trade, some more satisfactory arrangement will be worked out.

The present ruling which permits of importing approximately 1200 automobiles in that period is a mere ration of the requirements, as there are some importers who have capacity for disposing of 6000 cars per year.

There has not as yet been an official interpretation of the 50 per cent ruling on imports, but one is to be issued shortly. There is a feeling that the concession for 50 per cent importation granted by the Board of Trade is open to a more favorable interpretation than that given. The action of the Board of Trade is awaited in clarifying this interpretation.

There have been some recent removals of import restrictions made by the Board of Trade as follows:

A—Prohibition of magnetos is to be maintained and licenses to import magnetos are to be granted only in very exceptional cases. This points to a certainty of the British magneto industry, which is a product of the war, being protected during the restriction period.

B—Forgings and castings for motor vehicles are to be prohibited and importation only under licenses.

C—The importation of clocks, clock parts, and clock movements is to be restricted to 50 per cent of the 1913 imports from all sources, importers obtaining their quotas from any country with which trading is permitted.

Lifts Ban on Passports for Business

WASHINGTON, May 12—The State Department will issue passports to all applicants who are going abroad on bona fide business, and American business men will be given every aid to carry on and develop foreign trade.

Import Certificate Number No Longer Necessary

WASHINGTON, May 10—It is no longer necessary for exporters to submit with their applications for licenses to export to Luxemburg and that part of the Rhine provinces occupied by the American and allied armies the number of the import certificate issued by the

Inter-Allied Economic Committee at Luxemburg. The War Trade Board has announced this amendment to the rulings made by it March 6, 1919. Applications for export licenses should be filed with the War Trade Board on Form X-A.

Manufacturers and Government Will Meet to Discuss Exports

WASHINGTON, May 12—A meeting to discuss existing embargoes and foreign trade restrictions, and their effects on the motor industry, will be held here soon. Automobile manufacturers and the Departments of State and Commerce will attend. The meeting was planned for this week, but was postponed. It will probably be held the first week in June owing to the inability of some of the manufacturers to get to Washington sooner.

Freight Rates for Trucks to Be Studied

WASHINGTON, May 10—A study of existing railroad freight rates and motor freight rates will be made by Capt. A. J. Stevens, assigned from the Department of Purchase, Traffic and Storage, War Department, to the Highways Transport Committee, National Council of Defense, for the purpose of fixing equitable and profitable rates by which motor trucks can haul commodities over rural routes. Existing rates, it is said, are neither equitable nor profitable, and many motor truck fleet owners are losing money in some instances and overcharging in others. It is to overcome these problems and to establish motor truck rural express on a sound basis that the work is being undertaken.

Steel Disk Wheels Wanted for Light Trucks

WASHINGTON, May 12—Orders will be placed for 550 steel disk wheels to take 38 x 7 pneumatic tires with straight sides. The wheels are to fit on the hubs of the rear wheels of the light aviation army trucks which have been taken over by the Post Office Department from the War Department. They are to be interchangeable with the wheels now on the trucks. A hub cap, locking flange, necessary clamping nuts and cap screws are to be furnished with each wheel. Prices are to be f.o.b. factory, and bids must include time of delivery. All bids should be sent to the Purchasing Agent, Post Office Department, Washington, D. C.

Tractor Demonstrations for Pennsylvania

HARRISBURG, May 10—The state of Pennsylvania is to hold four 2-day tractor demonstrations during the coming season. These will be held in different sections of the State. Representatives of various tractor companies have agreed on this schedule. There is a little uncertainty regarding the rules covering these demonstrations. Some of the tractor makers want to furnish their own rules and the State Department feels that it should have a voice in framing them.

Present Planes Lack Quantity Idea

Must Come Around to Ingersoll Type, Says Stout at S. A. E. Meeting—Other Subjects Discusssed

CHICAGO, May 9—Before we can call the airplane commercially successful we must go from the Swiss watch type of construction to an Ingersoll watch type. That is, we must make our future planes of more rigid construction on a quantity basis, and correspondingly cheaper. This was the capital idea in the talk presented to the Midwest Section of the Society of Automotive Engineers this evening by William B. Stout of the United Aircraft Corp., New York City.

In his talk on aviation, Mr. Stout said that aviation is a new lure, and those men who have been up in the air, who have been flying, and who for the moment are satiated with air work, are coming back with a craving for space. In judging the airplane of to-day we must hark back to the corresponding days of the motor car, when the latter was undeveloped and as expensive a proposition as the airplane is to-day.

While we have built planes in quantity, we have not designed in quantities. At the time of the war we had to take what we had and develop it. We had no knowledge of other than amateurish materials. But with the war we have developed materials, constructions and the production end of aircraft. Good engines have been developed, possibly not the right size, but good enough for this stage of development. Now we are coming to the point where we must have greater safety than with the war machines, a place to land on small fields and at slower speeds.

Mr. Stout told further of the wonderful achievements of the wireless telephone as regards aviation, particularly in policing aerial routes and keeping the pilot informed of his location and weather conditions ahead. The speaker in taking up the subjects of parasite resistance and lift-drift ratios supplemented his talk with blackboard illustrations. He said the lift-drift ratio of the best machine is about 8.4; that is, 8.4 lb. can be carried for every pound of propeller pull. This means a limitation of loads to be carried, and fuel in proportion to horsepower. If a machine can be developed with a low enough parasite resistance, so that the lift-drift ratio is about 10 or more, then if we are lucky and have a calm day we might be able to fly from Halifax to Ireland. As yet we have not produced any such machine.

The use of steam in handling kerosene as engine fuel was the chief topic of the paper on Developments in Burning Kerosene as Motor Fuel, presented by Otto E. Szekely, chief engineer and production manager of the Velie Motors Co., Moline, Ill. The author dwelt particularly on the experiments and research work done by this concern in using kerosene with its tractor engine. Increased volumetric efficiency, Mr. Szekely said, has been obtained by means of a fairly successful method consisting in vaporizing the kerosene and drying the mixture in connection with the superheated steam and fuel washing. This paper will be discussed at the next meeting.

Following are the new officers of the Midwest Section elected at this meeting: Chairman, Dent Parrett of the Parrett Tractor Co.; treasurer, Francis W. Parker, Jr., of the firm of Parker & Carter, patent attorneys, and secretary, C. S. Rieman of the Elgin Motor Car Co.

Industrial Board Disbanded

WASHINGTON, May 12—All attempts to fix prices of basic commodities by the government were ended when the Industrial Board, which is headed by George Peek, disbanded this last week following the refusal of the Railroad Administration to accept the steel prices as set by the Industrial Board. It is also stated that one reason for the termination of the Board was that the Attorney General found all such price fixing illegal. All of the industries which submitted figures to the Board and agreed upon prices, including steel, sand, gravel, crushed stone, glass and lumber industries, were released from the fixed and proposed prices with the termination of the Board.

Uniontown Entries Complete

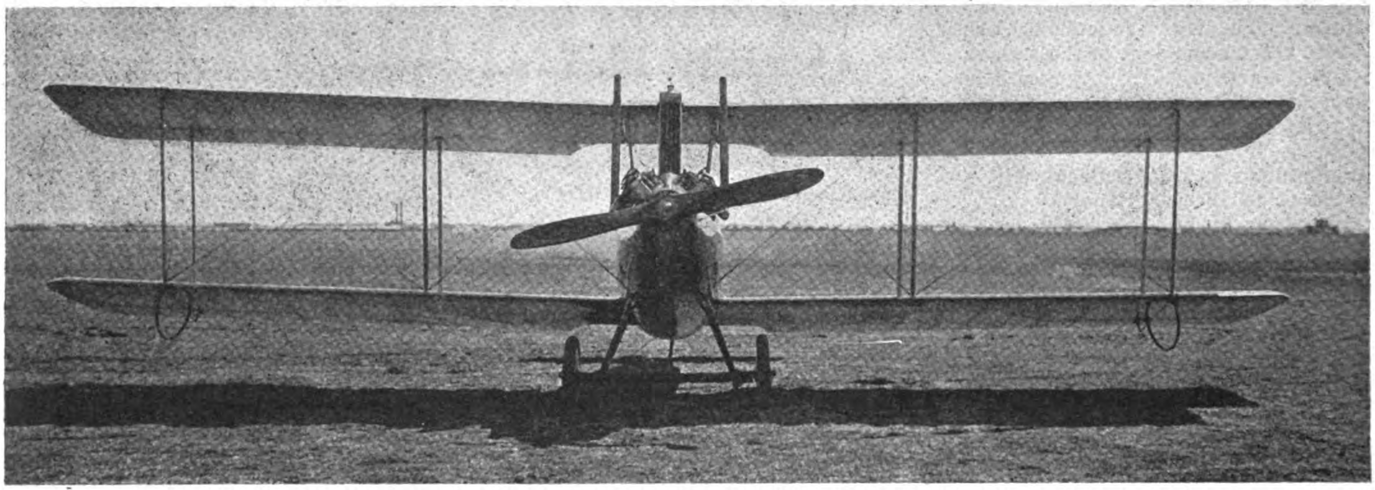
NEW YORK, May 12—The opening racing event for the year on American speedways will be the 112-mile race on the Uniontown speedway on Saturday. A good many of the racers will go from there to Indianapolis to take part in the 500-mile race on May 31. Gaston Chevrolet is entered for both Uniontown and Indianapolis if he is reinstated by the American Automobile Association by that time. If not some other driver will have to be chosen for his Frontenac special. The 16 following names are entered for the race at Uniontown:

Driver	Car
Louis LeCocq	Roamer special
Kurt Hitke	Roamer special
Eddie Pullen	Hudson special
Cliff Durant	Chevrolet special
Harold Simmons	Hudson special
Wilbur D'Alene	Duesenberg special
Denny Hickey	Stickel special
Ray Howard	Peugeot special
P. W. Monahan	Johnson special
Joseph Boyer	Frontenac special
Louis Crevrolet	Frontenac special
Gaston Chevrolet	Frontenac special
Ralph Mulford	Frontenac special
Tommy Milton	Duesenberg special
Fred McCarthy	Hudson special
Eddie Hearne	Durant special

Washington-New York Air Mail Service Completes Year

WASHINGTON, May 12—The Air Mail Service between Washington and New York has completed its first year, during which time it represents 128,037 miles of air travel and 7,720,840 letters carried. The revenue from airplane mail stamps totaled $159,700 and the cost of the service, $137,900.06.

The record of the entire service for the year shows 92 per cent of performance. Out of 1261 possible trips, 1206 were un-



Front view of the Curtiss Oriole, which carries two passengers in addition to the pilot

dertaken and 55 were defaulted on account of weather conditions. During rain, fog, snow and electrical storms, 435 trips were successfully made. The year's travel of 128,037 miles represents the total out of a possible 138,092 miles. Fifty-one forced landings resulted on account of weather and 37 on account of engine trouble.

One of the lessons learned from the operation of the service is that the element of danger existing in military and exhibition flying is almost entirely absent from commercial flying. The year's operation including flights at altitudes as low as 50 ft. during periods of invisibility. During the year no airplane carrying mail has fallen, and no aviators have lost their lives.

The year's flying has established the fact that 200 ft. of visibility from the ground is the limit of practical flying, although a number of flights were made at lower altitudes. This was discovered by means of a device built by the Bureau of Standards in the form of a radio directional compass. The objection to flying above the ground fog, rain, snow or heavy clouds with single engine planes lies in the possibility of the engine's stopping over a village or other bad landing place with a limited radius of visibility. Flights were made in gales from 40 to 60 miles an hour.

The same 6 planes that were in operation at the inauguration of the service are in operation to-day, and the two planes that made the initial flights on May 15, 1918, will make the initial flights on May 15, this year, to mark their first anniversary.

Salisbury to Make Axles Only

JAMESTOWN, N. Y., May 14—The Salisbury Wheel & Axle Co. has changed its name to the Salisbury Axle Co., Inc., and has discontinued the manufacture of wheels for cars

Blakely in New Factory

DETROIT, May 12—The Blakely Mfg. Co. has moved into its new factory at the corner of Wabash and Stanley Avenues.

The Oriole—New Curtiss Commercial Plane

BUFFALO, May 12—The Curtiss Aeroplane & Motor Corp. has put out its first purely commercial airplane—the 3-passenger Oriole, which was designed by W. L. Gilmore, airplane engineer for the company. The plane embodies a new idea in body construction, special ply wood being used. Longitudinal stringers, running fore and aft, add to the rigidity. The body is made in two parts and connected on the center line. It is elliptical in section and contains no real diaphragms.

The passengers' comfort has been well looked after in the design. There are no controls in the front cockpit, which seats two passengers abreast. The upholstering is of leather and a curved windshield protects the occupants and gives them a clear vision while flying.

The machine is equipped with a self-starter. It is colored to represent the oriole, the body being orange and the wings yellow and black. The engine is a Curtiss OX-5, which was used in the JN-4D training planes. The machine is 25 ft. long, 36 ft. from tip to tip and is 9 ft. 5 in. high. Its total weight, loaded, is 2188 lb. and it carries a useful load of 767 lb. It has a maximum flying speed of 85 miles per hour.

On its initial flight, the Oriole captured two prizes offered by the Pan-American Aeronautical Congress for the first airplane to fly to and from Atlantic City on the opening day. The machine was piloted by Roland Rohlfs, Curtiss test pilot, who, on the return trip, made the distance of 109 miles in 1 hr. 11 min. On the way to Atlantic City, the Oriole carried as a passenger Victor Hugo Barrance, Cuban consul-general.

Proposed Air Service Between Australian Capitals

WASHINGTON, May 12—A company has been organized, according to reports, called Aircraft, Ltd., to establish interstate air service in Australia, to begin within the next year. It is expected that aerial service will be operated between the capitals of all of the states of the Australian continent. Planes will be used to carry 20 passengers each. They will be used for both passenger and express service.

Flying Fatalities Increase

WASHINGTON, May 9—Flying fatalities at United States flying fields have increased since the armistice was signed. From June 1, 1918, to the armistice the average hours flown per fatality were 3149, while from the armistice to date the average is 1852 hours, an increase of 41 per cent.

The following table shows the pre-armistice rate compared with the monthly rate since the armistice:

Period	Fatalities	Hours flown	Hours flown per fatality
June 1 to Nov. 11, 1918..	156	491,283	3,149
Nov. 11 to Jan., 1919...	42	78,831	1,877
January	6	16,498	2,750
February	17	15,688	922
March	14	28 072	2,005
April	6	14,650	2,441

American Cars May Not Be Exhibited at Olympia

LONDON, ENGLAND, May 1—No decision has been made as yet as to whether importers of American cars will be permitted to exhibit at the coming Olympia show in November. Importers are not at all satisfied with the present ruling restricting automobile importations, and it would be a serious blow to them if they were not permitted to exhibit their cars at the Olympia show on a par with other makers.

Industrial Clinic for Labor

WASHINGTON, May 10—Plans for the establishment of industrial clinics by organized workers in their respective localities to be under government supervision have been laid before the 800 central labor bodies in this country by the Department of Labor. Under the plan expert medical examination, advice and treatment under government supervision will be available to the workers upon payment of fees ranging from 10 cents to $1. Supervision of the clinics by the government will be undertaken by Dr. A. J. Lanza, Chief of the Division of

Industrial Hygiene and Medicine, Department of Labor.

If these plans are adopted by organized labor, the immediate effect will be to abolish the existing industrial health systems which are being operated by many of the large manufacturers at the expense of the various corporations. Some corporations have followed a plan of this kind for several years, examining workers upon their application for employment, including dental, eye and ear examinations, and maintaining a corps of doctors and nurses to look after the health of the employees and visit those who are ill. There has been some objection to this plan voiced by organized labor on the ground that there is likely to be discrimination against union workers. The new plan, it is thought, will be more favorably regarded because it eliminates this possibility.

Citroen Workers on Strike

PARIS, April 23—All the men in the Citroen automobile factory came out on strike this week. The men asked for the abolition of night work and overtime, the immediate adoption of the 8-hour day without a reduction in wages, and an increase of 5 cents an hour on all salaries. The Citroen company decided on a lockout, and this was followed by a general strike of the 6000 workpeople employed by the firm. It is maintained by the workers that wages are lower in the Citroen factory than in other similar establishments.

Italian Factories Closed Through Labor Disputes

PARIS, April 23—Information is received from Turin, Italy, to the effect that practically all the automobile factories are closed owing to labor troubles. The disputes affect Fiat, Lancia, Scat, Isotta-Fraschini and others.

AC Speedometers in Production

FLINT, MICH., May 10—Manufacture of AC speedometers has been started by the Champion Ignition Co., maker of AC spark plugs. At the time of the armistice 40,000 AC aviation spark plugs were turned out daily for the government.

The plant built for government work will be used for the production of spark plugs and speedometers. Jo Berge will be in charge of the speedometer development and manufacturing departments.

Dodge Bros. Open Export Office in New York

NEW YORK, May 9—Dodge Brothers, Detroit, have opened an export office here at 43 Exchange Place. John C. Mathews, who for a number of years has represented the Dodge foreign sales department in this city, will be in charge of the new office.

Dividends Declared

Studebaker Corp. of America, South Bend; quarterly dividend, 1 per cent common, 1¾ per cent preferred, payable June 1 to stockholders of record May 20.

Michigan Housing Situation Critical

LANSING, May 10—The housing situation here is becoming critical. With all of the city's industries reaching capacity production and many planning to greatly increase their output, Lansing faces a shortage of labor as well as homes to house the workers. The General Motors Corp. expansion plan calls for the erection of hundreds of houses for Oldsmobile workers and other G. M. C. concerns. Inasmuch as the industrial boom is general, the new G. M. C. homes will not begin to care for the existing shortage and the influx of new families. The Chamber of Commerce and many individual companies are working on plans to solve the housing problem.

MUSKEGON, MICH., May 10—Muskegon will build between 750 and 1000 new homes this summer, which number is sufficient to relieve the present shortage of homes, which is not serious here. The Muskegon Building & Loan Association, by the formation of a mortgage loan company with a liberal loaning policy has increased its capital and activities. Local manufacturers are not building homes for their workingmen. This plan was tried some years ago but the workingman did not readily respond to the idea of buying his home from his employer.

PONTIAC, MICH., May 10—The Beudette Body Co. is backing two hotel projects for housing its workingmen. The company has also provided temporary working quarters for a limited number of men in one of its buildings.

The General Motors Truck Co. has leased the Wellington Hotel and will provide rooms there for 100 men. The Oakland Motor Co. is rushing work on an apartment for men, and the Wilson foundry rooming house is nearing completion. Several hundred single men will be accommodated in these buildings. The result is expected to bring about a sharp decline in rental of houses and rooms in Pontiac.

GRAND RAPIDS, MICH., May 10—The housing situation in Grand Rapids is quite satisfactory. There is only a slight shortage of homes at the present time. This city ranks second in the United States as to the percentage of home ownership, being surpassed only by Spokane, Wash. Five building and loan associations have over 4,000 borrowing members.

A number of contractors are building homes for 10 per cent down and 1 per cent a month. It is estimated that 500 new homes would adequately relieve the situation, but the possibilities are that before fall the city will need more than this.

Canadian Maxwell and Chalmers Orders Ahead of Production

WINDSOR, ONT., May 9—The Canadian plants of Maxwell and Chalmers are far behind in filling orders. February shipments were only 65 per cent of February orders. The March record is about the same in spite of the fact that the plant is working on its midsummer schedule. Production is difficult, it was explained, because material continues to be as hard to get as it was a year ago.

Detroit Seamless Tube Plant Started

DETROIT, May 12—The Detroit Seamless Steel Tubes Co. has begun construction of a $3,000,000 plant on a 60 acre tract on Warren Avenue. The first section, costing $1,000,000, will be completed by Jan. 1. The company's present location has been sold to the Pennsylvania Railroad.

The structure will be steel and glass with brick and concrete facing. The roof will be of tile. The plant proper will occupy a space of 350 x 550 ft. It will consist of three buildings for manufacturing, a separate heating plant and a 2-story administration building. The three manufacturing units will each be 90 x 550 and 45 ft. high.

About 150 homes for workmen of the company will be built in the vicinity of the plant. The total capacity of the first unit will be 2,500 tons of seamless steel tubing a month, the range of sizes being from ½ in. to 6 in. in diameter.

Cletrac New Name for Cleveland Tractor

CLEVELAND, May 9—The Cleveland Tractor Co. has adopted the name Cletrac as the registered name of its tractor. Tank-type-tractor is used in connection with the name, as it is of crawler construction.

Acason Truck Sales to Be Handled from Factory

DETROIT, May 9—Sales and service of the Acason motor trucks will be handled direct by the factory, according to an announcement by Vice-President and Director of Sales Harry Conlon of the Acason Motor Truck Co. The sale of Acason trucks at retail in Detroit and wholesale for Michigan will be handled by a special department of the factory, which will be in charge of H. P. Mills. Arthur C. Acason will assist Mr. Mills.

L. V. Estes Moves

CHICAGO, May 9—L. V. Estes, Inc., industrial engineer and accountant, has moved its offices from the McCormick Building to the fifteenth floor of the Century Building, 202 S. State Street.

U. S. Light & Heating Building

NIAGARA FALLS, N. Y., May 9—The U. S. Light & Heat Corp. is adding several new brick and concrete buildings to its present plant, which consists of 22 units, to give the company increased manufacturing facilities. Work is already under way. Several acres of adjoining property have been acquired for further expansion.

Ford's Mammoth War Work

DETROIT, May 12—Government war contracts held by the Ford Motor Co. exceeded $560,000,000 and represented work for the Army, Navy and Air Service. The following items will give some idea of the work done by the Ford interests during the war:

More than 2,000,000 steel helmets.

Order for 5000 12-cylinder Liberty engines. Over 1500 had been delivered when the armistice was signed, and the company was just striking production capacity.

10,000 caissons, mainly for 155 mm. guns. Something over 8000 delivered.

Order for 112 "Eagle" boats, 200 ft. long, 25 ft. beam. Something like 25 delivered when the order was reduced to 62. The balance will be finished by Aug. 1.

More than 8000 trucks.

More than 25,000 regular Ford cars.

More than 6000 ambulances.

400,000 cylinders for Liberty engines. The government placed the order with the Ford Motor Co. to make all the cylinders for all the Liberty engines made in America. The original order was practically completed when the armistice was signed, and a new order for $300 000 had just been entered.

700,000 bearings for the Liberty engine. The government placed the order with the Ford company for all the bearings for all the Liberty engines made in the United States. On this order over 400,000 bearings had been delivered.

700,000 cylinder forgings for Liberty engines. The government placed orders with the company for all the cylinder forgings for all the Liberty engines made in America. Over 400,000 had been delivered.

A large volume of experimental work was done in building 3-ton military tanks, and the government had just placed order for 15,000 of the small, two-man, military tanks, and 3000 of the 6-ton military tanks. Cancellation came before more than a dozen or so had been delivered. But the foundations had been laid and the superstructure almost completed for an enormous building in which tanks alone were intended to be built.

Motion picture reels in behalf of Liberty loans, Red Cross and Patriotic fund work were made by the company and supplied to the government in sufficient quantities to serve the entire United States in motion pictures. Motion picture reels in volume sufficient to serve the armies of the States in France, Italy and Palestine were furnished by the Motion Picture Department of the Ford Motor Co.

The company also did more than $1,000,000 of work in the production of special devices in the naval department of the British government.

It also furnished the government with 275 skilled mechanics for work in France.

The Ford company, through its chemical laboratory, co-operated with the manufacturers of gas masks for the United States army.

An average of 34,000 men and women were employed by the main factory at Highland Park; 8800 men at the shipbuilding plant on the River Rouge, 4000 men employed at the new blast furnace, in course of construction on the River Rouge, 250 men employed at the carbureter plant, or an average of 45,000 employees, practically all on 100 per cent government work, under a standard 8 hr. day and a minimum wage of $5 a day.

New Tractor Company

EVANSVILLE, IND., May 12—A new company, capitalized at $1,000,000, has been formed for the manufacture of farm tractors. Robert C. C. and J. B. Graham, of Graham Bros., Inc., glass manufacturers, and Benjamin Bosse, president of the Bosse-World Furniture Co., are interested in the new concern. Besides a local plant it is planned to have a branch at Loogootee.

Eugene McGuckin in New Offices

PHILADELPHIA, May 10—The Eugene McGuckin Co. has moved its offices from 105 North 13th Street to 1211 Chestnut Street.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Climber Cars in Production

LITTLE ROCK, ARK., May 12—The Climber Motor Corp. has just completed its new plant here. Machinery is being installed and operations will start immediately. It is a 1-story building of concrete, steel and glass, 100 x 300 ft. Other units will be built later. The Climber Co. will manufacture a passenger car, truck and tractor. The truck and tractor departments will not be established until passenger car production is well under way.

George Schoeneck is chief engineer. He has been in charge of a small shop in Detroit where the first Climber experimental cars were made. H. F. Buhler is sales manager of the company. The plant will start work with a force of 100 men. It is proposed to produce 10 cars daily during the first year.

New Vim Tractor Co.

SCHLEISINGERVILLE, WIS., May 10—The Vim Tractor Co. has been organized to take over the plant and equipment of the Standard Machinery Co., manufacturer of gas and kerosene engines, which recently has developed a tractor design to be placed in quantity production by the new corporation. The Standard works are being re-tooled and will be ready to begin manufacturing tractors at once. Officers of the Vim company are: President, Charles D. Storck; vice-president, John F. Mayer; secretary, Dr. Philip M. Kauth; treasurer, Peter Schuck; works manager, Otto E. Zahn.

Samson Tractor Buildings Under Way

JANESVILLE, WIS., May 10—Contracts were awarded Thursday by the Samson Tractor Co., subsidiary of General Motors Corp., for the construction of the second unit of the new tractor plant here, where a total investment of $4,500,000 is contemplated. The first unit, 200 x 500 ft., was finished late in March. The second building will be an exact duplicate of the original unit. When it is completed, the assembling of Samson tractors will be done by the "endless chain" method. A third unit will probably be erected in August or September.

Oldberg Adds to Manufacturing Facilities

DETROIT, May 8—The Oldberg Mfg. Co., makers of automobile and marine mufflers, will greatly increase its manufacturing facilities through the purchase of a 3-story brick factory building on East Grand Boulevard, formerly occupied by the O'Neill Mfg. Co.

Boring Tractors on Market Soon

ROCKFORD, ILL., May 10—The Boring tractor is getting into production and will be on the market by June 1. The Boring Tractor Corp. has built a new fireproof factory at Blackhawk Park Avenue and Kishwaukee Street, which will be occupied during the present week. It is a stone building, 70 x 200 ft., monitor construction, and will have a capacity of about 300 tractors a year.

The Boring tractor is a 2-wheel tractor of 2-plow capacity. It has a new and simple power lift for the plows and enclosed chain drive.

K-W Wins Switch Litigation

NEW YORK, May 13—The K-W Ignition Co., Cleveland, has won its suit against the Goodrich-Lenhart Co. for infringement of certain patents on ignition locks. The United States District Court for the Eastern District of Pennsylvania has held that patents Nos. 841,844 (Burnet), 1,015,300 (Cox) and 1,253,470 (Cox), under which the K-W Ignition lock switches are made are valid and infringed by lock switches made by the Goodrich-Lenhart Co. The latter company has paid certain damages to the K-W company and is allowed to dispose of a comparatively small quantity of lock switches which it now has on hand.

National Engineering Company Enlarging Force

SAGINAW, May 12—The National Engineering Co., acquired some time ago by the General Motors Corp., is employing about 200 men, but it is said the force will be doubled in a short time. The company makes the engine crankshaft for the Oakland Motor Car Co.

Allith-Prouty Adds Hubs to Line

DANVILLE, ILL., May 13—The Allith-Prouty Co., engaged in the manufacture of steel and iron products, has installed new machinery and will turn out hubs and other parts for motor vehicles. Thirty additional machinists will be required to take care of the new line. The new machinery will have a capacity of 50,000 automobile hubs per month to start. The war contracts have all been filled and the plant will hereafter handle the regular line of business.

Perfex Creditors Meet

RACINE, WIS., May 14—At the first meeting of creditors of the Perfex Radiator Co., Julius J. Goetz of Milwaukee, previously appointed receiver, was elected trustee under bond of $50,000. A court order was filed authorizing the trustee to continue and operate the business for 30 days. The Perfex plant has been in operation since bankruptcy proceedings were filed March 28. It is believed that creditors will succeed in effecting a reorganization and that they will realize practically 100 per cent on their claims. The next meeting of creditors will be held Monday, June 2, in the federal court at Milwaukee.

Flanders Retiring from Management of Maxwell

DETROIT, May 12—Walter E. Flanders, chairman of the board of directors of the Maxwell Motor Co., Inc., has advised the Maxwell company that he will not again contract with them July 31, but will retire from the management of their affairs. He will probably retain an interest in the Maxwell company, but will cease active work. Mr. Flanders will not state just what his future plans are. It is understood, however, that shortly after finishing his duties at the Maxwell plant he will board his new yacht for a long cruise down the Atlantic coast through the Panama Canal for California.

Mr. Flanders, it is said, has disposed of a large part of his property holdings in Michigan and Ohio. It has been said that he contemplates locating in California, where he will establish a factory to make a new automobile. That he will go into the automobile manufacturing business in California, Mr. Flanders denies.

E. W. Templin, formerly assistant engineer of the Selden Motor Truck Co., and more recently production manager of the Bessemer Motor Truck Co., has joined the staff of the Goodyear Tire & Rubber Co. as motor truck engineer attached to the development department.

Raymond F. Brown has been appointed purchasing agent of the Bantam Ball Bearing Co., Bantam, Conn., to succeed C. D. Stoddard, who resigned.

Ernest P. Johnson, who has been with the Frankl'n Automobile Co. since 1915, succeeds Walter C. Biddle as assistant sales manager. Mr. Biddle resigned to handle Franklin distribution in Toledo.

Sherman W. Dorman who for the past three years has handled the buying of accessories for the Biddle Purchasing Co. for domestic and foreign trade, is now connected with the Overseas Motor Service Corp. as manager. The corp. will handle a number of accessories in foreign fields exclusively, those controlled by the United Motors Co. being prominent.

Lynn V. Blankman has been appointed manager of the central west territory for the United Aircraft Engineering Corp., New York. His headquarters are at 514 Westminster Building, Monroe and Dearborn streets, Chicago.

Connecticut Telephone & Electric Adds to Engineering Staff

MERIDEN, CONN., May 9—F. J. Croton, Jr., and John A. Terrell, both recently released from government service, have been added to the engineering staff of the Connecticut Telephone & Electric Co., Croton as mechanical engineer and Terrell as assistant to the chief radio research engineer. Mr. Croton, before enlisting in the Chemical Warfare branch of the army, was in charge of a die house of the J. A. Barbour Co.

Men of the Industry

Changes in Personnel and Position

Squires Engineering Co. Formed

DETROIT, May 9—John Squires, formerly chief engineer of the Signal Motor Truck Co., has organized the Squires Engineering Co. and has opened a laboratory here. Mr. Squires is working on a steam power plant for distillate fuel. He hopes to have it in operation in an experimental car by early fall.

Fred I. Tone, former vice-president and chief engineer of the American Motors Co., Indianapolis, and later chief engineer of the United States Ball Bearing Co., is now with C. Harold Wills, former chief of the Ford Motor Co., who is making ready to enter the car manufacturing field in Detroit.

P. C. Gunion is now assistant manager of the new Industrial Division of the General Motors Corp.

Peter T. Hill has joined the sales department of the Torbensen Axle Co.

Guy Wright, formerly assistant sales manager of the Buda Motor Co., Harvey, Ill., has been made sales manager, succeeding Lon Smith, who resigned to become sales manager of the Midwest Engineering Co., Indianapolis.

H. A. Flogaus has been appointed to the engineering staff of the Maibohm Motors Co., Sandusky, Ohio. Previously he was with the Willys-Overland Co., Toledo, and later with the Curtiss Aeroplane & Motor Corp., Buffalo. Last year he was stationed at Washington as assistant chief draftsman of the Motor Transport Corps, in charge of the chassis design of Class B trucks. Since leaving government service he has been chief tool engineer with the Matthews Engineering Co., Sandusky.

Trailer Manufacturers Assn. Office

NEW YORK, May 12—The Trailer Manufacturers Association of America, recently organized to deal with questions of importance to the trailer industry, has opened offices at 110 West 40th Street. Legislation affecting trucks and trailers is one of the most important matters that will be handled by the association. The question of exemption of trailers from taxation under the Revenue Act of 1918 has also been taken up. A publicity campaign to familiarize the public with the advantages of haulage with the use of trailers and the development of transportation by highway will be part of the association program.

White Resigns as Cadillac Vice-President

DETROIT, May 12—D. McCall White, vice-president and assistant general manager of the Cadillac Motor Car Co., whose resignation is to take effect at once, will not discuss his future plans further than to say that he will remain in the automotive business and that his operations will be very extensive.

Mr. White upon coming to America, from England, became a member of the engineering department of the Cadillac company, later being appointed chief engineer. He started with that company in a secret office in the heart of Detroit in March, 1914, and commenced the design of the 8-cylinder Cadillac engine, which he completed in less than 2 months. He then went East, changed his name, calling himself David Wilson, and had the parts for 3 cars completely machined all ready for assembly, returning to Detroit on June 4, exactly 117 days after the first pencil lines were drawn on the designing board. The car proved successful on test and the tooling up was immediately commenced, with the result that the Cadillac Motor Car Co. announced to the public on September 25, 1914, that it would build an 8-cylinder car, delivering the first 40 cars by the middle of October. After getting into full production, the company completed 13,000 by the middle of June, 1915.

Shortly after the United States entered the war, Mr. White was appointed a member of the committee which was charged with the placing of the Liberty engine on a production basis.

Walter T. Roose, formerly in the purchasing department of the Studebaker Corp., has become sales representative for the Motor Materials Co., Detroit.

Russell Munro has returned from France and has resumed his duties as assistant advertising manager of the Ford Motor Co., Detroit.

James G. Roe has resigned as advertising manager of the J. C. Wilson Truck Co., Detroit, and has joined the Green-Fulton-Cunningham Co., advertising agents.

A. E. Crysler has joined the Commerce Motor Car Co., Detroit, as assistant to the director of sales and advertising, G. D. Wilcox.

New Directors for Allis-Chalmers

WILMINGTON, DEL., May 10—The Allis-Chalmers Co. at its annual stockholders' meeting elected the following directors for the ensuing year: J. H. McClement, chairman; Otto H. Folk, Oliver C. Fuller, J. D. Mortimer, Fred Vogel, Jr., Charles F. Pfister, Knox Pim, F. O. Wetmore, Arthur W. Butler, Arthur Coppell, Charles W. Cox, Oscar L. Cubelman, I. C. Hutchins, Jr., William T. Abbott, James P. Winchester, Dr. C. E. Albright and Charles Hayden.

Counteracting the Propaganda of the Irreconcilables

(*Continued from page* 1072)

undertaken within the factory for the benefit of the worker, they have been confined, almost without exception, to training in the conditions of work and not in the necessities of business as such or in any other way that would broaden their outlook upon the character of industrial organization. Under such circumstances the propaganda from which we quoted in the beginning of this article is particularly plausible and not without its allurement to the worker who gets his information about capital from the more sensational newspapers and from the similarly informed workers with whom he spends his social hours.

Under such circumstances the most carefully developed plans for co-operation with the workers, the most efficient means for allowing them a voice in the government of their working conditions and the keenest suggestions and development for their comfort and safety are of little value unless they are promoted with such care and developed with such patience that the discouragements which must be faced are none of them sufficient to alter the determined policy.

It is obvious that the workers have learned the strike method of enforcing demands very thoroughly; so thoroughly that they are apt to give it an importance and a power which it does not possess in fact; that they are suspicious of everything which is proposed by the manufacturer; that they have learned to regard capital and the present capitalist system, so called, as a direct bar to their enjoyment of greater benefits, and that the only means of education which ordinarily come into their life are newspapers with their inevitable inaccuracy and partisanship and who are generally emphasizing and confirming this opinion. In addition to all this they are subject to the ceaseless propaganda of the radical elements in the labor bodies who are committed to the destruction of the present system and who are constantly pushing their point of view, not without intelligence and not without a keen political understanding of the people upon whom they are working.

All these things must be taken into account by the manufacturer, and particularly should they be studied with an eye to their importance in their relations to the educational processes, to the character and understanding of the supervisors and to the promotion which must be undertaken if any understanding of industrial organization and its necessities is to permeate the minds of the workers in any reasonable time.

The matter is proving to be a sufficiently difficult one in Great Britain, where the foreign element is small and all the people have grown up with the same political traditions and the same racial background. It is much more complicated in this country, where it is not unusual to have from six to twenty separate races among the workers in a single manufacturing plant; with political histories ranging from feudal autocracy to trivial communism, with little or no knowledge of the political and racial conceptions which govern this country and with less understanding of the significance of their surroundings.

It is inevitable that plans which appear to the manufacturer to be of great benefit to the workers should be accepted by the workers without enthusiasm or rejected by them or should fail to bring industrial peace within the organization because of the inherent difficulty in securing a common idea and developing a common purpose where the ideas are already so far apart. Nevertheless the old Scotchman's statement is still correct, that it is up to the manufacturer to find out what his workmen think and to understand them a great deal better than they can be expected to understand him.

Chicago-Cleveland Air Mail

WASHINGTON, May 13—The air mail service will inaugurate a route between Chicago and Cleveland beginning May 15. The service will advance delivery of letters at Cleveland and Boston by 16 hours, and at Albany, New York City and Springfield, Mass., by 6 hours.

Mail from San Francisco and the entire Pacific Coast states put on Burlington train No. 8; mail from South Dakota and Northern Illinois put on Illinois Central No. 12; mail from Northern Minnesota and Northern Wisconsin put on Northwestern train No. 514; mail from Minnesota, North Dakota and Montana put on C. M. & St. P. train No. 18, and mail from Kansas City and the entire Southwest put on Santa Fe train No. 10 will reach Chicago in time to make connection with the air mail east bound. The mail from these trains will be taken direct to the air mail field. At Cleveland the air mail will catch the New York Central train at 4 p. m. for the East.

Under this arrangement the air mail will be delivered in Cleveland and Boston on afternoon deliveries instead of the following morning. At Albany, New York City and Springfield, Mass., this mail will catch the morning delivery.

Letters mailed in New York City in time for New York Central train No. 19, leaving at 5.31 p. m., will reach Chicago in time for 3 o'clock afternoon delivery by carrier instead of the following morning carrier delivery as would be the case if sent by train.

Airplane stamps or ordinary postage at the rate of 6 cents per ounce must be used on mail, and the letters conspicuously marked "AIR MAIL." A special delivery stamp in addition to the air mail postage will insure still greater expedition of letters at points of delivery.

Haynes Enlarging Plant

KOKOMO, IND., May 14—A $450,000 addition to the Haynes automobile plant to be built here will include an assembling plant and forge shops, and will be the beginning of $1,500,000 worth of construction which the Haynes company will put up.

Curtiss K-6 and K-12 Aircraft Engine

(*Continued from page* 1054)

oil temperature regulator. This consists of a coil, having a cored water passage and two cored oil passages. Water of the cooling system circulates through this temperature regulator while on its way from the radiator to the pump. This temperature regulator is not merely an oil cooler, but also serves to heat up the lubricating oil quickly when first starting the engine from cold. In first starting an engine, the jackets heat up much quicker than the lubricating oil, as the latter circulates only very slowly. By passing the cooling water through the duct of the oil temperature regulator, the oil can be brought up to normal working temperature much quicker than would otherwise be possible.

In regular operation, the oil tends to assume a much higher temperature than that of the cooling water, and then the temperature regulator acts as an oil cooler. It keeps the temperature of the oil down and maintains its lubricating properties. After passing through the ducts in the regulator, the oil passes through the triple return pump and then to the oil chamber, whence it is recirculated. There is an oil gage on the oil pan, which is calibrated to show the amount of oil in the sump in gallons. There is an oil filler on the top of the crankcase. The oil pressure relief valve is adjustable, so that the pressure under which oil is fed to the bearings can be varied to suit condition of work.

Cooling water is circulated by a centrifugal pump mounted on a vertical shaft at the forward end of the engine. The pump used on the K-12 is of the double type, having two outlets on opposite sides, one connecting to each cylinder block. The water, as it comes from the radiator, passes first through the oil temperature regulator, and then enters the pump through the pump cover casting. From the pump the water is delivered into the cylinder jackets at the lowest part of it. From the cylinder jackets the water passes into the head jacket through a series of drilled holes. There the water circulates around the valve passages and then leaves the head casting at a point between the valves on each cylinder. Next it passes through the inlet manifold jacket, and thence it returns to the radiator.

The reduction gears, which are of the herringbone type, with 5-7 pitch, give a reduction in the ratio of 5 to 3. The gears are bolted to flanges with alloy steel bolts. Each half of the herringbone gears has a width of face of 1 in. The gears are first roughed out and then heat-treated, after which the centers and faces are ground, and the gears are then recut.

Sewell Cushion Wheel Dividend

Sewell Cushion Wheel Co., Detroit, 7 per cent dividend declared on preferred and common, for stockholders of record June 1. Within 60 days factory branches will be opened in Portland, Ore., Los Angeles and San Francisco.

*Aug. 22-23—Elgin, Ill. Road race.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Sept. 27—Allentown, Pa. Dirt track event.

*Oct. 1—Cincinnati, O. Speedway race.

†Sanctioned.
*Tentative dates.

*Oct. 4—Trenton, N. J. Dirt track event.

*Oct. 11—Danbury, Conn. Dirt track event.

CONVENTIONS

May 1-June 1—Atlantic City, N. J. — Pan-American Aeronautic Convention and Exhibition—Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation.

May 21-24—Washington — Conference on Weights and Measures—Bureau of Standards.

June 2—Chicago, Ill.—Natl. Gas Engine Assn. Hotel Sherman.

June 3-6 — Washington, Pan-American Commercial Conference, Pan-American Building.

June 23-28—Ottawa Beach, Mich.—S. A. E. Mid-summer Meeting.

Sept. 22-24 — Philadelphia. Annual Convention National Association of Purchasing Agents, Bellevue-Stratford.

Swiss Market for Motor Cars

WASHINGTON, May 11—Consul Lewis W. Haskell reports that Switzerland will have to look to the United States for motor cars and trucks, lubricants and gasoline. Previous to the war $125,000,000 worth of goods annually were bought from Germany, and American manufacturers will undoubtedly have a future market in Switzerland if terms, prices, etc., are made attractive to the Swiss buyer.

Tractors in British Guiana

WASHINGTON, May 12—There are 50 tractors in use in British Guiana, according to a consular report, chiefly in the rice and sugar industries. It is expected that the number will be increased within the next few years. The soft soil during the wet season makes the crawler type of tractor popular.

Cars in Venezuela

WASHINGTON, May 12—There are 300 automobiles in the Puerto Cabello district of Venezuela, chiefly 5-passenger cars of American manufacture, retailing at 52 to 100 per cent higher than in the United States, according to a consular report. The scarcity of skilled mechanics, high price of gasoline, poor roads and the cheap cost and care of pack animals restrict the sale of automobiles.

Market for Tractors in Guadeloupe

WASHINGTON, May 11—Despite the fact that practically all of the 75,000 acres devoted to sugar cane in Guadeloupe could be plowed and cultivated by tractors, there are at present not more than 7 tractors in use there, according to report of Consul Henry T. Wilcox. All of the tractors were brought from the United States. Satisfactory results are apparently obtained from both light and heavy tractors.

Grande Terre and Marie Galante, the islands on which most of the cane is grown, are almost level, and the portions now under cultivation are divided into about 1100 estates, which vary greatly in size. The soil is heavy and in many places marshy. The greatest drawback to the use of tractors in Guadeloupe is the lack of experienced operators. The ordinary laborers cannot drive such machines. Other obstacles are the numerous ditches which are found in the fields, the high cost of fuel, and the lack of initiative on the part of the planters.

The duties charged on tractors when imported from countries other than France are $1.31 per 100 lb. net, plus 3 per cent ad valorem. Such machines of French manufacture pay only the local duty of 3 per cent.

Truck Market in Scandinavia

WASHINGTON, May 12—There is a great demand throughout Scandinavia for American motor truck chasis, 3- to 5-ton, for immediate delivery, to cost about $3,000, according to the Department of Commerce, which recommends that American dealers make a personal canvass with demonstrations.

War Dept. Places Orders for Parts

WASHINGTON, May 12—Orders for motor vehicles and parts are still being placed by the War Department. The Locomobile Co., Bridgeport, Conn., received an order totaling $232,465.19 for spare parts for the Class B truck; Hendee Mfg. Co., Springfield, Mass., spare parts for motorcycles, $181,258.38; Harley-Davidson Motor Co., Milwaukee, spare parts for motorcycles, $132,301.25; Continental Motors Corp., spare parts for AA ambulances, $29,138.42.

Mexican Firm Issues Shipping Instructions

WASHINGTON, May 12—In order to facilitate imports into Mexico of automobiles from the United States, a concern in Mexico City has furnished complete shipping instructions to its American connections. Following are the complete directions:

1. *Packing.*—Pack goods securely for water transportation. Iron strapping is cheaper and more effective than heavy boxing.

2. *Marks and Numbers.*—Mark packages with brush or stencil, also with gross and legal weight on each. Show these marks and numbers on every document relating to the shipment. Number packages consecutively. Do not place any other marks or numbers whatever on the packages.

3. *Invoices and Packing Lists.*—Make five invoices and four packing lists. Send original and two copies of invoice and original and one copy of packing list to us. Send two copies of each to —— (name of forwarding agent in New York). Show contents of each package and itemized prices on each invoice. Show gross and legal weight of each package on packing lists; also the marks and numbers as they actually appear on the packages. If a package contains more than one class of goods give legal and net weights of each kind.

4. *Weights.*—Gross weight is the weight of the package and contents. Legal weight is the weight of the goods, together with the interior packing or containers, such as cardboard or tin boxes or bottles, but does not include the weight of the outside box.

5. *Cubic Measurements.*—Show on invoices and packing lists the measurement of each package.

6. *Local Truck Deliveries.*—New York shippers will send two copies of invoices and two copies of packing lists to —— (New York forwarding agents), who will give instructions for delivery to steamer.

7. *Inland Shipments.*—Shippers outside of New York will ship on local bill of lading to —— (New York forwarding agent), mark bills of lading "For export," and send same to —— (New York forwarding agent) with two copies of invoices and two copies of packing lists immediately shipment is made.

8. *Express shipments.*—When shipment is requested to be forwarded by express shippers will send express receipts to New York forwarding agents with two copies of invoices and two copies of packing lists immediately shipment is made.

9. *Insurance, Consular Invoice, and Ocean Bill of Lading.*—These will be attended to by our forwarders on receipt from you of the above-mentioned documents.

VOL. XL NEW YORK—THURSDAY, MAY 22, 1919—CHICAGO NO. 21

Transatlantic Flight Achieved

American Naval Airplane Reaches Azores; British Machine and Crew Are Lost

NC-4 Reaches Ponta Delgada, 1350 Miles from Trepassey Bay, After 17:02 Hours in Air—Hope Abandoned of Finding Hawker, the Sopwith Pilot, Who Left St. John's Sunday Night

THE Atlantic Ocean has been crossed in the air, and it was an American flying boat, manned by members of the United States Navy, that accomplished the historical feat. Lieut.-Commander Albert C. Read, piloting the Navy flying boat NC-4, reached Ponta Delgada at 1.50 p. m. (New York time) on May 19. After having completed the major part of the task of crossing the Atlantic, the plane is awaiting favorable wind to complete the journey to actual European soil, Lisbon being the selected landing place. From Trepassey Bay to Ponta Delgada the NC-4 was in the air 17:02 hours, traveling 1350 miles at an average speed of 79 miles an hour. The leg of the flight remaining is only 800 miles.

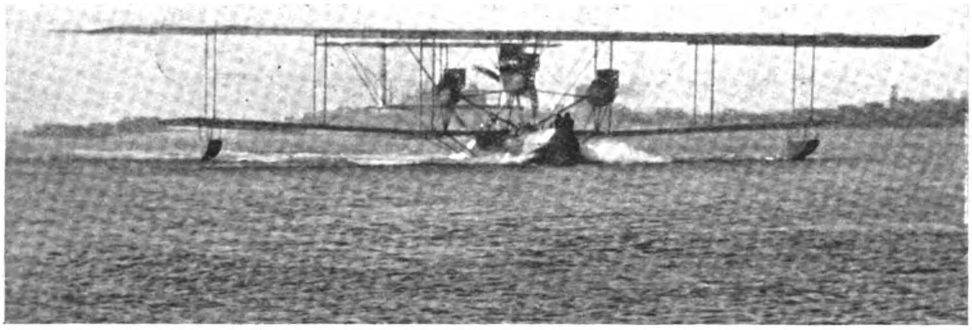
It was 100 years ago this month that the Savannah, an American built steamship, made the first trip across the Atlantic under man-made power.

Ever since Bleriot crossed the English Channel in an airplane in 1909 people interested in aircraft have looked forward to the date when the first transatlantic flight would be made in a heavier-than-air machine. It is an immense step from the twenty-odd miles of the cross-channel flight to the more than 2000-mile trip of NC-4 from Newfoundland to Portugal, and the difference in the two performances is a measure of the progress made in aircraft design and construction in the short span of ten years. The feat of Lieut.-Commander Read and his gallant crew will live in history both as a daring exploit crowned with success and as a milestone in the annals of mechanical flight.

Only one of the three NC boats which left Rockaway, N. Y., on May 8, succeeded in reaching the opposite side of the Atlantic. The NC-1, in charge of Lieut.-Commander Bellinger, was forced to alight on the ocean off the Azores in bad weather and was severely damaged. The crew were saved by a passing ship, but the plane was lost. Commander Towers' "flagship," the NC-3, got off its course when nearing the Azores, ran short of fuel, and had to alight on the ocean in foggy weather with heavy seas. It reached Ponta Delgada, Azores, under her own power, but was so seriously damaged by the buffeting she received that it was decided to disassemble her and ship her back to New York on one of the Navy vessels.

Lieut. Read's craft, the NC-4, which was pursued by ill luck during the first stage of the flight from Rockaway, N. Y., to Halifax, N. F., made the flight from Trepassey to Horta, Azores, without incident. She obtained a lead of about 30 minutes on the other planes and in consequence escaped the fog and heavy weather near the Azores that proved to be their undoing. On May 20 the NC-4 flew from Horta to Ponta Delgada, a distance of 150 miles, in 1 hr. 44 min., making its average speed for this distance 86 m.p.h. It was from Ponta Delgada that the last stage of the long air voyage was started.

The real start of the transatlantic flight was made



The NC-4 starting on her transatlantic flight. Leaving Trepassey, N. F., on the evening of May 16, the boat, after 17:02 hr. of continuous flight, reached Ponta Delgada May 19

Lieut.-Commander Albert C. Read, Commander and Navigator of the NC-4

from Trepassey, N. F., on the evening of May 16. The NC-4, which was belated in its arrival at Trepassey owing to a number of mishaps on the first leg of the long journey, had replaced one of her engines during the night. Mechanics worked on the machine all day. Her wings were given a thorough inspection, and the engines were warmed up and given their finishing touches during the afternoon. First to get away was the NC-3, which started at 4.36 p. m., Washington time. NC-1 followed at 4.56 p. m., and NC-4 at 5.13. The boats did not make directly for the Azores but practised around the harbor to warm up their engines.

Most extensive preparations had been made by the Navy to insure the safety of the crews in case there should be any accidents. No less than 22 cruisers and destroyers were stationed on the way between Trepassey and the Azores. With a total distance of about 1200 miles, this makes only a little over 50 miles between stations.

The following is condensed from an official log on the flight, compiled by the Navy Department from reports sent in by the station ships:

NC-4 First to Be Heard From

The NC-4 took off the water at 5:36 p. m., Washington time. After having circled Trepassey harbor it alighted at 5:53 p. m. It took off the water again at 6:07 p. m., and immediately started for the Azores. The NC-3 left the water for the Azores at 6:06 p. m., and the NC-1 at 6:09 p. m. All three machines passed from sight at 6:20 p. m.

The first of the three boats to be reported from the Azores was the NC-4 piloted by Commander Read. A dispatch from Horta, Island of Fayal, under date of May 17, conveyed the information that in view of thousands of persons the NC-4 arrived at Horta Bay, having been on the way from Trepassey 15 hr. and 18 min. Both crew and machine were in first-class condition. Most of the distance was covered at an altitude of 3,000 ft., but when about 200 miles from the island of Corvo, the first island of the Azores to be sighted, Commander Read had dropped to an altitude of 1,000 ft., owing to a heavy fog. Three ships were passed on the way. The crew subsisted on sandwiches, and had no sleep during the whole trip.

The other two machines lost their bearings in a heavy fog. The NC-1 was forced to alight off Corvo Island, and the NC-3 alighted off the island of Fayal. Both of them established wireless communication with American destroyers and a search for them was begun at once.

Commander Read of the NC-4 deemed it wise to alight at Horta, rather than go on to Ponta Delgada, owing to the unfavorable weather conditions. The trip of the NC-4 from Trepassey Bay to Horta, 1,200 miles, constitutes the longest overseas flight on record. So far as representatives of the U. S. Navy at Ponta Delgada were concerned, the NC-1 and NC-3 were practically lost for 10 hrs. Then their positions were located by means of directional wireless.

After the start from Trepassey, the three machines remained close together for a considerable time, but finally the NC-4 drew ahead. The progress of the different machines, as reported from the station ships, was as follows (New York time):

NC-1 passed ship No. 2 at 7:35 p. m., No. 3 at 8:03 p. m., No. 6 at 10:05 p. m., No. 13 at 3:13 a. m., No. 16 at 6:07 a m., No. 18 at 6:14 a. m.; No. 20 at 8:10 a. m.

The NC-3, which started from Trepassey at 6:03, passed station ship No. 2 at 7:35 p. m., No. 6 at 10:05 p. m., No. 7 at 10:58 p. m., No. 9 at 12:10 a. m., No. 13 at 2:23 a. m. and No. 17 at 5:15 a. m.

The NC-4, which started from Trepassey at 6:07, passed station ship No. 2 at 7:35 p. m., No. 6 at 10:05 p. m., No. 8 at 11:29 p. m., No. 11 at 1:50 a. m., No. 14 at 3:06 a. m., No. 16 at 4:30 a. m., No. 18 at 5:45 a. m., sighted land at 7:35 a. m., passed No. 22 at 8:10 a. m., and arrived at Horta at 9:25 a. m.

No mishap or incident of any kind occurred to the NC-4 during the entire voyage and the machine was found to be in perfect condition upon its arrival at Horta.

Full moon-light favored the flight during the early part of the trip. The average speed made by the NC-4 was more than 75 miles per hour. At Horta a section of the harbor had been specially prepared for the plane. Two American destroyers were at hand, ready to assist the planes if they should alight outside of the breakwater and need assistance. Most of the American naval officers at the port remained up all night to follow the progress of the planes by means of the wireless reports. The wireless worked perfectly throughout the night, merchant ships and radio stations heeding the request of the Navy to refrain from interfering with messages regarding the flight.

At 11:40 a. m., New York time, a report was received at Horta from the NC-1 that she had been blown off her course, and had been forced to alight in the open sea, 200 miles northwest of Fayal. Four destroyers were immedi-

ately sent to her assistance. From the NC-3 a report was received at 5:15 a. m., New York time, that she was off her course between stations 17 (Destroyer Stockton) and 18 (Destroyer Craven).

The weather was fair during the first part of the trip, but heavy fogs were encountered by the NC-1 and NC-2 after passing station 17, the NC-1 being forced to descend to the surface of the ocean. The crew of the NC-1 was rescued by the Steamship Ionia, east of Flores and Corvo of the Azores group, about 110 miles west of Fayal. When a wireless was received at Horta from the NC-1 to the effect that she was lost in the fog about position 20, the destroyers Phillip, Waters, Harding and Dent were sent in search of the missing plane.

After a search lasting until well into the afternoon, the Harding got into communication with the NC-1 and reported her position. The Harding at once started off in the direction from which the signals came, at a speed of 22 knots. She reported that the wireless calls of the plane became more distinct as she approached. At the time, the Harding cannot have been so very far away from the plane, as the latter when on the surface of the water can use only her weaker radio set, the more powerful set being available only when the propellers are working and the craft is in the air.

The NC-3 had not been heard from since 5:14 a. m., at which time she was approximately 265 miles off the port of Horta.

News of the arrival of the NC-4 at Horta reached the Navy Department at 10:59 a. m. on May 17.

The first official news of the difficulty experienced by the NC-3 arrived at Washington at 11:06 in a cable dispatch from Admiral Jackson on the Melville, in which he reported that the NC-1 had passed station 19, and NC-4, station 22. In this dispatch Admiral Jackson said that the NC-3 was between station No. 16 and station No. 18 at 5:15 a.m. (Washington time) but off its course. In the same message the weather was reported to be foggy.

A report of the experiences of the crew of the NC-3 was made by Commander Towers to the Navy Department, and was given out officially on May 20. This shows that the plane was forced to alight on the ocean at 9:30 a. m. (New York time) on May 17. Commander Towers had then only 2 hours' fuel supply left, and from the time he came down until he reached Ponta Delgada his machine was buffeted by heavy seas, and was in a precarious situation for something like 52 hr.

When the NC-3 alighted on the ocean, she was about 85 miles south of the straight course between Newfoundland and the Azores. In alighting the center forward engine strut was seriously damaged, and during the trip to Ponta Delgada the machine lost both wing pontoons, the first about 4 hr. before she reached port, the second, just before she entered the harbor. Ponta Delgada was reached at 1:50 p. m. (New York time) on May 19.

In his report Commander Towers says that he was compelled to go above the clouds at station No. 8, on account of the failure of the light on the pilot instrument board, and the necessity of having the heavenly bodies for reference. The last destroyer sighted was No. 13. The plane came through the clouds at daybreak, but destroyer No. 14 was missed. Commander Towers believes that he was thrown off his course by the high velocity of the winds at the higher altitudes, but says he followed a parallel course. Heavy rain squalls were encountered at 3:45 a. m. on May 17, which continued until 9:30 a. m., when the weather cleared. At that time, after considering the fuel supply, it was decided to land and make observations.

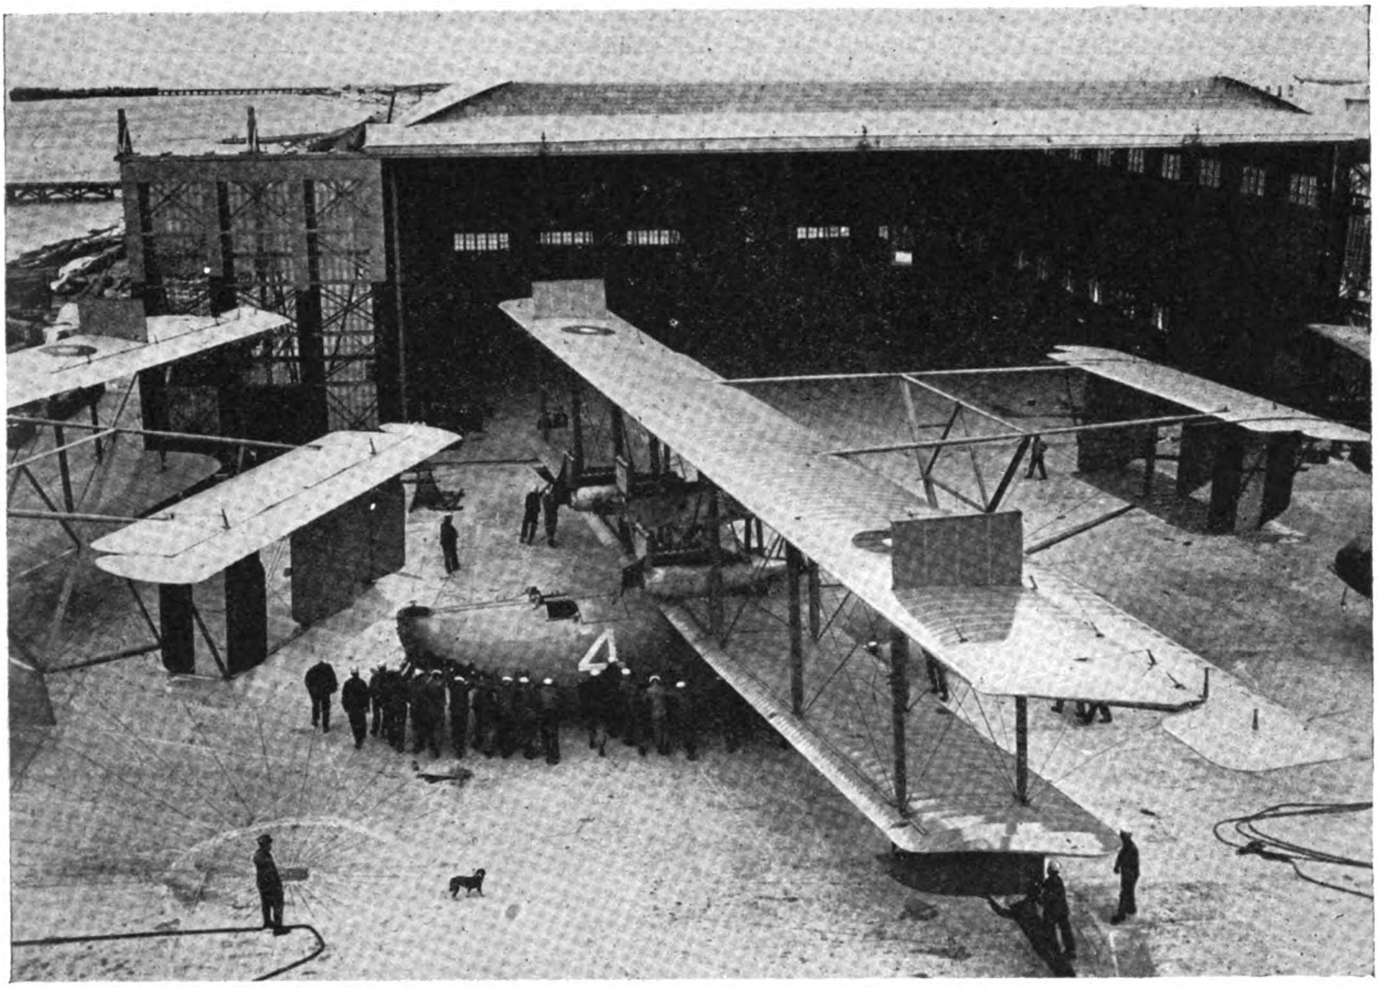
A heavy sea was running at the time, but this was discovered too late to remain in the air. In alighting, slight damage was done to the hull, but the center forward engine strut was badly damaged, and this made it impossible to leave the water again. A gale arose on the evening of the 17th, which was ridden out successfully until 5 a. m., New York time, May 19, when the port wing pontoon was lost. From the latitude and longitude given in Commander Towers' report, it is figured that he alighted on the water 90 nautical miles due south of station 22 (Destroyer Harding). This is about 95 miles from Horta and 200 miles from Ponta Delgada. The NC-3 sailed the entire 205 miles from her landing place to Ponta Delgada under her own power.

When the crew of the NC-1 was picked up by the steamer Ionia on Saturday afternoon, May 17, after they had been tossed about in the water for over 5 hr. they were greatly fatigued and suffering from sea-sickness. The plane was severely damaged by the heavy seas, and was almost a total wreck. A statement was made by Commander P. N. L. Bellinger of the NC-1 on May 19, from which we extract the following:

> The NC-1 was the last plane to take the air at Trepassey, at 6:10 p. m. (New York time). She proceeded on her course, being guided by the smoke and searchlights from the destroyers, and the star shells sent up by them. No trouble was encountered until the machine ran into a fog at

Dimensions and Characteristics of the NC Type of Flying Boats

Engines	4 Liberty
Power	1600
Span	126 ft. upper, 94 ft. lower
Length	68 ft. 3½ in.
Height	24 ft. 5⅛ in.
Chord	12 ft.
Gap	13 ft. 6 in. to 12 ft.
Wing curve	R. A. F. 6
Wings to hull	3 deg.
Engines to hull	0 deg.
Stabilizer to hull	2 deg.
Dihedral	0 deg. upper, 3 deg. lower
Wing area	2380 sq. ft. (incl. ailerons)
Aileron area	265 sq. ft.
Stabilizer	268 sq. ft.
Rudder	69 sq. ft.
Elevator	240 sq. ft.
Fin	79 sq. ft.
Weight empty	15,874 lbs.
Weight loaded	28,000 lbs.
Useful load	12,126 lbs.
Gravity tank	91 gals. capacity
Fuel tanks	1800 gals. capacity
Oil tanks	160 gals. capacity
Maximum speed	74 knots for 28,000 lbs.
Minimum speed	58 knots for 28,000 lbs.
Maximum speed	84 knots for 24,000 lbs.
Minimum speed	55 knots for 24,000 lbs.
Center of gravity	35 to 45% of wing chord
Factor of safety	3 for 28,000 lbs.



The NC-4 at its hangar

7:10 a. m. (New York time) on May 17, near station 18.

After being in the fog for some time, Commander Bellinger alighted on the water at 9:10 a. m. on May 17. The machine kept to its course until it struck the fog, when the pilot lost his bearings. It was deemed advisable to head into the wind, toward land, to take bearings before proceeding. Up to that point, the machine had been flying at an altitude of 3,000 ft., and now she dropped to 50 ft. in order to get sight of the water.

It was then found that the wind was in a different direction at the low altitude. It was also found that the fog was denser at the lower altitude. A good landing was made on the sea, which was rough and choppy, with heavy swells. The strong wind continued until the crew was picked up by the Ionia.

The mast of the Ionia was sighted at 2 p. m. (New York time), the ship being on its way to Fayal and Gibraltar. It was impossible for the crew of the NC-1 to see the hull of the Ionia, and as the vessel did not have wireless, it was impossible to communicate with her. The NC-1 therefore taxied toward the vessel, and soon they were sighted and a boat was lowered, which picked up the crew at 2:20 p. m. The position of the NC-1 when picked up was 30 deg. 15 min. longitude, 39 deg. 58 min. north latitude. An attempt was made to salvage the plane, but the tow line of the Ionia broke and the attempt was given up.

Considerable difficulty was encountered in rescuing the crew of the NC-1, as the small boat of the Ionia was tossed about like a cork. All of the crew was seasick, but otherwise they were not suffering. S O S calls were sent out by the NC-1 after alighting on the water, but the sending radius of the radio was then only 50 miles. While the crew was waiting for the rescue, they intercepted messages sent from one destroyer to another. The last radio picked up from the NC-3 was at 9:15 o'clock on Saturday morning.

Commander Bellinger stated that if the fog had not been so thick, they could have continued to Ponta Delgada. Their engines worked splendidly throughout, and the plane proceeded at an altitude varying from 500 to 3,500 ft.

Leaving Rockaway

The three NC planes of the U. S. Navy made their getaway from the Rockaway Air Station at 10 o'clock on Thursday morning, May 8. The NC-3, flagship of Commander Towers, which was piloted by Commander H. C. Richardson and Lieut. C. H. McCullough, was the first machine to start. Forty-nine seconds later the NC-1 went into the air, followed after another minute by the NC-4. The NC-1 and the NC-3 arrived at Halifax at 7 o'clock, p. m., and a report of their arrival was sent to the Navy Department at Washington by the U. S. S. Baltimore, the station-ship at Halifax. The planes made the trip of 540 nautical miles in a little less than 9 hr.

A third plane, the NC-4, commanded by Lieut.-Commander A. C. Read, had not reported at Halifax up to 8.30 p. m. Early in the afternoon, the NC-4 reported

that one of her engines was out of commission and that she was running with three engines. Later it was reported that the trouble had been corrected. Between 2 and 3 o'clock during the afternoon, the NC-4 was reported as having passed the first of the destroyers, stationed on the long lap starting at Chatham lighthouse. The machine had to make a landing at Chatham, Mass., where she was detained for several days while two of her engines were being replaced. She joined her two sister planes at Trepassey before the final "hop off."

The F-5 Navy blimp escorted the three seaplanes beyond Fire Island, and then returned to its base at Rockaway Beach shortly after 11 o'clock, a.m., on Thursday, May 8.

The second stage of the journey, from Halifax to Trepassey, was made by the NC-1 and NC-3 on Saturday, May 10. The NC-1 arrived at Trepassey at 4.14 p. m. in perfect condition after a 460-mile flight. The navigator of the NC-1 followed the precise course laid down in advance, but owing to low visibility was able to see only a few of the destroyers lining the course. The NC-3 met with a mishap on the way and had to return to Halifax, but made a second start later in the day and arrived safely late in the evening.

Hawker Not Heard From After Start

HARRY G. HAWKER and Lieut.-Commander McKenzie Grieve, the crew of the Sopwith biplane which had been waiting at St. John's, N. F., for over a month for favorable weather to cross the Atlantic, finally made off on May 19 at 1.51 p. m., New York time. No doubt the start of the NC flyers from Trepassey Bay and the successful arrival of the NC-4 at the Azores were factors in urging the British aviators to get started.

About an hour later, Frederick T. Raynham and his navigator, Capt. C. W. F. Morgan, another crew, also made an attempt to get into the air, but in trying to do so they broke the axle of their landing gear, and their machine was completely wrecked, both aviators being painfully injured. The machine which Capts. Raynham and Morgan were to pilot across the ocean was a Martinsyde.

Only about 100 persons were present when the Sopwith of Hawker went into the air. The machine ascended in spirals up to an altitude of about 2000 ft., and then Hawker flew directly east over the city, which lies 5 miles from the Mt. Pearl Airdrome, from which the start was made. Favorable weather conditions attended the start, the sky being cloudless, and only a moderate breeze blowing.

A few minutes after his start, Hawker passed Quidi Vidi Lake, alongside of which the Martinsyde Airdrome is located. As Hawker passed the Martinsyde Airdrome he cast off his landing gear, which was held on by a special tripping device to make this possible. This reduced the weight of the Sopwith by about 400 lb., and it was estimated that it would increase its speed by about 8 miles per hour. This was at once a notice to Raynham and Morgan that Hawker was off for good.

From Signal Hill, an eminence overlooking the St. John's harbor, the machine could be seen for about 10 min. longer. At the time it passed from view it was heading directly for the Irish Coast at a speed probably exceeding 100 m.p.h., as it was favored by a strong breeze.

While the weather conditions at St. John's were very favorable to the flight, those reported about the same time from Ireland were most unfavorable, there being a marked depression in that area, with rain and fog.

As Hawker and Grieve were contending for the *Daily Mail* $50,000 prize, their start had to be officially confirmed. Major Partridge, who acted as official starter, arrived at the Airdrome at 3 p. m., at which time the Sopwith had already been brought out in the open, its engine started, and everything made ready for the "hop off."

Hawker and Grieve wore heavy woolen clothing, and over that inflatable rubber suits which, it was figured, would keep them afloat for 48 hr. in case they should be thrown into the sea. They carried with them a non-sinkable boat, which was built into the fuselage of the plane, to which they intended to take in case it was necessary for them to alight on the surface of the water.

The Sopwith, with which Hawker and Grieve started from St. John's, and the Martinsyde, with which Raynham and Morgan were to make the trip, are craft of an entirely different type from the NC boats with which the U. S. Navy is making the flight. The British machines are very much smaller, and have only a single engine each. Hawker's Sopwith has a wing span of 46 ft. and an overall length of 31 ft., while Raynham's Martinsyde has a wing span of only 41 ft. and length of 26 ft. The Sopwith is equipped with a 350-hp. Rolls-Royce engine, while the Martinsyde engine only rates at 275 hp.

But while the British craft are smaller, they are speedier than the American machines. The Sopwith is rated at 100 m.p.h., and with the landing gear off she is expected to attain a speed of 106 m.p.h. Raynham's Martinsyde was a much faster machine, and was expected to make at least 124 m.p.h. with a normal load and 110 m.p.h. with the excess fuel cargo required for the long ocean flight.

Both of the British competitors intended to compete for the $50,000 prize of the London *Daily Mail*, which is for the first transatlantic flight completed in one stage, in 72 hr. It was the intention of both of the contestants to alight at the Brooklands Airdrome, near London. Commander Grieve, Hawker's navigator, expected to fly due east about 600 miles, and then turn into the transatlantic shipping lane. Capt. Morgan, of the Martinsyde, on the other hand, intended to take the direct course for Ireland, thus shortening the flight by several hundred miles.

Both navigators of the British machines relied upon their sextants and compasses for their bearings, and expected to make use of special tables in making their calculations.

At the time of this writing, Wednesday morning, no word has yet been received from Hawker and Grieve, and fears are developing that they have been lost at sea. At first there were various rumors that the Sopwith had been observed within a 100 miles of the Irish coast and another rumor was to the effect that a Sopwith machine had been observed floating on the ocean 40 miles west of the mouth of the River Shannon, but all these rumors proved without foundation. It is the belief of the British Admiralty that Hawker suffered an accident shortly after his departure, for absolutely no wireless messages were received from him, not even a farewell message.

Crowds of people waited all day Monday at the Brooklands Airdrome, where Hawker intended to land, although aircraft experts had expressed doubt that he would be able to fly the entire distance with his fuel supply. The weather off the Irish coast on Monday was boisterous, with rain and a gale.

Air Mail Service Profitable in First Year of Operation

COSTS AND REVENUES

Revenue from airplane postage		$159,700
Saving in railway transportation		2,264
Total revenue and saving		161,964
Cost of operation	$137,900	
Loss, Standard Plane No. 3, less salvage of useful parts	4,961	
Total cost of operations		142,861
Surplus		$19,103

The consolidated cost sheet for the year shows the total cost of operations of the route to be $137,900.06, apportioned as follows: Cost per mile of overhead $0.2829; cost per mile of flying, $0.2029; cost per mile of maintenance, $0.4081.

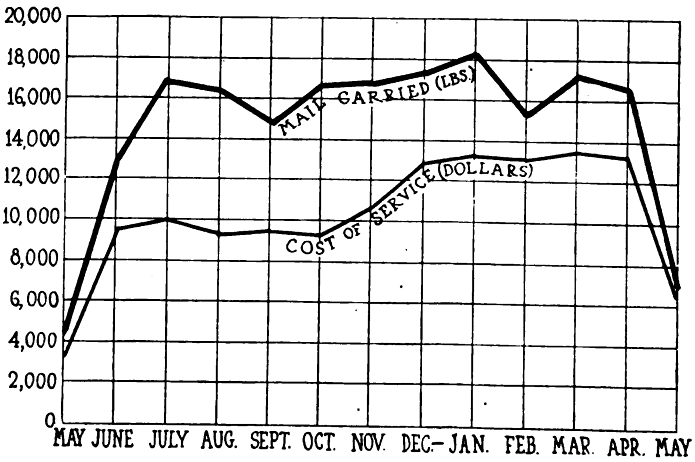
By Allen Sinsheimer

WASHINGTON, May 17—The first year of operation of the Air Mail Service between Washington and New York has particular significance because, as the first commercial aeronautical venture in this country, it indicates the possibilities of future commercial aviation, and the record of the first 12 months reveals definitely that commercial aviation is already an established fact, profitable, successful and without physical hazards.

There were no deaths resulting to the pilots carrying the mails and no instances of airplanes falling. A total of 128,256 miles was flown out of a possible 138,310 miles, 92.73 per cent of the total possible mileage. An aggregate of 193,021 lb. of mail was carried with a revenue of $159,700 and a service cost of $137,900.06. Letters carried total 7,720,840 for the year. Twenty-seven airplanes were used in the service at an average cost of $0.899 per mile each, which includes gas, grease and oil, office organization, the use of motorcycles and trucks, rent, light, fuel, power, telephone and water, miscellaneous, pilots' wages, mechanics and helpers, repairs and accessories, interest on investment, and departmental overhead. The interest on investment is a charge against the total cost of all expense incurred not including department overhead, which is considered separately. It includes a total of the cost of the planes, the landing fields, emergency fields, hangars and complete equipment.

The accompanying chart shows clearly that the commercial flying can be maintained successfully both winter and summer and that the planes can combat gales and winter conditions regardless of their severity. Starting in May, 1918, the planes traveled 78 per cent of the possible mileage, 94 per cent in June, reaching 100 per cent in September. The record fell in November and December, corresponding with the increase of severe weather, reaching a low point of 77 per cent of possible mileage performance in the latter month. The efficiency then increased gradually, despite gales of 70 m.p.h. in March, until it reached 98 per cent of the total possible mileage in May, 1919.

That the fogs, rain, snow and other climatic conditions are responsible for increased gasoline consumption and reduction of the number of miles traveled is clearly indicated by the chart, in which the curve showing the trips in clear weather, the miles traveled and the per cent of performance rise and fall together, while the trips in fogs, etc., the miles per gallon gasoline consumed, the cost of service and the forced landings rise and fall in direct contrast to the curve of the per cent of performance. Fifty-three of the trips made in January were through fog, rain and snow, at which time the mileage



Relation between mail carried and cost of service since May, 1918

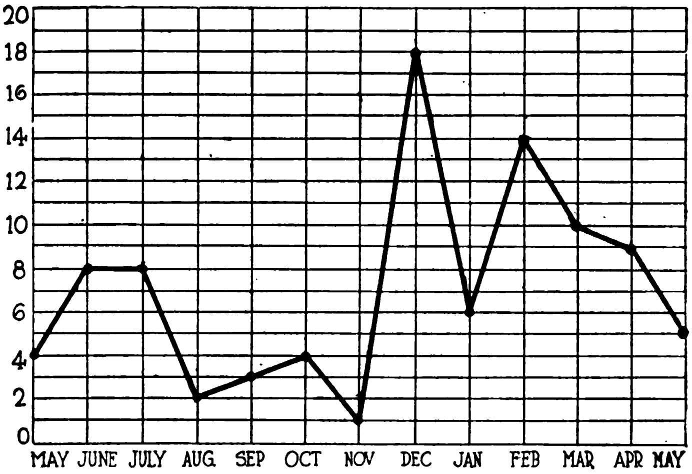
performance fell to 82 per cent, while the cost of operation climbed to $13,300.

That the engine trouble was probably the result of climatic conditions to an important extent is indicated by the fact that it occurred chiefly at the same time with the forced landings caused by the weather.

Three types of airplanes have been used in the service, including the Standard, JNRI, the Curtiss and the De Haviland 4 army airplane, which was reconstructed and adapted to mail carrying. Each of the first two was equipped with engines of 150 hp. and the De Haviland with the 400 hp. Liberty engine. The reports indicate that the power of the Liberty engine was found necessary to combat the heavy gales. The 150 hp. engines were unable to achieve a speed over 37 m.p.h. in the face of the high winds.

Of 1261 possible trips, 1206 were undertaken and fifty-five were defaulted because of weather conditions. Four hundred and thirty-five trips were made successfully during rain, fog, snow, gales and electrical storms. Fifty-one forced landings resulted on account of the weather and thirty-seven because of engine trouble. The Department believes that these forced landings have demonstrated that the airplanes, as designed for the army, lacked the strength necessary for daily cross-country work.

It was necessary early in the operation of the service to determine if visibility is essential to commercial flying. The first step was the refinement of the existing radio direction finders to eliminate the liability of 3 to 5 per cent of air. This was worked out by the Navy Department on an air mail testing plane. The second problem was that of guiding the mail plane to the center of the plot for landing. This problem has been solved by the Bureau of Standards in experiments with the radio directional compass, which is now effective to an altitude of 1500 ft. and by further refinements will be made efficient for 2500 ft. The year's flying in the mail service has established the fact that 200 ft. visibility from the ground is the limit of practical flying, although in emergencies flights have been made at altitudes as low as 50 ft.



Number of forced landings due to weather and engine trouble

The distance between Washington and New York by air is 218 miles and has been covered in 1 hr. 58 min., while the distance between New York and Philadelphia, which is 90 miles, has been covered in 48 min. Speed averages have reached as high as 110 m.p.h., while against the severe gales of last March they were held down as low as 51 m.p.h.

Several of the planes, of the Curtiss and Standard makes, have records of 200 flying hours and 14,000 miles of flying each. Records of flight include 191 legs of the New York-Washington route by Dana De Hart, who covered 21,360 miles and made 179 of the legs and 20,324 miles without a forced landing. Max Miller flew 82 legs covering 9,242 miles without forced landing or an uncompleted flight. The service was under the control of army aviators during the first three months of operation, and was then taken over by the Post Office Department and was operated by a civilian organization.

Following is the complete report of Second Assistant Postmaster General Otto H. Praeger, who is in charge of the Air Mail Service, containing complete tables of the cost and the performance for the year:

Report on AIRPLANE MAIL SERVICE

Washington-Philadelphia-New York Route, for Year of May 1, 1918, to May 1, 1919

POST OFFICE DEPARTMENT,
Office of Second Assistant Postmaster General,
Washington, D. C., May 15, 1919.

The Postmaster General:

One year ago to-day the Aerial Mail Service was inaugurated by your direction, with instructions that once installed it must remain a permanent and practical feature of mail transportation. The first year's operation of this service has vindicated the judgment of the Department in entering upon this work.

At the request of the Chief Signal Officer of the Army, the operations of the Aerial Mail Service were originally conducted by the Army in connection with its work of training aviators for the war. This service continued under military direction until August 10, when, by agreement with the Secretary of War, it was taken over by the Post Office Department and operated by an entirely civilian organization.

A single route from Washington to New York was established, though much incidental work was done with reference to the extension of the service to other parts of the country as soon as sufficient equipment became available. This

Consolidated Statement of First Year's Operations of Air Mail Service

Month	Trips Possible	Trips Attempted	Trips Defaulted	Weather Encountered		Mileage Possible	Miles Traveled	Per Cent of Performance	Mails Carried (Pounds)	Cost of Service	Forced Landings Due to

preparatory work related to the establishing of a second route from New York to Chicago, an air-line distance of 720 miles across the Allegheny Mountains and the southernmost points of Lakes Erie and Michigan

Trial flights were made to establish the practicability for commercial work of the De Haviland 4 airplane, which became available upon the signing of the armistice, but it was found that this plane, designed wholly for war purposes, lacked the strength necessary for daily cross-country work, with its incidental forced landings. It was then decided to modify these war planes, and, after some delay, aeronautical engineers have developed a strong and powerful plane which can still retain all the excellent flying qualities of the De Haviland machine.

The principal work of the Aerial Mail Service, however, concerned the operation of a daily air-mail service between Washington and New York, a distance of 218 miles air line. A great divergence of opinion existed among aeronautical experts as to the possibility of the Post Office Department keeping up anything approaching a daily service, regardless of weather conditions. The opinion was held that the service would have to be given up during the winter months. However, the postal authorities and the aeronautical experts retained by the Post Office Department believed that practically all of the weather conditions could be overcome, and that possibly 90 per cent of the trips scheduled could be entered upon. How well this judgment has been borne out is shown by the fact that out of a possible 1263 trips, only 55 were not undertaken and utterly failed on account of weather or other conditions requiring the sending of the mail by train. This is a record of only 4.4 per cent of trips not attempted. Out of a total 138,310 miles possible there were flown 128,255 miles, which is a performance of 92.73 per cent. Such performance for a single motor training plane was not believed possible when our service began, and has never been equalled in the history of aviation. It should be explained that the airplane journey from Washington to New York and return, daily, is made in four trips, as follows: Washington to Philadelphia; Philadelphia to New York; New York to Philadelphia, and Philadelphia to Washington, mail and—when necessary—pilots and planes being exchanged at Philadelphia.

In the year's operation an aggregate of 128,255 miles was flown, and an aggregate of 193,021 lb. of mail was carried, the cost of operation of this route being $137,900.06. It may be well to state here that the same six airplanes that entered upon this service a year ago to-day, with the same engines that operated them, are on the flying fields on this date, rendering a continuous service, and the mail to-day from Washington to New York and New York to Washington will be carried in the same airplanes that made the initial flight from Potomac Park on May 15, 1918, and that brought the mail from New York on that day. This operation has cast a new light on the question of the life of an airplane, and demonstrates that the mechanical requirements and results in commercial flying are much safer, much more economical, and in many instances more practical than in exhibition or military flying.

During the year there have been 37 forced landings, due to mechanical troubles during flight, which is another record not heretofore approached in aviation, and speaks well for American-built airplanes and the mechanics who were engaged to keep them in flying condition. Especially is this record a strong tribute to the American-built Liberty and Hispano-Suiza motors.

In field work, in testing out of planes by aviators, there has been one serious injury, when an aviator smashed a plane, resulting in the gas tank catching fire on the ground. In this accident the pilot was severely burned, but was able to report for duty at the end of four weeks.

The New York-Washington Air-Mail Service, while undertaken as a permanent transportation improvement in the carrying of mail, was, during its first year, largely an experimental proposition. Inaugurated before the close of the war, it was possible to obtain only small training planes with a limited capacity for carrying mail. It had to be established first that a daily, fairly dependable schedule could be maintained. Exploration and experiments had to be made to properly equip the planes to fly regardless of weather conditions and of visibility. The route was but 218 miles in length, and the cost of operations of this route had to bear the entire cost of adapting the war machines and training machines to commercial work as well as the cost of the experimental flying and the experimentation with devices that would enable flying in all kinds of weather. Under the circumstances, the cost of the service would naturally be higher than it should be the subsequent years of operation, with the expense problems connected with experimental flying solved. Likewise, the cost per pound of mail carried in the larger planes which are now available will be much less than the cost of carrying the mail in planes of but 200 lb. mail capacity.

Costs and Revenues

Revenue from airplane postage		$159,700
Saving in railway transportation		2,264
Total revenue and saving		161,964
Cost of operations	$137,900	
Loss, Standard Plane No. 3, less salvage of useful parts	4,961	
Total cost of operations		142,861
Surplus		$19,103

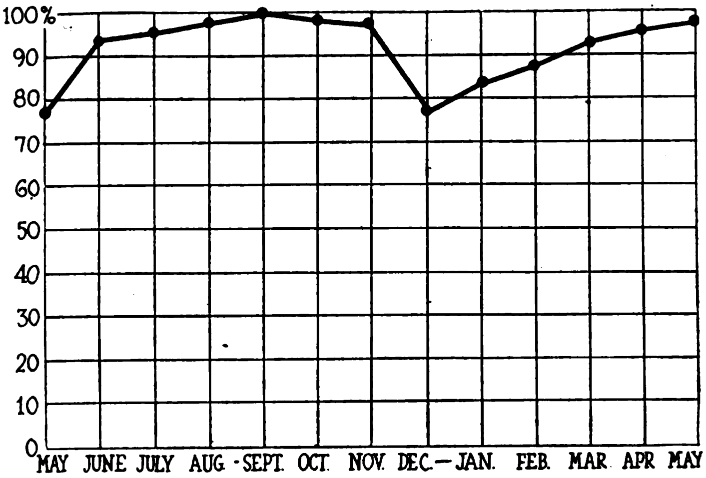
The consolidated cost sheet for the year shows the total cost of operations of the route to be $137,900.06, apportioned as follows: Cost per mile of overhead, $0.2829; cost per mile of flying, $0.2029; cost per mile of maintenance, $0.4081.

The revenue on the sale of airplane stamps was $159,700. In addition to the airplane mail there were carried several million ordinary letters taken from railroad connections,

which were advanced in delivery by airplane over train from twelve to eighteen hours. This improved service involved millions of letters delivered by reason of airplane service in New York in the afternoon, instead of on the following morning had they gone by train, which alone justifies from a postal standpoint the operations of the service.

The postal value of an airplane service depends upon the distance covered and upon railroad schedules. There is not sufficient business between New York and Washington of such an urgent nature as to pay out through airplane postage alone the cost of operations. The distance is too short and the train service too efficient to warrant the use on a large scale by commercial interests of airplane service in lieu of the train service. The transportation by airplane is ordinarily twice as fast as by train, and on distances of 600 miles or more, no matter how frequent or excellent the train service, the airplane mail at the higher rate of postage should equal the cost of its operation. Wherever the train service is not as frequent or as fast as it is between Washington and New York the airplane operations should show an immense profit on all distances from 500 miles up.

Again, with large airplanes and over greater distances, substantial reduction in the sums paid to railroads for mail transportation would be made, besides cutting down the time of transit by one-half.



Per cent of possible monthly mileage flown since May, 1918

New York-Chicago Route Most Promising

The most promising of such routes is the run from New York to Chicago. An airplane leaving New York at 5 a. m., traveling at the rate of 80 m.p.h., with 15-min. stops for mail and exchange of planes at Bellefonte, Cleveland, and Bryan, will reach Chicago before 2 p. m., Chicago time, thereby insuring connection with the afternoon regular carrier delivery. Such an airplane dispatch, by reason of the great service rendered, would give a handsome profit on operations.

The first leg of the New York-Chicago route will be opened with our rebuilt De Haviland airplanes to-day from Cleveland to Chicago, and the remainder of the route from New York to Cleveland will be opened as soon as the necessary Curtiss R-4 mail ships are delivered to us by the factory, which should be within the next thirty or forty days.

One positive lesson learned from the operation of the aerial mail during the year is that the element of danger that existed in training aviators in military flying and exhibition flying is almost entirely absent from commercial flying.

The record of the Aerial Mail Service, which includes flying at altitudes of as low as 50 ft. in periods of marked invisibility, throws an interesting light on the dangers of aviation. In a period of one year, covering a travel of 128,255 miles, there has never been an airplane carrying the mail fallen out of the sky; there has not been a single death of an aviator in carrying the mails. The casualty record for the year comprises two deaths. One of these was in the case of an aviator who undertook to give a demonstration of his flying ability before being given a plane to carry the mail. He went up in a De Haviland 4 and showed by his management of the plane that he was not qualified for the work. He put the plane in a vertical stall at a low altitude and crashed to the ground, killing himself. The second casualty was that of a mechanic who slipped and fell into a whirling propeller of a machine that was on the ground.

There have been six injuries to aviators of a minor character and two serious enough to send the aviators to the hospital for a period of several weeks each. All of these accidents occurred, not in the air, but while on the ground. Of the minor injuries, the aviators were in a position to report for duty on their next run. These injuries consisted mainly of bruises or contusions sustained by a plane turning over after it had landed on the ground. Of the three types of planes operating regularly in the mail service, one type was more given than the others to turning over on rough ground, and it was principally on those planes that the pilots were shaken up or bruised by the plane turning turtle.

The first serious accident, which resulted in a hospital case

of several weeks, occurred to a pilot driving a De Haviland 4, the axle of which crumpled after the pilot had touched the ground and had run some distance along the surface.

The other accident was in the case of an aviator who started up to try a motor that had gone through the block test, and at 150 ft. elevation it began to miss. Not desiring to take the chance of landing on rough ground, he undertook, what nobody has ever been able to accomplish with a De Haviland, that is, to turn around and land in the center of his field. The turn naturally killed his speed and he slipped to the ground in a side slip. The plane struck partially on a wing and partially on the radiator nose, driving the engine into the air-pressure tank, which squirted a spray of gasoline that caught from the exhaust and sent the machine in flames while the plane was on the ground. The aviator jumped through that flame and his clothing caught fire and he was burned about the face and hands.

One Death for Every 64,108 Miles Flown

Of one type of machine in the mail service, which has performed almost half of the amount of work of the other two types, there has never been a case, by reason of the construction of the machine, of turning turtle. This record means, taking into account all of the accidents, whether on the ground, testing machines, testing aviators, flying the mail, or other cross-country work, that there has been but one death for each 64,018 miles flown—one serious accident in each 64,018 miles, and one minor hurt for each 21,340 miles. This is a record which will compare favorably with any mode of mechanical transportation in its early days. Even this favorable record is susceptible to improvement by reason of the steady development of the airplane itself.

The following is a chronological list of accidents and deaths in the Aerial Mail Service for the year just past:

Sept. 10, 1918—Ed. C. Radel, mechanic, plane No. 39367; turned over and completely wrecked on return experimental trip from Chicago to New York; Radel pinned under plane; motor fell on him, injuring arm somewhat, and burning back with gasoline; 10 miles from Belmont; taken to hospital for treatment, but out next day. Edw. Gardner, pilot (Chicago-New York reconnoissance); nose had been broken a short time before; this fall shook it loose again and gave him a black eye.

Oct. 18, 1918—M. A. Newton, pilot, plane No. 39366, Philadelphia to Belmont; four miles from Belmont engine went dead, gas pressure failed, and dropped plane in deep hole which was so covered with dust and weed-filled that it looked to be solid ground; thrust pilot forward, breaking his nose; flew next day.

Dec. 16, 1918—Carl B. Smith, pilot, making demonstration flight to show ability to fly; plane No. 39464, DH-4; machine in perfect condition according to test-out before; Elizabeth, N. J.; plane fell directly to earth, killing pilot instantly; observation made that if pilot's seat had been in the rear cockpit where the mail compartment was he might have been saved, as that part of the plane was undamaged; pilot crushed almost beyond recognition.

Dec. 28, 1918—Lyman W. Doty, pilot, injured in accident at Belmont Park; plane No. 24238, DH-4, demolished; faulty axle; machine of too soft wood; crumpled like an eggshell when the axle of the plane gave way; this pilot would not have been injured if pilot's seat had been located in the rear where the mail chute is placed instead of directly between the engine and gas tank.

Jan. 7, 1919—Auguste Thiele, mechanic, while starting propeller of plane No. 4, slipped and fell in front of blade, fracturing skull, at Belmont Park; accident occurred at 3.20 p. m.; Thiele in hospital at 4.40 p. m.; died at 6.14 p. m.

March 19, 1919—L. D. Smith, pilot, plane No. 8, Tottenville, Staten Island, N. Y.; Smith's nose broken; heavy wind brought him down; nothing wrong with motor; broke landing gear, propeller, and wing.

April 26, 1919—Paul Ferron, plane No. 68, DH-4, Belmont; pilot started up to try a motor which had gone through the block test, but it missed at 150 ft. Not desiring to land on rough ground, he turned around to land in the center of the field, killing his speed and slipping to the ground in a side slip; plane struck partly on wing and partly on radiator nose, driving engine into air-pressure tank, which squirted a spray of gasoline that caught fire from the exhaust and sent the machine in flames; pilot jumped through flames clothing catching fire, and receiving burns about face and hands; in hospital several weeks.

In the course of the year a number of severe gales were encountered and a few trips failed through experimenting with different types of planes to meet the gale conditions. Out of the experience this lesson was learned: It is useless to send

Variety in Design Emphasized by Sketches Shown—Spokes Made of Round and Flat Bar Stock and of Pressed Steel—Plain, Flanged and Corrugated Rims

By P. M. Heldt

TRACTION engine wheels have been in use for many decades, and it might be supposed that their design had been fairly well settled. This, however, is far from correct. It must be remembered that previous to the advent of the gas tractor the number of traction engines manufactured was limited and there was not that competition among parts makers to improve their product, and thus secure for themselves a bigger share of the market, which we are witnessing to-day. All improvement in wheels tends toward decrease in weight without loss of strength and toward a lessening of the cost of manufacture.

Tractor wheels must, of necessity, have comparatively large diameter, and this seems to almost preclude the all-cast wheel. The rims are rolled of either flat or angle steel, the hubs are cast and the spokes, which are of either flat or round section, are riveted to the rim and either cast into the hub or riveted to flanges thereon. All wheels have two rows of spokes, and in order to secure lateral rigidity these spokes must slant considerably. The driving and braking torque is not transmitted through the spokes, and the latter therefore may be arranged radially.

The sketches illustrating this article were drawn by an AUTOMOTIVE INDUSTRIES artist at the Kansas City tractor show and represent practically all the different designs of wheels at present in use. One of the sketches shows the Fordson front wheel. The rim of this wheel is rolled up out of two steel angles, and the flat spokes are riveted between the two outwardly extending flanges of the angles which form the skid ring. The outer ends of all spokes are thus in the same plane, and this gives considerable inclination to the spokes, insuring great lateral rigidity without an unduly long hub. The inner ends of the spokes are cast into the hub.

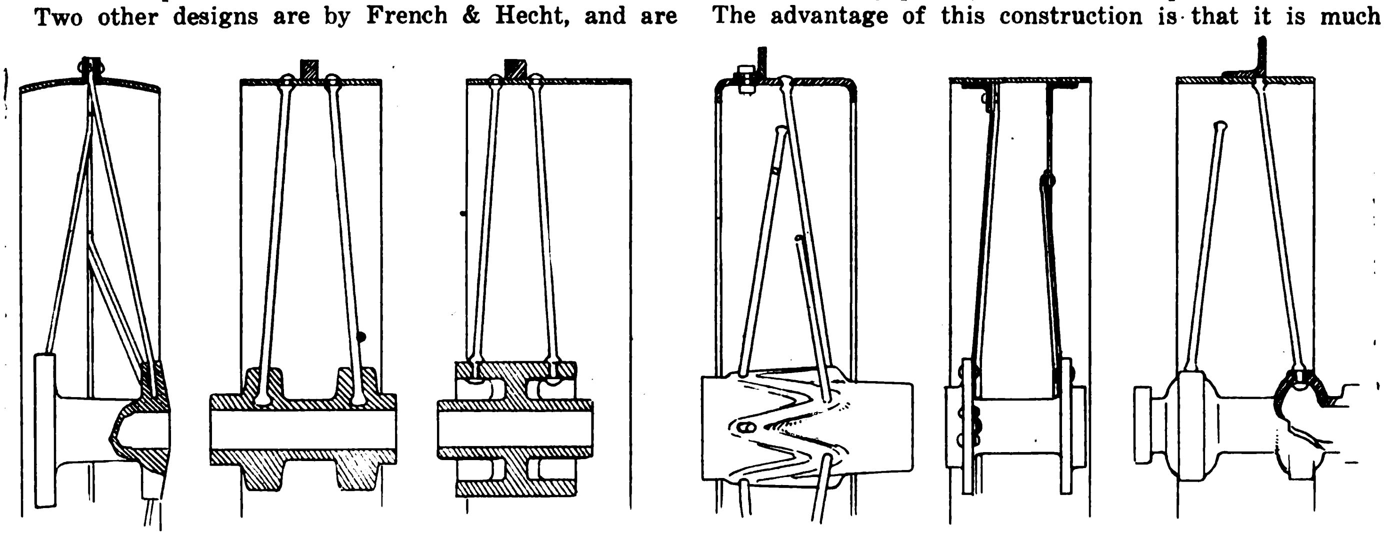
Two other designs are by French & Hecht, and are standard traction engine wheels. Both have plain rims, and the round spokes are cast into the hub, being anchored in circumferential flanges in one instance and in a sort of rim in the other. It does not appear that there is much difference between these two designs of hubs as regards weight of metal. Plain skid rings of square cross-section are shrunk on to these wheels.

Another sketch shows the Hart-Parr design of front wheel. This has an inwardly flanged rim, a construction which gives light weight without unduly reducing the structural strength. The sketch bears witness to the effort of the designer to reduce weight to a minimum. In order to gain plenty of lateral strength, the spokes are all brought to the same central line on the rim, and are given a considerable slant. To secure a firm anchorage of the spokes in the hub, the latter is cast with a zigzag flange, the spokes entering the hub at the turning points of the flange. In this wheel an angle-iron skid ring is used, which is bolted to the rim.

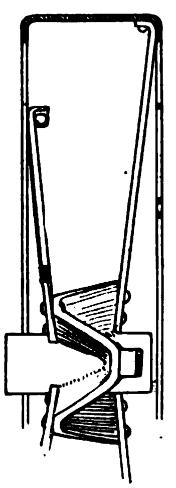
The J. I. Case T. M. Co. wheel has a plain rim with two angle-iron rings riveted to the inside, to which the spokes are riveted. The spokes are made of pressed steel, with a corrugation running down the middle, and appear to be very light. This is the first sketch to be shown in which the spokes are riveted both to the rim and to the hub. There are flanges of ample depth on the hub, which facilitate the riveting.

The Russel front wheel has round spokes cast into the hub and riveted into the plain rim. An angle-iron band serves as a skid ring. The hub is somewhat unusual, in that it is chambered out where the flanges for the spokes come.

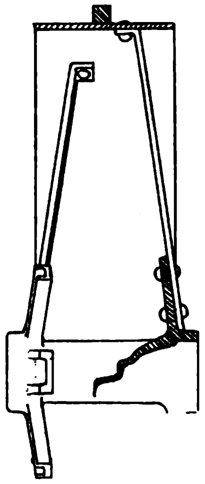
The wheel of the new Twin City tractor has the hub formed with a moderately deep zigzag flange, with flats at the turning points, to which the spokes are riveted. The advantage of this construction is that it is much



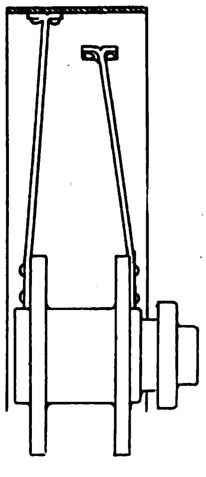
FORDSON (Front) WISCONSIN SANDUSKY HART-PARR CASE RUSSELL



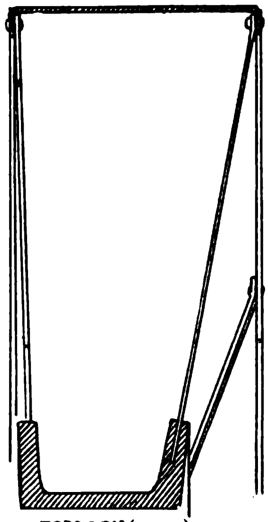
TWIN CITY



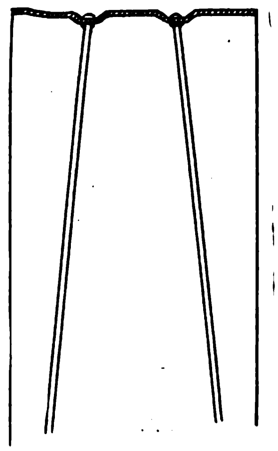
AVERY



LIBERTY



FORDSON (Rear)



VELIE

easier to hold the heads of the rivets in riveting the spokes in place than where there are two flanges. As the two rows of spokes are comparatively close together at the hub, they are arranged to spread outwardly toward the rim, and they are riveted to the rim just inside the inwardly turned flange. The Avery front wheel has a cast hub with spurs to which the flat spokes are riveted. The spurs are quite long, and are formed with a depression, in which the flat spokes fit, and there are two rivets in each spur.

The wheel of the Liberty tractor has flat spokes with Tee heads riveted to the rim, and a cast hub with deep flanges to which the spokes are riveted on the outside. There are two rivets through the inner end of each spoke.

The Fordson rear wheel is similar to the Fordson front wheel, except that the two rows of spokes, instead of approaching, recede from each other in passing from the hub to the rim, and the outer ends are riveted to the inturned flange of the wheel rim.

The rear wheels on the new Velie tractor have corrugated rims. The wheels are of French & Hecht make, and the idea of the corrugation is to strengthen the rim.

The Liberty Ignition Magneto

ENGINEERS of the Berkshire Magneto Co., Pittsfield, Mass., have developed a high tension, inductor type magneto which is mechanically interchangeable with the distributor heads forming part of the battery ignition system used on the Liberty aircraft engine. This magneto will be marketed as the Liberty.

In appearance the magneto closely resembles a small electric motor, as it is cylindrical in form, measuring 6½ in. in diameter by 7¾ in. in length. The weight is less than 17 lb. Briefly described, the magneto consists of a cylindrical aluminum frame within which is mounted an aluminum field casting with four sets of laminated steel inserts for pole pieces. The four poles of the field are not symmetrically arranged, as in standard practice, but are located so that the distances between the centers of adjacent poles are alternately 67½ and 112½ deg. apart, these angular spacings corresponding to the intervals between successive explosions in the engines. This arrangement insures that all sparks occur at corresponding points of the voltage wave, thus insuring substantially equal intensity of all sparks.

Secured to opposite sides of the field casting are two nearly semicircular magnets of tungsten steel, the ends of which abut each other in the center of one pair of pole shoes. The primary and secondary coils of enamel-insulated wire are wound on a laminated core. After final assembly the entire unit is thoroughly impregnated with a special compound in a vacuum.

A two pole rotor, arranged for four sparks per revolution, built up of steel punchings and assembled on a one-piece, hollow steel shaft, is carried on two substantial ball bearings,

one of which is rigidly mounted in a flange on the inside of the main frame, while the other is pressed into an aluminum plate, secured to the outer end of the field casting, which also serves to carry the interrupter and condenser.

The interrupter, which is of exceptionally light design, is operated by a self-lubricating cam, so designed as to provide for the irregular spacing of explosions.

The distributer is of the gap type, made of a molded compound, with metal inserts and socket type, radial receptacles for the leads from the spark plugs, the terminal binding screws being on the inside. This distributor also serves as the end cover of the magneto, and when removed exposes the interrupter, condenser, coil and other vital parts, which are thus easily accessible for inspection or repair.

Power is transmitted from the camshaft of the engine to the rotor through a flexibly mounted train of gears, comprising a large bronze annular gear and three steel pinions, which latter engage with a hardened steel pinion on the rotor shaft, causing it to turn at three times camshaft speed. A sheet metal cover incloses the side of the frame and together with the distributor on the end forms a water and dust proof protection for the working parts of the magneto.

Newest Type of Zeppelin Cruiser

ALL the latest improvements that the Germans had achieved were embodied in a Zeppelin which made a forced landing in France in October, 1917. Since that time no change has taken place in any essential feature. In length the airship is about 656 ft., the total height 79 ft., and its volume 2,000,000 cu. ft. In form the central portion is cylindrical, and the two ends taper to a cone. Of the four gondolas one is placed well forward. This is divided into two compartments, in one of which there is the commander's cabin and the wireless telegraphic apparatus, while in the other the motor is fixed. Approximately amidships, side by side, are two other gondolas, each of which is also furnished with a motor. The fourth gondola, situated close to the tail, contains two engines, one of which is held in reserve for emergencies.

A triangular passage is built into the lower part of the envelope and is completely covered in. A ladder connects the gondolas directly to this passage. A wooden construction in the center of this passage contains the fuel, the water ballast, the bombs, and several hammocks. A cylindrical chimney, constructed of a series of metal rings, connects this passage to a platform on the top side of the airship, where machine-guns and other light weapons are stationed. The four gondolas are well streamlined. The most forward of these is 32.8 ft. long, 20 ft. of which is taken up by the cabin of the commander. In height this chamber is 8.2 ft. and in breadth 7.4 ft. The motors develop approximately 1200 hp., while the diameter of the four propellers is 16 ft. The fuel tanks are of aluminum, and hold 80 gal.

The water ballast tanks have a capacity of 265 gal. The normal speed of this airship amounts to 62 m. p. h., while journeys of 30 hours' duration were undertaken without any difficulty. With a good climbing capacity the airship can attain heights of 18,000 to 20,000 ft.

Flowmeters and the Calibration of Carbureter Nozzles*

Experimental Work on Carbureter Nozzles in Respect to Gasoline-Flow Calibration—Development of a Standard System of Carbureter Nozzle Calibration by Gasoline Flow

By Capt. G. Smith Clarke

PREVIOUS to July, 1915, as far as the author is aware, it was the universal practice of carbureter manufacturers to define the size of their carbureter nozzles as the size, in inches or millimeters, of the drill used to produce the orifice. This system, however, did not give that interchangeability of the nozzles, from a carburetion standpoint, which it was undoubtedly intended to do. For instance, let us suppose that an engine fitted with a duplex carbureter was giving satisfactory results when two nozzles marked 1.70 mm. were fitted. There was then absolutely no guarantee that another engine and carbureter, similar in every respect as far as is possible, would give anything like similar results when fitted with two other nozzles also marked 1.70 mm.; or, further, let us again suppose that such an engine when fitted with nozzles marked 1.70 mm. showed obvious signs of weak mixture, then again there was no guarantee that nozzles marked 1.80 mm. would pass more gasoline; in fact, as will be shown later, it was frequently found that nozzles marked 1.60 mm. passed more gasoline than those marked 1.80 mm. when tested under similar pressures. This condition of affairs created the impression that there was some mysterious "individuality" among gasoline engines, even when they were practically identical in capacity, design and workmanship. Subsequent developments have proved that much time, labor and materials were needlessly expended in trying to cope with this supposed "individuality," which in the majority of cases was really due to the "individuality" of the carbureter nozzles.

It is believed that the first investigations into the behavior of carbureter nozzles as commercially manufactured were carried out by Lieut. B. Humphrey, who, about 1905, when assistant manager of the Great Western Railway Motor Car Department, instituted a system of nozzle calibration by gasoline flow.

The apparatus first used is shown in Fig. 1, and consisted of a length of ½-in. gage glass tube, to one end of which was fitted an adapter to take the carbureter nozzle to be calibrated. At two points, as shown on the diagram, datum lines were made on the tube, 10 in. apart, and the number given to the nozzle was the number of seconds required to pass the quantity of gasoline between these points.

The method of using this instrument was for the operator to hold the tube vertically, nozzle downward, and, closing the nozzle orifice with his finger, to fill the glass tube with gasoline; the nozzle orifice was then uncovered, and as the top of the gasoline column passed the first datum point a watch was started, being stopped as the column passed the bottom datum point. Such a method was obviously crude and liable to serious error, but the results obtained were such as to fully justify the development of the system, and it may be stated that from the date of these early experiments until the present day the size of all nozzles used by the Great Western Railway Motor Car Department has always been designated by a figure representing discharge under fixed conditions. In 1909-10 it was decided to standardize a system whereby all nozzles were calibrated under a constant head of 100 cm., the number stamped upon the nozzles representing the quantity of gasoline in cubic centimeters passed in unit time, which was fixed at one minute.

The instrument used for this system of calibration consisted of a 1-in. brass tube a little over 100 cm. in length, fitted at the lower end with an adapter to take the nozzles to be calibrated, and provided with a valve to control the flow of gasoline. At the upper end a float feed mechanism was fitted, which maintained a constant level of gasoline in the tube 100 cm. above the nozzle orifice. This, it is confidently believed, was the father of all constant-head nozzle calibrating machines, and upon this system has been based the system now standardized by the Aeronautical Inspection Department and the Royal Air Force.

Concurrently with the nozzle calibration experimental work described, efforts were made to produce a simple gasoline flowmeter for the determination of the gasoline being consumed during engine testing. The usual method of measuring consumption by timing a given volume of gasoline is liable to serious error, its accuracy depending entirely upon the personal element, while to run one hour or even half hour consumption tests is wasteful and expensive. After much experimental work and many failures, a satisfactory instrument was evolved. This will be fully described later.

In July, 1915, when the author first became interested in

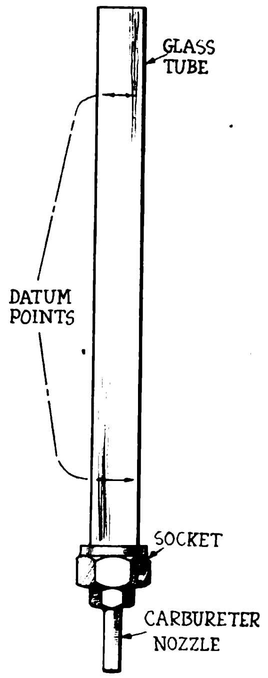

Fig. 1—Early device for determining flow characteristics of carbureter nozzles

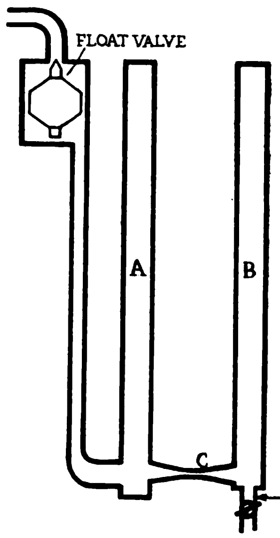

Fig. 3—Diagram of flowmeter type of instrument

*Paper presented to the Institution of Automobile Engineers, condensed.

the inspection and running tests of aero engines, the 80-hp. Gnome and the 90-hp. R. A. F. were the engines built, both being air-cooled and therefore very sensitive to variations in the strength of the explosive mixture. The Gnome engine was fitted with a floatless carbureter having a multi-orifice nozzle, the actual gasoline flow being controlled by a simple stopcock between the nozzle and the fuel supply. As may be supposed, very careful adjustment of the stopcock was needed to get the engines through their tests, on the fuel consumption demanded, without damage to the steel cylinders through overheating, and it was quite the usual thing for an engine to do several official test runs before the tester hit upon the correct adjustment.

The 90-hp. R. A. F. engine was fitted with a duplex carbureter having two diffuser nozzles, and it was a very difficult job to get these engines through the official test, one engine often taking several days. The troubles experienced were overheating, failure to obtain the required fuel consumption, erratic running and bad distribution. These troubles were usually attributed by the manufacturer's staff to insufficient cooling, and to "dud" magnetos, but it was always the opinion of the author that the great majority of them were due to bad carburetion. Reaming of nozzles was officially prohibited, since it was obvious that the nozzles must be interchangeable in the field by makers' numbers; after changing nozzles it was necessary to run the engine for at least half an hour before the result could be seen, and if, as frequently happened, the engine during the run had been getting a weak mixture, overheating had dried up the pistons and damaged the piston rings, which would not be detected until several tests had been run, the engine getting steadily worse and finally refusing to give the required power. It would then be taken off the test bed and overhauled, after which the whole process would be repeated, until by a lucky shot a pair of nozzles were found which gave the required results, and the engine was passed off test amid general rejoicings.

Irregularities in Operation Traced to Nozzle Sizes

Finally the conclusion was reached that carburetion was really the root of the trouble, and investigations were made into the characteristics of the carbureter nozzles as supplied by the manufacturers. Tests carried out with a small tank, a glass measure and a stopwatch showed that it was quite impossible to take the maker's number as an indication of the quantity of gasoline which the nozzle would pass under given conditions. As the result of these investigations, an instrument was made for the calibration of nozzles under a constant head. The instrument previously described was copied, except in the matter of the actual head used. This, in view of the fact that the nozzles used in the aero engines were very much larger than those used in car engines, and also that the instrument might be reduced in size, was fixed at 50 cm. The timing mechanism was incorporated as an integral part of the instrument and inter-connected with the control valve.

A large number of jets of various makers' sizes were then taken from the stock of an engine contractor, and these were very carefully calibrated; the new number, which represented quantity of gasoline in cubic centimeters per minute passed under a constant head of 50 cm. was tabulated against the original maker's number, the results of these experiments being shown in Tables I and II.

These figures confirmed the previous conclusion that the maker's number had practically no connection with the actual nozzle size, and it was decided that all nozzles in stock at the works of various engine contractors must be recalibrated, but as the engine testers and the R. F. C. personnel were accustomed to think of nozzles in maker's numbers, it was at this juncture decided that such numbers must be retained, a flow of value being fixed for each nominal size.

Time instruments were installed at the works of the carbureter makers, and nozzles began to come through which could be depended upon to some extent. The result of this was that conditions in the engine-testing shops showed great improvement, and engines were got through acceptance tests with very much less trouble. A little later, upon the introduction of other makes of carbureters, it was finally decided to drop drill sizes entirely and to adopt the gasoline flow figure as the nozzle size. This was known as A. I. D. Standard Jet Calibration System, Mark 1, the sizes indicating the flow of gasoline through the nozzle in cubic centimeters per minute, under a constant head of 50 cm., using gasoline of S. G. 0.700 to 0.750, at a temperature of 50 deg. F.

Nozzle Calibration Eliminates Carbureter Tuning

With every type of engine using non-adjustable nozzles, it has been possible to fix the nozzle sizes for use on test and in flight, and with very few exceptions all the engines of any one type have been tested upon nozzles of the fixed size without any carbureter tuning whatever, while in the very few exceptional cases the necessary change has not exceeded plus or minus 15 per cent, the extreme variation only being found in the case of nozzles of the diffuser type.

All engines have been dispatched from maker's works fitted with the standard size flight nozzle for its particular type, and in this case again, with very few exceptions, the machines have passed the flight test, and have been put into service without alteration of nozzle size.

In the comparatively few cases where it has been necessary to change the flight size nozzles this has usually been eventually traced to variations in the design or position of the air intake pipes fitted after the engine has been installed in the aeroplane.

In the case of rotary engines having carbureters fitted with adjustable nozzles, a very interesting instance of the value of "gasoline flow" calibration has been experienced. On what is believed to be the most powerful rotary engine which has been built in quantities, a carbureter was fitted in which the nozzle size was controlled by a taper needle connected to the throttle slide; this had been adapted from a smaller edition of a similar type of carbureter, and the needle valve was very far from satisfactory. Once a carbureter was corrected to suit the engine all other carbureters were

made uniform and interchangeable with it, by calibrating each one on a specially adapted flowmeter, at several positions of throttle opening. So satisfactory was this method that when shortage of carbureters rendered this necessary engines were despatched without carbureters, to be followed when supplies permitted by carbureters which had been calibrated, but which had not been tested upon engines, and in every case these functioned correctly when fitted to the engine, without any further adjustment whatever.

Standard System of Nozzle Calibration

With the adoption of the principle of gasoline flow calibration, and the decision that all nozzles must be calibrated on the "time instrument," new troubles were at first experienced, it being frequently found that nozzles calibrated in London failed to check up correctly when tested at Coventry or Birmingham. Many theories were put forward to account for these discrepancies, the most usual ones being that temperature and barometric pressure were affecting the accuracy. The author, while recognizing that temperature was possibly having some small effect, could not believe that this factor alone was responsible for the amazing differences sometimes found between a nozzle calibrated at the maker's works and the same nozzle when tested upon his master instrument at Coventry.

Causes for Test Differences

Investigations were made by taking nozzles which had been very carefully calibrated at Coventry and trying them in the instruments in use in London, and, strangely enough, the London figures were identical in every case with those obtained at Coventry. This was very puzzling, but finally the trouble was located, and found to be caused by three things, among which the factors of temperature or barometric pressure were *not* evident.

The first and most important cause of the differences was that the calibrating instruments used by makers did not have interconnected stopwatches, an ordinary 30-minute recorder, constantly working, being hung between two instruments, and doing duty for both. It was found that in order to save time the operators did not always start gasoline flow when the hand passed zero on the watch dial, but at the point which the hand happened to be passing when the nozzle was in position ready for calibrating, and as the operators naturally talked with each other while waiting for the minute to pass, it was very likely that in many cases calibration commenced at, say, 10 seconds past zero, and continued for perhaps 50 seconds, or perhaps 70 seconds, the operator, in the meantime, having forgotten just where she began.

The second cause of difference was that the particular nozzles in question, being of the diffuser type, had a cap screw, which, during the calibrating process, was left loose in order to facilitate its removal by the fingers when it was necessary to ream the orifice to size. When this cap was finally screwed hard home it then occupied a different position, and was closer to the nozzle orifice than it had been during calibrating, and this was found to vary the flow when again tested in the instrument by some 8 to 10 per cent.

The third cause of difference was that the cap screw mentioned was, after final assembly, locked by soldering, and it would seem that either the soldering fluid used or the heat had some considerable influence on the nozzle orifice, this being proved by the fact that nozzles calibrated immediately before and after soldering showed marked differences in discharge.

Three Master Instruments Provided

To settle disputes as to the accuracy of calibration figures, three master instruments were provided, which it was claimed were absolutely accurate and foolproof. These were designed by a London automobile engineer, the principle being that the opening and closing of the gasoline valve was automatically accomplished at an interval of exactly one minute. The energy was provided by a falling weight, and the time controlled by a quarter-seconds pendulum. Unfortunately, although the design was undoubtedly very ingenious, it did not work properly, and after much heartbreaking work it was finally decided to discard the automatic gear and to substitute an interconnected valve and stopwatch.

Shortly after the completion of these instruments, in consequence of the enormous increase in the number of nozzles being manufactured, it was considered necessary that an instrument should be produced in which the time element could be eliminated, and to this end a number of gasoline flowmeters were placed on order. After much labor and experimental work an instrument was produced which proved thoroughly satisfactory in every respect, and with the exception of certain alterations in details of design which have been rendered necessary by the ever increasing sizes of jets required, has remained unaltered in principle until the present day.

Toward the end of 1916 a serious fault was discovered in the standards which had been used for the calibration of the Mark I flowmeters, it being found that the effective head in the master time instrument was varying considerably with the size of nozzle being calibrated; this was due to the control valve being of insufficient size, which caused considerable restriction in the gasoline flow during calibration of the master nozzles. This defect had but very little effect when the maximum size required was in the order of 350 c.c. per minute, but with the advent of nozzles passing 700 to 800 c.c. per minute, required for the more powerful engines then coming into use, it became necessary to alter the master instrument, and to supersede Mark I calibration by Mark II.

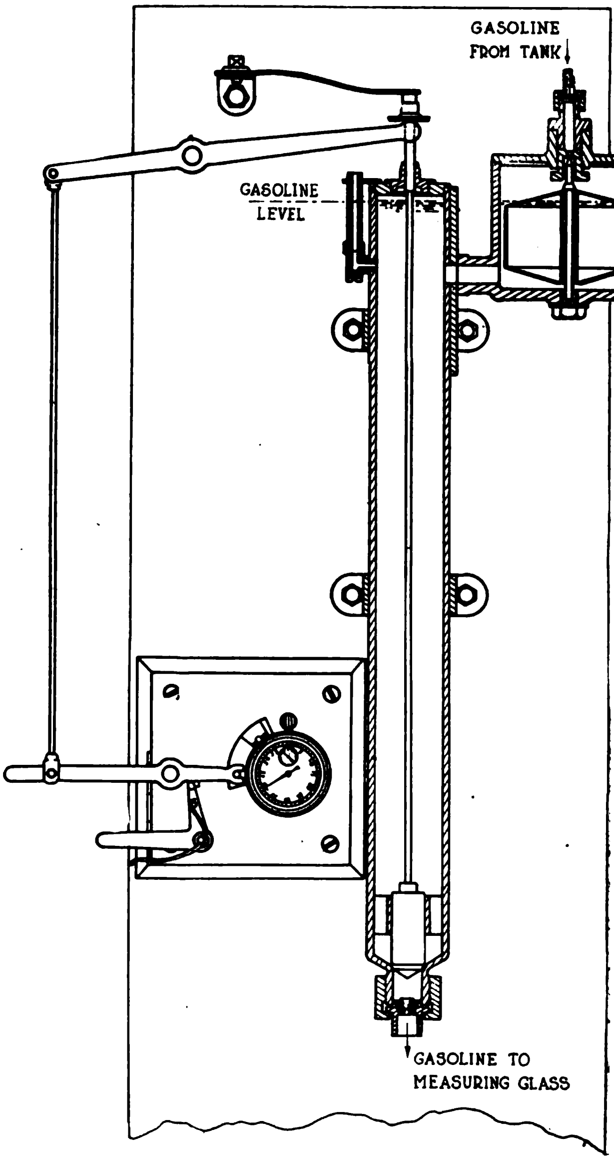

Fig. 2—Sectional view of master time flowmeter

Having arrived at the finally perfected and standardized Mark II instruments, a brief description of their construction and method of working will be given and, since the root principle has never changed, this will cover the whole range of instruments previously described.

Fig. 2 is a sectional arrangement of the master time instrument. It consists of a vertical tube A, fitted at the lower end with a control valve B, and with an adapter to receive the master nozzles shown in position at C; a constant level of gasoline 50 centimeters above the nozzle orifice is maintained by the float feed mechanism D.

The valve B is normally closed by the spring E, and is opened when required by the lever F, which is interconnected with the stopwatch lever G. The stopwatch lever when placed in the "on" position is retained "on" by the trigger H.

Gasoline is supplied to the float chamber from a tank above the instrument, and after passing through the nozzle is collected in the bottom tank, being returned to the upper tank for further use by means of an air pump.

Calibration of Master Nozzles

The method of calibration of the "master" nozzles is as follows:

Accurately made nozzles having all edges carefully rounded and with a length of "stricture" not less than three or more than five diameters of the actual orifice, are inserted in the adapter. The lever is pressed into the "on" position and gasoline is allowed to run for a minute or so to get rid of any air which may be present below the valve.

The trigger H is then released, thus closing the valve. The stopwatch is now set to zero and a graduated measure being placed under the nozzle, the control lever is again pressed into the "on" position, and gasoline is allowed to flow through the nozzle into the measure for one, two, three or five minutes, according to the size of the nozzle to be calibrated. It will be seen that the actual time during which gasoline is flowing is recorded by the stopwatch, and that should the operater fail to close the valve exactly on the minute intervals it is a simple matter to divide the actual time registered into the quantity of gasoline in the measure, and so obtain the exact quantity passed per minute. Fig. 3 shows a purely diagrammatic arrangement of the "flowmeter" type of instrument; this will be dealt with in the last section of this paper.

The principle upon which this instrument works may best be described as follows: A and B are vertical tubes connected at their lower ends by the venturi passage C. Tube A is coupled to a float feed mechanism which maintains within it a practically constant level of gasoline whatever may be the quantity passing away through the venturi C. Tube B is provided with an outlet at D controlled by a stopcock. It will be evident that when the stopcock is closed gasoline in tube B will reach the same level as in tube A, but if the stopcock is opened, the level in tube A will remain constant or practically so, but the level in tube B will fall to some point at which it will remain stationary, the amount of the fall depending upon the quantity of gasoline flowing from the stopcock, providing of course that this quantity is within the range of any particular instrument.

The range of difference in the height of the gasoline in the tubes is controlled by the discharge, under the constant head, through the venturi orifice, which in the instrument takes the form of an accurately made and carefully calibrated nozzle.

Formula for Scale of Flowmeter

The formula for calculating the scale graduations when the instrument is used as a measuring flowmeter is

$$Qa = C\sqrt{2\,gh}$$

or

$$h = \frac{Qa^2}{C^2\,2\,g}$$

Where Qa = Actual cubical discharge from the delivery side of the instrument.

h = The difference in height between the constant head on the supply side of the instrument and the reduced head on the discharge side.

C = The coefficient of discharge of the venturi orifice, which varies with the area of the orifice *and with variations of the detail design of each type of instrument*; therefore it is, of course, essential that the value of "C" be carefully determined experimentally in every case.

The Mark II nozzle calibrating flowmeter has two progressive scales which are calibrated, not in unit volume passed by the nozzle being tested, but to correspond with the amount passed by the corresponding master nozzle when this is tested in the master time instrument under a constant head of 50 cm.

How Instrument Is Used

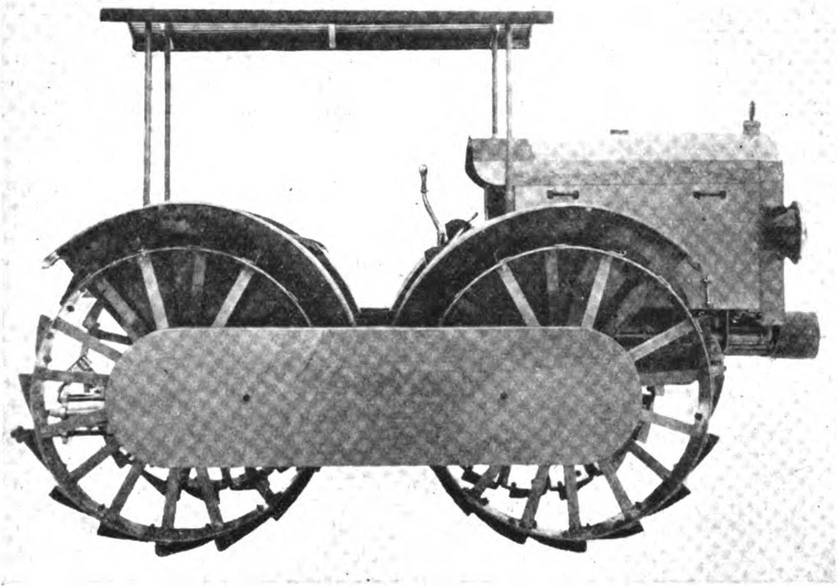
When using the instrument, the nozzle to be calibrated is inserted in a special adapter, under the scale upon which its desired size is found. The gasoline cock at the base of the gage tube is opened, and after the air trapped in the adapter has been released by means of the valve provided for this purpose, the level of the gasoline in the gage tube will drop and remain stationary at a figure upon the scale which denotes the size of the nozzle which is being tested, and it will be evident that this provides a method of nozzle calibration into which the personal equation of the operator cannot enter, since there is no measurement of time or of quantity required. It is desired to emphasize particularly the fact that the numbers given upon the scales indicate the quantity of gasoline which the corresponding master nozzles would pass under the constant head of 50 cm., but as the head actually acting upon the nozzle in this instrument varies with the size of the nozzle being tested, the actual quantity of gasoline passing through the nozzle will not be the quantity which is indicated upon the scale.

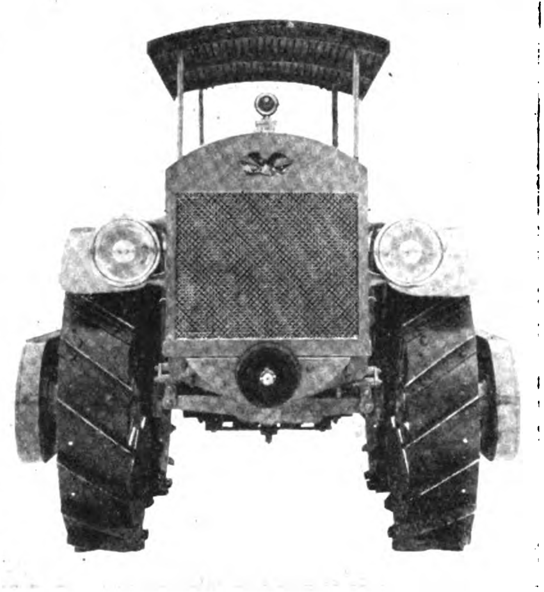
Types of Gasoline Flowmeters

When official acceptance tests of aero engines were first instituted, and in fact until some appreciable production had been reached, the usual method of obtaining the fuel consumption was to commence the test with a measured quantity of gasoline in the tank, and, having run the engine for the period required by the testing schedule, to empty out and measure the amount of fuel remaining in the tank. This had very grave disadvantages, in that serious inaccuracies were possible owing to carelessness upon the part of the workman in filling and emptying the tank; the author has, in fact, at the conclusion of a test frequently seen a measure being so held that gasoline was running directly on to the floor, the holder in the meantime being busily engaged in discussing some point of great interest with a fellow worker! There was also a very grave risk of fire, but the most serious disadvantage was that during the actual running time there was no indication of any fluctuation of changes which might be taking place in the carbureter action. Also, it was not possible to see the result of any change or adjustment made in the carbureter without running the engine for some considerable period. Upon the successful conclusion of their work in connection with the Mark II nozzle calibrating flowmeter, Messrs. Brown & Barlow were requested to submit a flowmeter to meet the following conditions:

(1) Accuracy within plus or minus 2 per cent.
(2) Steady indication at any rate of flow within its range.
(3) Maximum possible range of scale to be obtained.
(4) Length of connections between the instrument and the engine not to affect accuracy.

This instrument was produced and was tested, being connected in series with the ordinary tank containing a measured quantity of gasoline. Readings were taken at intervals of fifteen minutes, and these were averaged at the conclusion of the test and compared with the reading obtained by actual measurement. The results of a considerable number of tests carried out in this manner showed the flowmeter to be accurate within less than $\pm$ 1 per cent; the only condition which was not quite fulfilled was that of steady indication under all conditions. This trouble was completely eliminated and a steady indication was obtained. A large number of the instruments were placed on order, being classified as engine test bench flowmeter Mark III.





Heinze Tractor Has Novel Drive

Equipped with Ball-Bearing, Kerosene-Burning Engine of New Design—Drives Through Enclosed Side Chains to All Four Wheels and Steers Like Creeper Tractor

THE four-wheel drive idea has had adherents in the automotive field from the early days of the passenger car and truck. In the passenger car field it never got beyond the experimental stage, because the advantages which it affords over the two-wheel drive do not warrant its complication and extra weight. In truck practice the four-wheel drive has conquered quite a field in recent years, mainly in connection with ordnance transport. It would seem that if this drive had any justification at all, it would have it in tractor work, because a tractor must develop driving effort sufficient not only to propel its own weight over loose soil but to haul a plow or other implement as well. Driving lugs of suitable design no doubt serve greatly to increase the limiting traction, but these add to the weight to be moved, and they also consume power. It is obvious that even with four-wheel drive it would not be possible to use smooth steel rim driving wheels, but the lugs could be made much smaller. That four-wheel-driven tractors have not reached the production stage before this is probably due to the fact that the complication and heavy manufacturing costs ordinarily associated with four-wheel drives has deterred manufacturers from adopting it. The chain tractor is in a way equivalent to a four-wheel-drive machine, as it makes the whole weight of the tractor available for traction purposes.

A four-wheel-drive tractor of unusually simple construction, known as the Heinze, has been placed on the market by the Traction Engine Co., Boyne City, Mich. The complication of the ordinary four-wheel drive is owing to the fact that the front axle has to be arranged for both driving and steering. That is, assuming the Ackerman steering is to be used, the front-wheel spindles have to be pivoted on the axle, and universal joints have to be used for transmitting the power from the axle to the wheels. Mr. Heinze has avoided this difficulty by steering on the same principle as a creeper-type tractor is steered; that is, applying brakes to the two inner wheels, so that driving power will be applied to the two outer wheels only. All the wheels, therefore, remain at all times parallel with each other, and there is no difficulty in driving the two wheels on each side through a single chain. Some people might question the effectiveness of this method of steering, but the manufacturers claim that the machine turns at right angles and in a radius less than its length.

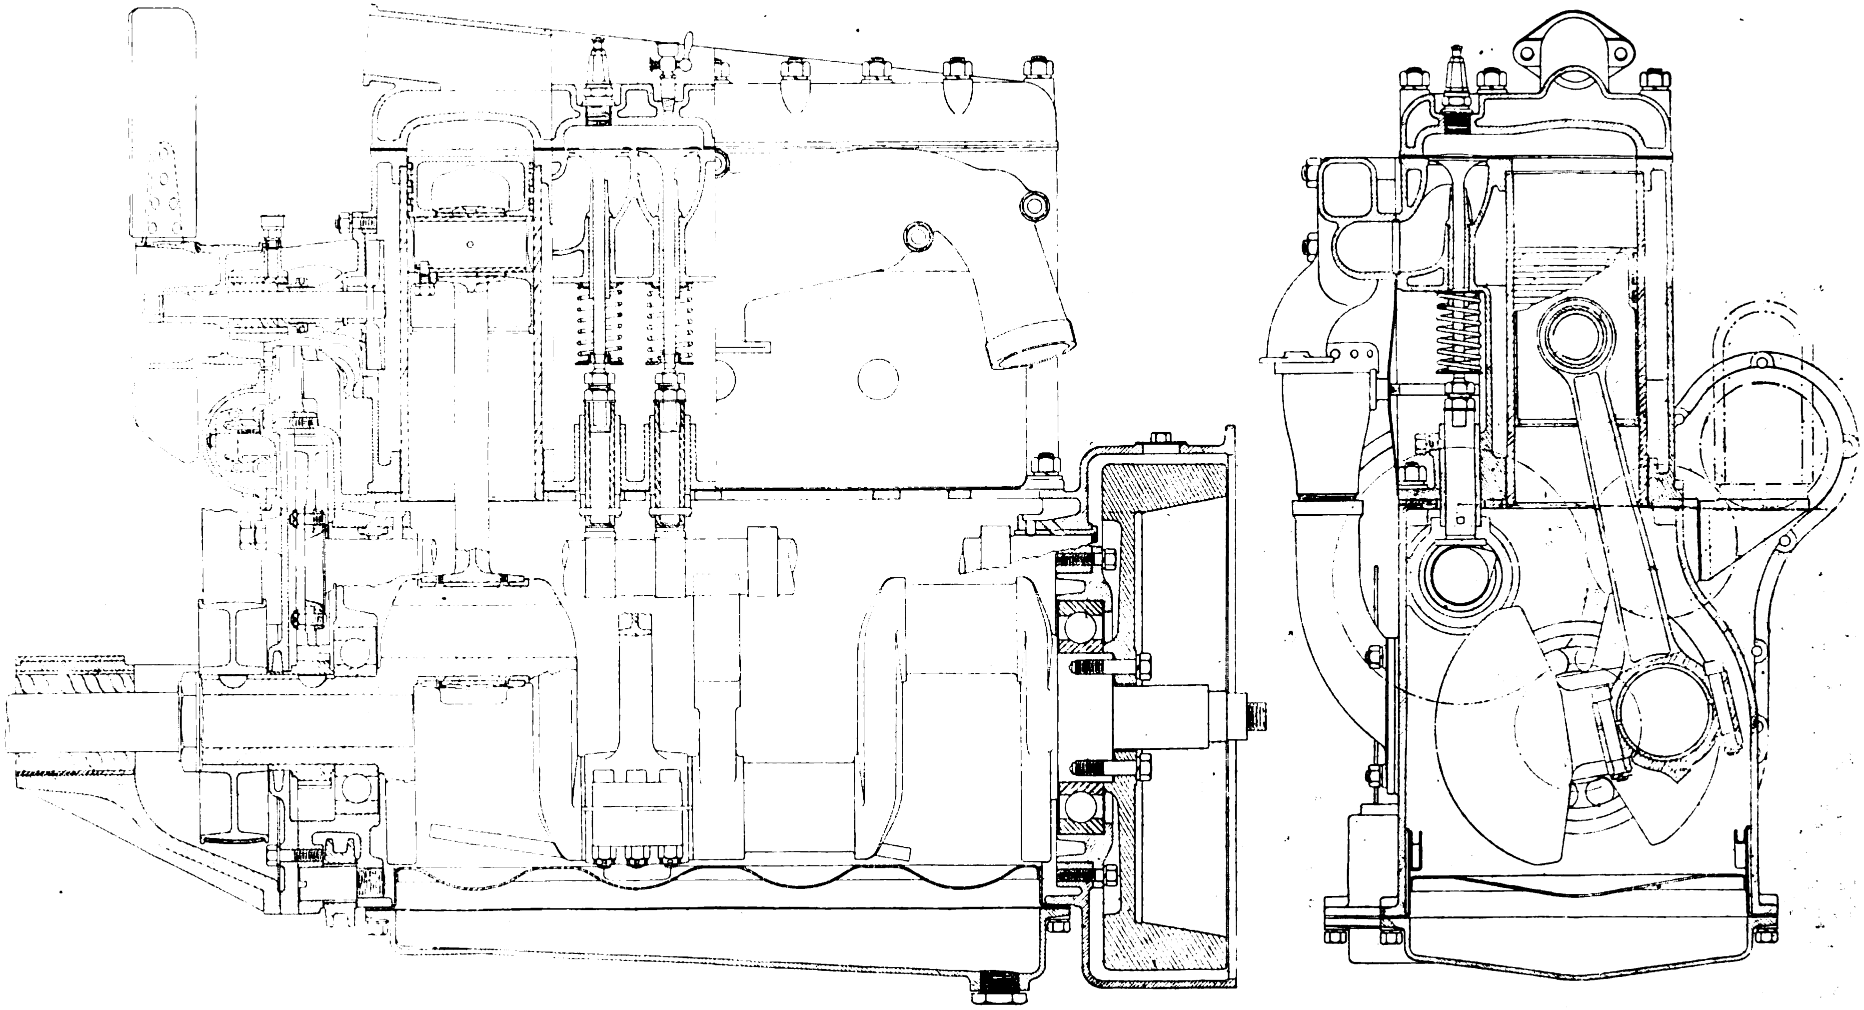
We will first describe the engine, which is of Mr. Heinze's own design, and manufactured by the Traction Engine Co. In this connection it is worth noting that John A. Heinze was formerly general manager of the Northway Motor Mfg. Co., of Detroit, and consequently has had extensive experience in the design and manufacture of gasoline engines. His new engine is of the four-cylinder block type, with detachable heads. Among its most notable features are the use of case-hardened steel liners for the cylinders and two ball bearings on the crankshaft, together with balance weights on it. The engine is of 4¼-in. bore by 6-in. stroke, and is of low compression, in view of the possible use of kerosene as fuel. The cylinders are of the L-head type, all of the valves being located on the left-hand side. The valves have a clear diameter of 2 in. and a lift of ⅜ in. It is notable that there is a large filler between the valve head and valve stems. Mushroom-type cam followers are used, and the camshaft is forged integral with its cams, in the usual way. This camshaft is supported in two bearings only, and consequently is of unusually large diameter, 2 in.

Crankshaft of Unusually Heavy Dimensions

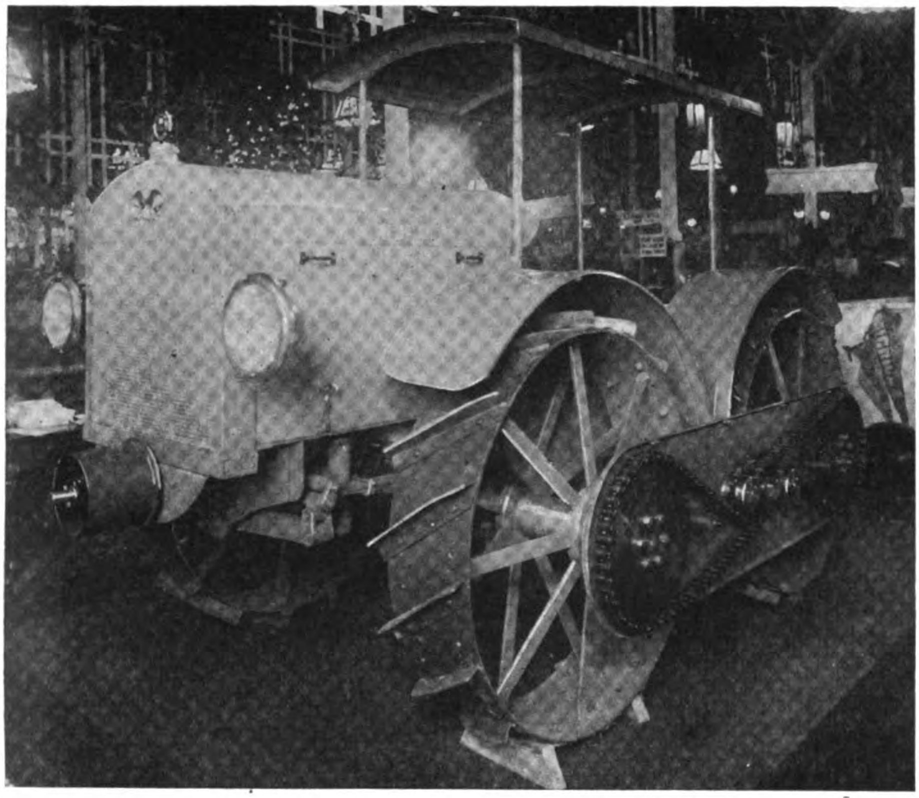
The crankshaft is a drop forging of unusually heavy dimensions. It has crankpin bearings measuring 3 x 3¾ in. The crankshaft is carried in two annular ball bearings, a No. 315 medium series at the front end, having a rated load capacity of 4400 lb., and a No. 222 light series at the rear end, having a rated load capacity of 5000 lb. Balance weights are forged integral with the two short arms of the crankshaft, and there is also a heavy balance weight between the central double crank pins. In order to reduce the weight of the crankshaft, both the crankpins and the main bearings are bored out. The crankcase is cast in a single piece, open at the bottom.

The pistons, which are of cast iron, are provided with three sets of two rings at the upper end. The hollow piston pin, which is of unusually large diameter, is fastened in the piston bosses, and the bronze-bushed connecting rod rocks upon it. Cast integral with the crankcase is a bell housing for the flywheel. The piston-pin bearings measure 1⅞ in. in diameter by 2⅜ in. in length, and the connecting rod has a length

Heinze 30-40 Hp. Engine for Farm Tractors



Among the noteworthy features of this engine are the very rugged crankshaft and camshaft, the crankshaft ball bearings, hardened steel cylinder liners, crankshaft counterweights, pump and fan on same shaft and high-speed centrifugal governor



A view of the Heinze at the Tractor Show, with chain cover removed

of 13 in. There is also plenty of bearing surface on the pistons, which are 6 in. in length. The timing gears are made of steel and cast iron, for the pinion and gear respectively, and have helical teeth.

Ordinarily the tractor is fitted for operation on kerosene, and a kerosene capacity of 20 gal. and a gasoline capacity of 2 gal. are provided. A combination inlet and exhaust manifold is used, so that some of the heat of the exhaust can be utilized in vaporizing the kerosene. Ignition is by a high-tension magneto. Lubrication is by splash, the oil being circulated by pumps. There is an oil capacity of 3 gal. in the crankcase.

The cooling water is circulated by means of a centrifugal pump, which comprises only an impeller, the ordinary pump housing being dispensed with and the impeller located directly within the engine jacket. Both the pump and the fan are mounted on the same shaft and are driven by a 2-in. flat belt. The fan has 3 blades, and is 20 in. in diameter. A centrifugal governor is mounted on the foreward end of the magneto driving shaft.

Transmission

A large Raybestos-faced cone clutch is located within the flywheel. The transmission is of the sliding-gear selective type, and gives three forward speeds in addition to the reverse. All transmission shafts run on large annular ball bearings and operate in oil. From the main shaft of the transmission the power is transmitted to the differential shaft through a worm and worm wheel. This differential shaft, which is located transversely on the frame, midway between the front and rear axles, extends all the way across the tractor, and carries a sprocket pinion on each end. From these sprocket pinions the transmission is by two chains to the four driving wheels, an idler sprocket being used on each chain for taking up the slack.

The roller chain is enclosed in a steel housing and operates in oil. The small driving sprockets and the chain idler sprockets are carbonized, heat treated and ground; the large sprockets are made of steel, and have machine-cut teeth. Every bearing of the drive is provided with a pressure grease cup.

The belt pulley, which is located at the forward end of the tractor, is of 8 in. diameter by 8 in. face and is crowned. It operates at a speed of 1200 r.p.m., and sets directly upon a forward extension of the engine shaft. A substantial bracket bolted to the forward end of the engine crankcase supports this shaft extension on a Hyatt roller bearing.

As will be observed from the longitudinal sectional view of the engine, the latter is arranged for three-point support upon the main frame. At the forward end the frame is supported on the axle by means of half-elliptic side springs, and in order to insure greater flexibility the forward ends of these springs are not shackled directly to the frame but to a cross-bar, which is swiveled to a cross-member of the frame in front. All four driving wheels are of the same diameter, 42 in., and also have the same width, 10 in. With lugs attached, the width is 12 in. The overall length of the tractor is 125 in. and the overall width 72 in. Without canopy the height is 62 in., and with canopy, 86 in.

A laterally adjustable drawbar is provided. The road clearance is 14 in. The tractor is equipped with fenders, and it also has front and rear lights for night plowing.

The engine rating is 30-40 hp. at 1200 r.p.m., and the tractor weight is 4000 lb. At a speed of 1 mile per hour on hard, soddy soil, the tractor will deliver a pull of 6000 lb., while at a speed of 3 miles per hour on loose sandy soil it will develop from 3000 to 3600 lb. drawbar pull. It is sold as a 3-4 plain tractor.

Use of Coal Gas as Motor Fuel in France

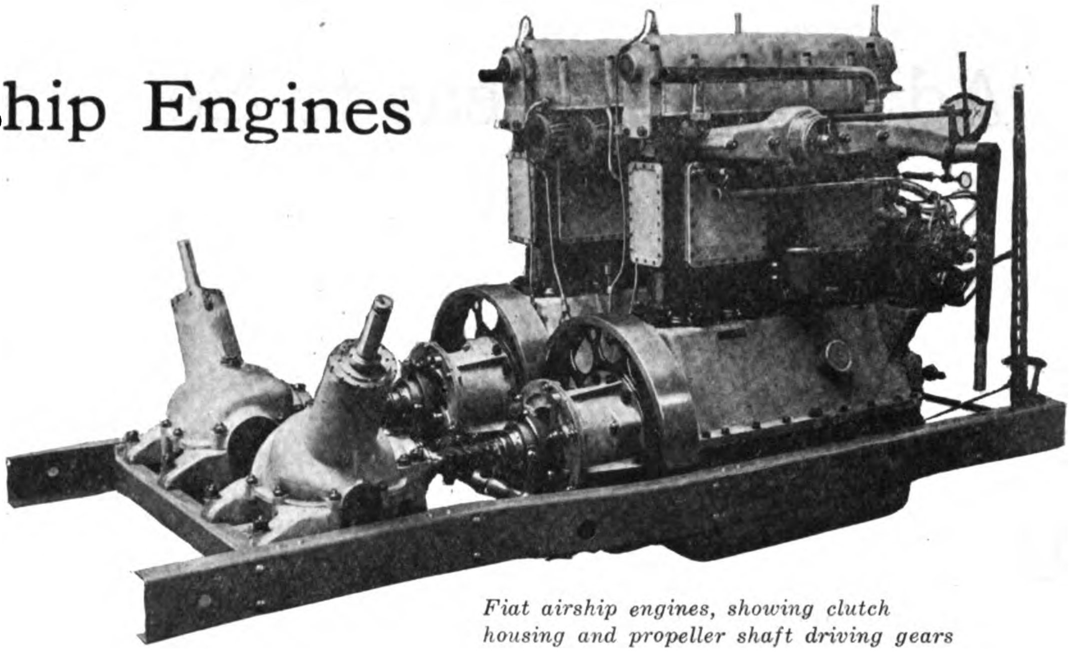
BEFORE the war the scarcity and expense of volatile liquid combustibles was causing anxiety in France, Italy and Germany, and the war has greatly increased it. One of the means of obviating the difficulty is to employ illuminating gas, of which 1.650 cu. m. at 4700 calories is equivalent to 1 litre of gasoline of a specific gravity of 0.730. The annual consumption of gasoline and of benzol produced from coal before the war had attained 350,000 tons, of which 130,000 tons was benzol. Now the consumption is about double. In the gas-works of France about 30,000 tons of benzol are being produced yearly, and when the coking plants in the Nord area are reinstated the output should reach 50,000 tons. French benzol only represents some 7 per cent of the total requirements of France. The consumption of internal combustion engines varies from 2500 to 3000 calories per hour, and assuming an average of 2750 calories this is represented by 0.25 kg. of benzol.

Gas from which the benzol has been extracted has a thermal value of about 4700 calories per cubic metre at atmospheric pressure and about 0.3 kg. by weight. The present price of benzol is more than 1 franc per litre outside Paris, and gas 0.3 franc per cubic metre not compressed, so that the cost of benzol per mile may be taken as double that of gas.

In a recent article in *Le Genie Civil*, the author, after quoting the practical results obtained in England, describes what has been done in France. L. Neu in 1913 took out a patent for an installation which permitted the use of either gasoline or gas upon a given automobile. Experiments have recently been made with a Renault of 8 to 9-hp. car, a Renault limousine of 12-14 hp., and a Renault 3-ton truck. Each was fitted up with an arrangement by which gasoline or gas or a mixture of both could be used, and the tests proved that about 1.7 cu. m. of gas of a thermal value of 4700 calories was equal to 1 litre of gasoline. They also showed that gas could be satisfactorily employed in all three types of vehicles without any serious structural alteration.

Fiat Airship Engines

Mounted in Pairs in a Channel Section Frame—Starting Gear Mounted on Camshaft Drive Shaft



Fiat airship engines, showing clutch housing and propeller shaft driving gears

DURING the war Italy made a very extended use of airships for coastal patrol work and for the detection of submarines in the Adriatic and the Mediterranean. The great majority of these airships were equipped with Fiat engines. The size and type of engine varied with the airship, but a very popular installation was a twin group composed of two four-cylinder engines placed side by side, and as close together as possible, in a channel section frame. These engines have a bore and stroke of 110 by 190 mm., the cylinders being a block casting, with enclosed valves in the head and large aluminum water jacket plates on the sides and the ends. The overhead camshaft is operated by means of an enclosed vertical shaft and bevel gearing, and advantage is taken of this shaft to mount the starting gear by means of a lever and bevel gearing. The carbureter is placed on the outside of each engine, while the exhaust is on the inside.

At the base of the vertical shaft the water pump and the high-tension magneto are driven by means of bevel gearing. These two organs are opposed, so that the magneto distributors and contact breakers are on the outside in each case. Each engine is fitted with a light flywheel and a coil clutch, the control of which is by means of a lever at the forward end of the engine. From the clutch shaft the propeller shaft is driven by means of bevel gearing, this shaft having an inclination of about 45 deg. from the vertical.

It will be seen from an inspection of the photographs that the two engines are not exact duplicates, but are right and left respectively, the design evidently making for accessibility.

Advertising Ideas to Sell American Goods Abroad

Successful Men Agree There Is No Single Rule, but That a Distinctive Plan, Made to Fit the Article and the People to Be Reached, Must Be Worked Out for Each Country

By Allen Sinsheimer

DOES advertising for export trade pay? What mediums and forms of advertisement are most profitable? These questions were asked at the group session on advertising at the recent Foreign Trade Convention and were answered by advertising authorities and business men with practical foreign experience.

Nearly every method of advertising used successfully for the development of domestic business, it was said, has been found appropriate and profitable in various foreign countries, but no blanket form of advertising can be applied to all foreign countries. Each country must be studied as to its customs, social, industrial and financial conditions, and the advertising must be as carefully adapted to each country as domestic advertising is adapted to the various articles of trade.

It was generally agreed that newspapers, American export magazines, local weekly and monthly publications, billboards, street car, railroad station, poster and handbill advertising are each successful in certain foreign countries. The application of any of these media, however, must follow a thorough practical and psychological analysis.

It is not possible, for example, to write an advertisement in the English language and translate it into Spanish with profitable results. No advertisement, the speakers asserted, can be written in English and translated into a foreign tongue without losing its selling force and appeal. Expressive American phrases are unknown abroad and the translation becomes meaningless. The advertisements should be written in the language of the country for which they are intended, by a native of that country or a writer familiar with both the country and its language.

Foreign Advertising Must Be Done By Manufacturers

Foreign advertising must be done directly by the manufacturers, and not through local dealers, who are likely to use the wrong media or carelessly expend the appropriations in wasted efforts. Expenditure of advertising funds directly by the manufacturer insures a consistent nation-wide campaign in place of spasmodic local efforts.

No two countries can be sold on the same publicity plan and this even applies to nations as closely situated as Brazil and Argentina. Many manufacturers have plunged into their foreign advertising campaigns without first making a careful survey of the fields and inquiring into the mental characteristics and material conditions of the people, their customs, peculiarities and systems. A proper survey of each nation includes:

The population.
The buying power per capita.
Literacy and illiteracy.
Importance of women and the family.
Native industries.
Superstitions.
Average wages paid.
Agricultural conditions.
Highway, general topographical and climatic conditions.
Local and national taxes.
Native customs and peculiarities.
Retail distribution.

Investigation of Local Conditions Essential

Stories are told of American manufacturers who have wasted huge sums by not first investigating these factors; of the implement maker who advertised lawn mowers in China where they have no lawns; of the syrup advertised for pancakes in Peru where they know nothing about pancakes; of the chewing gum advertised as a cure for smoking in Argentina, where the Argentinian would give up his all for a life-long supply of cigarettes. Similarly it is futile for an automotive manufacturer to advertise automobiles in a country where the highways are too narrow to allow their use.

The buying capacity per capita is an important consideration in apportioning the foreign advertising appropriations. Such appropriations will be most successful in those countries, other conditions being equal, where the buying power per capita is the greatest as a result of a more universal prosperity.

Literacy and illiteracy are fundamentals in the preparation of foreign advertising copy. In the Latin American countries particularly, where 50 per cent of the people are unable to read or write, advertising should consist chiefly of illustrations and simple phrases, with the prices conspicuous and plain. In Cuba, for example, the people are of an easy-going, pleasure-loving nature, not over fond of thinking and are attracted more by what they see than by what they read. The appeal to sight by means of large billboards or electrical displays, calling attention to the gorgeous upholstery and brilliant finish of the automobile, is most successful, and the best Cuban advertisements in magazines are those in which the illustrations have local color, drawn by either a native artist or some one who knows the country and the people, with the trade-mark or brand name well played up. Price is important. The text should be brief and to the point.

The importance of the women in the home is a consideration that should influence passenger car advertisements. Woman's situation varies in different countries and while in some she can be an important influence in the sale of a car, she may have little or no influence in

others. Latin American women have but little influence on the purchases for the families and are chiefly proud of their domestic qualities. They are likely to be more proud of a washing machine than of an automobile.

Superstitions, also, are important and particularly so in the preparation of advertising copy which contains illustrations of the commodity and its trade-mark. The Chinese, for example, have numerous superstitions, consider certain symbols unlucky and cannot be persuaded to accept commodities bearing what they consider ill-omens even as a gift. Similarly, there are many subjects which they consider lucky and they also exhibit a marked weakness for certain colors, buying those commodities regarded as lucky or which have the favorite colors even though not needing them. Certain countries give birds, animals or symbols high heraldic station and the selection of the trade-mark should be made with consideration of this if the mark is for that country only.

Retail distribution enters into advertising when it is of a local nature because of the customs of various countries. In the Far East it is customary to use the "compradore," a sort of go-between who acts between your representative in the field and the native. In China the compradore acts as the Chinese manager and credit man, usually furnishing cash guarantees and meeting obligations which have not been paid by the customer. As a rule the compradore is an influential, well acquainted individual and local advertisements referring to him are the most profitable.

MANUFACTURERS who have successfully built a foreign trade in American merchandise agree:

Reputable American export journals are indispensable as advertising mediums in building up a dealer clientele. These journals are regarded by dealers as catalogues of what is new in the industry represented.

The mediums for reaching the consumer are as numerous abroad as in this country, but usually they need not all be used in one country. Billboards, posters and handbills, if well illustrated, reach the Chinese. Newspapers and posters are profitable mediums in Argentina. Colored pictures appeal best to the Cubans. Newspapers, if well selected, are useful in Brazil, Peru, Australia and other countries.

Advertising media demand as much analysis as the preparation of the copy itself in each country. The use of cut-outs, calendars, post cards, souvenirs and attractive illustrated trade literature for distribution by local dealers has been found an excellent plan in some countries, magazines, daily newspapers, posters and handbills in others, while still others respond more readily to billboards and railroad station and street car displays. Particular stress was laid by all the speakers on the value of American export trade publications, which, it was said, are looked upon, especially in South America, as monthly or weekly catalogues of the American products of the industry represented, and in the case of reputable papers are highly regarded.

The use of local newspapers in Argentina, Brazil, Peru, Australia, South Africa and the Far East has been found profitable, according to Howard G. Winne of the Johnson Overseas Co. Billboards, posters and handbills are successful in China. Posters have been profitable in Argentina. The railroads of Uruguay and Argentina are owned by British companies who have followed the British system of display advertisements in the railroad stations, and the natives have come to understand them and respond favorably to them. The street cars of Brazil are owned by American capitalists who inaugurated the American system of advertising in the cars and Brazilians have become accustomed to this form of advertising.

The newspapers of each country must be studied separately to determine the selection. This applies also to the local and national weekly and monthly publications. Many of the publications reach only certain class trade, as, for example, there are more than 500 newspapers published in Buenos Aires, 100 of which reach specific foreign colonies only. Sunday papers in foreign countries, unlike the American Sunday papers, are worthless and useless. The various large advertising agencies of this country with foreign trade departments have made a study of most of the papers and are in position to advise the manufacturers. Although there are many newspapers and magazines, the good ones are so obvious by contrast that the selection of media is relatively an easy matter. In many countries the newspapers fill the place of both magazine and paper and are read both in the home and at business.

Manufacturers will find, it was stated by all the speakers, that those American advertising agencies which have established foreign advertising departments have anticipated the development of export trade and have made research in many countries and have complete data for analysis of the different markets. They have on hand information showing the appropriations necessary to conduct a successful campaign, the kind and style of copy that is most effective and the most effective media for placing it before the public. The American Association of Advertising Agencies is compiling a report of sources of available information on foreign advertising and foreign business which manufacturers planning a foreign campaign will find beneficial.

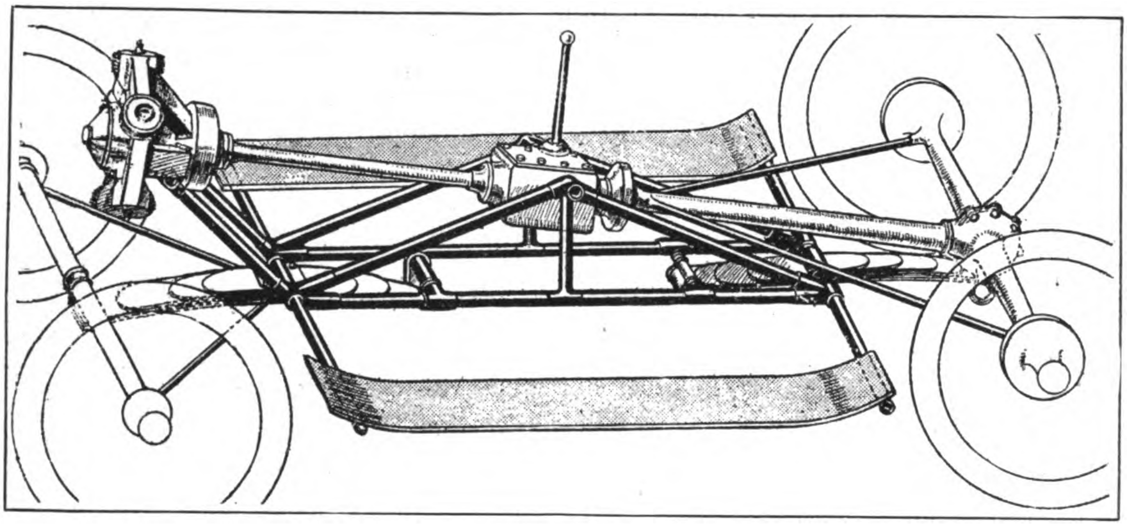
That advertising abroad is successful was shown by examples of selling, ranging from 25 cent cans of talcum powder to highly priced machinery, which have been sold through export publications, foreign and local newspapers, weeklies and other media described above.

If a manufacturer or his advertising manager, after ascertaining that there is a market for his product, will secure a thorough knowledge of this market, applying the same conservative, well considered and developed selling and advertising methods that he applies to the cultivation of his home trade, he can undoubtedly secure even more profitable results abroad for a given expenditure than he can at home. W. G. Hildebrant, of the Gotham Advertising Agency, cited a number of firms, some of which appropriated less than $5,000 for the first year, that are successfully selling manufacturing tools, soaps, toilet lotions and various other commodities at a wide range of prices, as a result of judicious advertising.

But it must be remembered, agreed all the speakers, that there is no cut and dried plan, no rule of thumb method which can be successfully applied to all products or to all markets. Each market must be analyzed.

Radial Engine Revived in England

Cycle-Car Type of Machine with Five-Cylinder, Air-Cooled 10-Hp. Engine to Be Marketed by Enfield-Allday Co.—Cloverleaf, Three-Passenger Body Fitted



Sketch of the general assembly of the radial engined car, showing the peculiar springing arrangement, also the tubular frame and engine bearers. This sketch is purely diagrammatic

TWO models of cars are provided for in the post-war program of the Enfield-Allday Co. of Birmingham. One is a six-cylinder four-pasenger touring car, while the other is a small 10-hp. radial engined car. The engine of the latter consists of five air-cooled cylinders bolted to a stationary crankcase in which is a single-throw, built-up crankshaft.

The crankcase is bolted to the frame. The crankshaft carries, at its rear end, a small flywheel, which is in reality a Sirocco fan, and is used to draw a current of air over the cooling flanges of the cylinders. The cubic capacity is 1208 c.c. (74 cu. in.), while the bore and stroke are 62 x 80 mm. (2.44 x 3.15 in.). The maximum horsepower is 20.5 at 2500 r.p.m.

The engine itself is placed in the orthodox position in front of the car under a hood of circular shape.

In place of the radiator there is a perforated screen which is hinged at the top, and can be lifted up for inspection purposes. By a rather clever arrangement it is possible to disconnect the engine and swivel it, so that any desired cylinder can be brought round to the top. (Care should be taken not to confuse the radial with the rotary engine, the latter being the type mostly used in airplanes and having a set of cylinders revolving round a stationary crankshaft. The radial is another type.)

Each cylinder forms a separate casting, with a series of circular radiating fins extending from near the base up to the combustion chamber. Arranged centrally at the top of the cylinder proper, but of less diameter, is the combustion chamber with two series of valve ports round it. The valves, which are operated from overhead, consist of two concentric sleeves, the exhaust resting on a bevel seat in the cylinder extension, similar to a poppet valve seat, while the inlet has a seat formed on the inner circumference of the exhaust valve and normally covers a series of ports cut in the latter, through which, when the inlet is raised, the exhaust gases pass.

The valve mechanism imparts to the valve sleeves (as they may be termed) a slight reciprocating movement lifting them from and returning them to their seats, as is the case with poppet valves.

As regards their operation, no camshaft is used, but the large wheel of the two-to-one gear is provided with a side flange, on which the cams are formed, and a simple actuating mechanism is connected up by rods—mere wires under tension—with the overhead levers. The latter are acted upon by the valve springs, which are situated externally, and not affected by the temperature of the cylinder walls.

Advantages Claimed

The following points are claimed for this system of cylinder and valve construction: Absolute uniformity of cooling; an extremely large valve opening area in proportion to cylinder capacity, with a very small valve lift; the explosion terminal pressure does not resist the opening of the exhaust valve, thus enabling the valve-operating gear to be of very light construction; both valves can be removed with the cylinder head by taking off four easily accessible nuts; and, lastly, no leakage of oil can occur from the valve mechanism.

The pistons are of the slipper type, made of aluminum alloy, with four rings. The crankshaft carries a master connecting rod running on a plain bearing on the crank and supporting on its big end four articulated connecting rods for the remaining four cylinders. The big end has no bolts, being formed in one piece, and threaded onto the crank pin when the built-up shaft is assembled.

Lubrication is by the dry-sump method. A double pump is used, one section of which forces oil through the hollow crankshaft, while the other sucks up all the surplus oil from the base of the crank chamber and returns it to the oil reservoir at the side of the machine. An advantage claimed for this system is that the lubricant is kept cool and clean.

The magneto and carbureter are of orthodox design, although the latter embodies an extra air inlet which is controlled by hand.

The transmission is by means of a single-plate clutch connected by a long hollow shaft to the three-speed gearbox, having the lever mounted centrally upon it. From here the drive is taken through an enclosed propeller shaft to helical bevel gearing in the back axle.

Central Cantilever Springs Used

The system of springing is quite novel, and departs entirely from the usual design. The springs themselves are but two in number, both cantilevers, and are arranged *centrally* in the frame, one at the front and one at the rear. Outriggers project from the frame at each side to support the body, while at the front end of the propeller shaft casing is a flexible connection with the body to prevent undue side sway, which would otherwise occur in the absence of a spring or other support at each corner. Triangulated rods are provided, both in back and front, to keep the axles at right angles with the center line of the car.

The makers state that the object of this novel form of spring construction is to reduce vertical oscillation of the frame to a minimum. In addition it is claimed that the car will hold the road better and that an appreciable reduction of weight is secured.

The standard body supplied with the radial engined car is a three-seater of "cloverleaf" pattern. The top, which encloses all three seats, folds back into a special compartment out of sight. The body itself is built on aero construction lines. It closely approximates streamline form, with inswept sides and a bulbous back. To render accessible the gearbox and other details beneath the body the latter is pivoted or hinged at the rear end, so that it can be raised up several feet at the front end. The wheels are of the pressed-steel disk type, and are of unusually large diameter for a car of this size, being 810 x 90 mm.

The wheelbase is 8 ft. and the track is 4 ft.

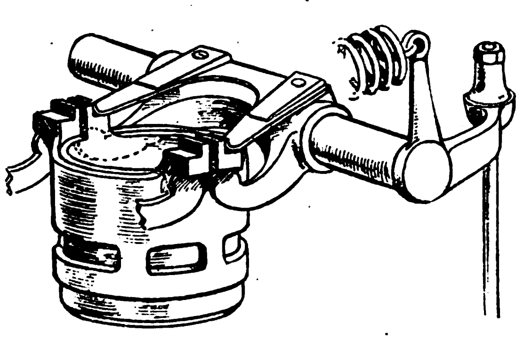
It may be pointed out that the aim has been to design a light attractive type of sporting car, providing exceptional speed with the comfort of running of much more costly vehicles. Reduction of weight should insure not only marked improvement in acceleration and hill-climbing, but also a reduction in running costs as regards both tires and fuel. As regards the latter, economy should be apparent, owing to the practical increase in cylinder temperatures obtained by the adoption of air cooling, and a design enabling these higher temperatures to be attained without distortion of the cylinders and valves.

The Six-Cylinder Model

The second type being built, already referred to, has an engine with six cylinders of more normal arrangement; that is to say, they are water-cooled, and are vertical and in line on the top of an aluminum crankcase. The same valve system is used as the one already described. Each cylinder is a plain tube, reduced in diameter around the valve and combustion chamber. To secure uniform thickness, and consequently that uniformity of cooling which prevents distortion, each cylinder is machined inside and out and has a narrow water space enclosed by a steel jacket through which the water is circulated by a special force pump. Provision is made for relative movement, due to unequal expansion, between the cylinder barrel and the jacket.

The bore and stroke are 70 x 110 mm. (2.75 x 4.33 in.), giving a piston displacement of 2500 c.c. (153 cu. in.) and delivering 21 hp. at 1250 r.p.m.

The remaining details are much the same as those of the radial engined car. Both cars are sold complete with electric lighting and starting sets—the 10-hp. car for $1.275 and the larger for $2,495.



Above—Sketch showing the method of operating the sleeve valves. The complete fork shown takes effect on the inner, or inlet valve, while the outer valve, the exhaust, is operated by a similar fork mounted the same way on a transverse spindle

Continental Plant Layout Facilitates Production

Engine Shipments Go Out on Same Tracks on Which Raw Parts Enter—True Progressive System Used

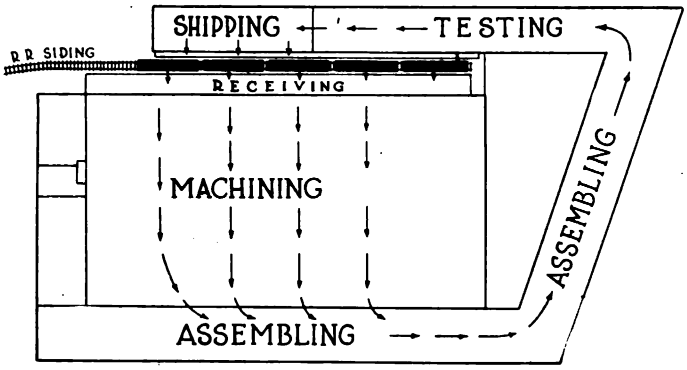
MATERIAL production at the Detroit factory of the Continental Motors Corp. moves around the four sides of a square. By this arrangement manufacture and assembly are carried out along strictly progressive lines without the necessity for the long, narrow buildings generally required for this purpose. In fact, the finished engines leave the shipping room, just across the freight siding, alongside of which is the receiving room from which the raw parts were originally started, and the same cars which came in with the raw material go out with finished engines. A very ingenious plant layout has permitted this result to be achieved.

If the operations in the manufacture and assembly of the 250 to 300 engines now daily passing through the plant were strung out in a line the building required would be extremely long and narrow and would necessitate long walks on the part of officials in reaching various parts of the plant. As it is, the plant dimensions are 560 by 760 ft., or 425,600 sq. ft. Through this plant there pass more than 100 tons of raw material per day, of which about 90 tons are transformed into finished engines. There are about 2,100 productive men employed in the manufacturing departments, these men working on 8-, 9- and 10-hr. shifts. Six different models are being manufactured, but there are about 75 sub-types.

The layout and arrangement of the plant can be understood from the map herewith, which makes plain how it is possible to take this practically square plant and yet have true progressive manufacturing and assembling methods. As will be seen from the map, the freight siding enters the rectangle and runs practically across it near one end. This divides the plant roughly into a process department and the testing and shipping work department.

Leaving the freight tracks on one side, the materials enter the receiving department, then the stock bins, pass across one side of the rectangle through the manufacturing departments until they strike the assembly department on one end; whereupon they pass around the other three sides of the rectangle, finally terminating at the shipping platform, where the finished engines are placed in the same cars which brought in the raw material.

The methodic handling of material commences even before the freight cars enter the receiving department. The cars are shunted around in the yard outside of the plant until those containing material which goes to the far end enter the building first, and the cars which contain material near the door enter last. Thus, as the cars come in on the track the materials are approximately in the place where they should be. Fig. 1 shows this track. In this illustration we are looking into the receiving department in the direction the cars enter. The unloading platform is subdivided from the receiving and inspection department by the white line running parallel with the track. Material which has been received must be kept within this line, and the area parallel with the track laid off by this line forms the receiving platform. The materials are inspected immediately upon receipt and placed on standard racks adapted to carrying them. All of these racks are raised from the floor on blocks of wood, so that it is possible to slip the low platforms of the industrial trucks beneath them, raise them from the floor and carry them to the stockroom. In Fig. 2 is shown one of these industrial trucks raising some cylinder blocks which have been inspected, these being taken to the stockroom by the receiving department truck.



Layout of the Continental engine plant, showing the compact, progressive system of manufacture. The rough parts are unloaded from one side of the freight cars and pass through the machine shops to the assembly chains, at the end of which the engine is tested, packed and shipped into the same freight cars from the opposite side

Receiving inspection is completed before the materials enter the bins. There are gages of all sorts to check over the material which is fabricated or semi-fabricated outside. Thus, the accuracy of the incoming parts is given a thorough check before they enter the raw stockroom, and for manufacture, all material and semi-fabricated parts are drawn from finished stock; thus the finished stockroom forms a division between the receiving department and manufacturing.

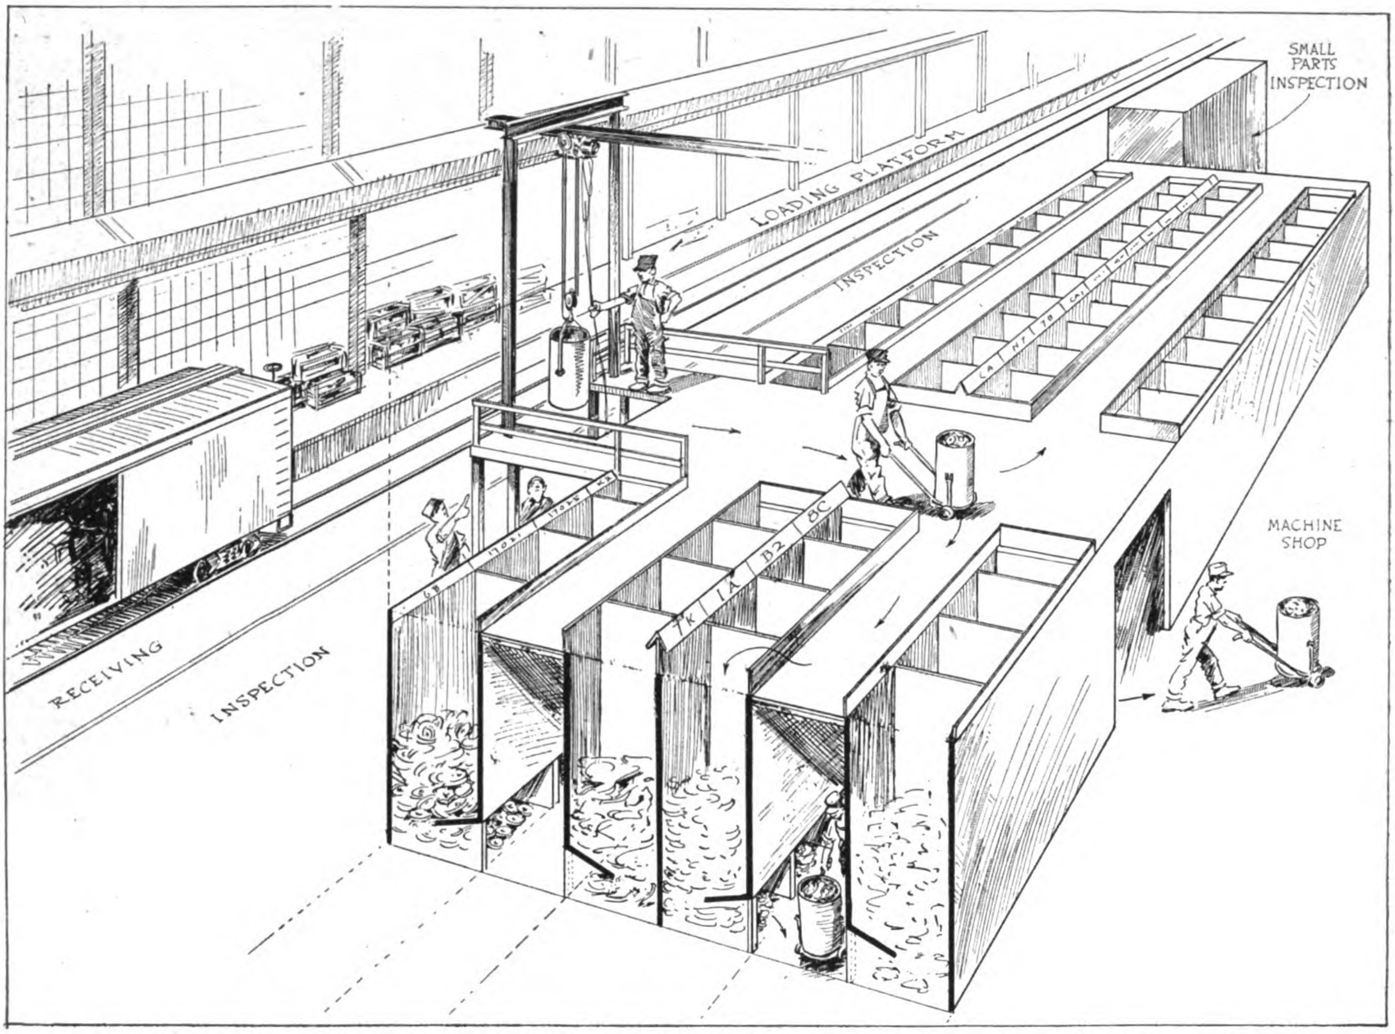
An interesting type of bin is used in the Continental raw stockroom. This is a hopper type for small parts such as timing gear blanks, etc., and is illustrated in Fig. 3. The material is used in approximately the same order in which it is put into the bin, the parts being drawn out at the bottom and put in at the top. In fact, they are loaded into the top of the bins, right from the receiving room, as will be noted by referring back to Fig. 1, where the open tops of some of these bins are shown along the left wall.

The raw material stockroom extends across one end of the manufacturing department and from this stockroom manufacture takes its start. The stockrooms are adjacent to the manufacturing departments which handle the parts contained in their particular bins, and the manufacture of these parts proceeds in parallel lines directly across the manufacturing department, terminating at the other side where there is a finished stockroom from which the parts are drawn for assembly.

In a few instances the passage across the plant would be too short to complete the manufacture of that part. In a case of this kind the parts double back and then, if necessary, back again. In the case of the crankcase and cylinder blocks, this is necessary, owing to the large number of operations on these parts and the amount of space required for the machines. Approximately, however, the lines of manufacture are parallel across the

Fig. 2—Type of electric truck now in use at the Continental factory

Fig. 3—Gravity-fed stock bins for small parts. These bins are filled from the loading gallery above



Section through the rough stock bins at the Continental plant, showing how the parts are hoisted from the receiving platform and sorted. They are withdrawn from underneath as required for the machine shop

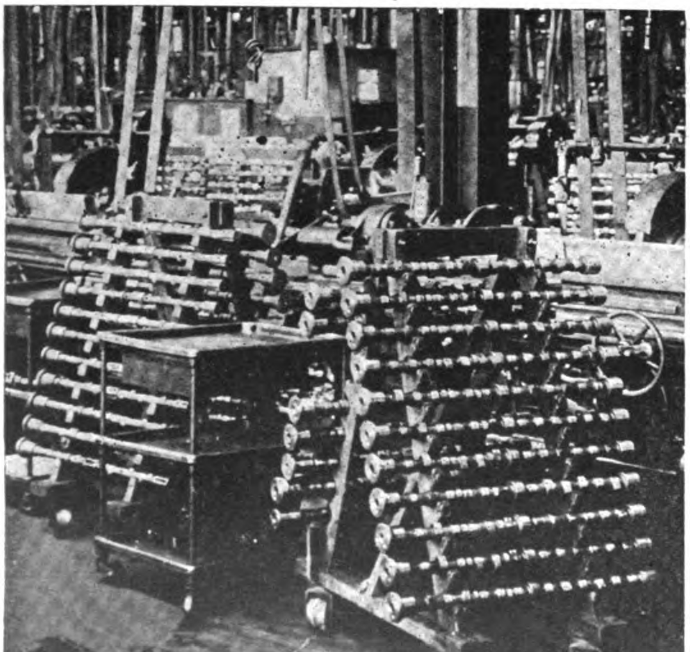


Fig. 4—Camshaft carrying racks in the finished grinding department of the camshaft floor

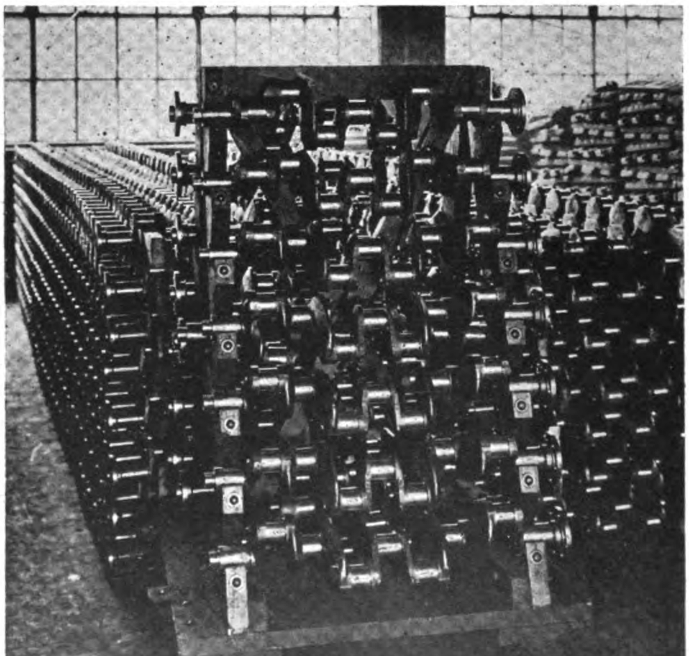

Fig. 5—Crankshafts in finished stock; also type of rack used for handling crankshafts in the grinding department

plant. One line will take flywheels; the next, crankshafts; the third, valves and tappets; the fourth, camshafts; the fifth, the flywheel covers; then there are two or three rows for the crankcases, cylinder blocks, sheet metal parts, manifolds, pistons, etc. These are the principal lines of manufacture and follow one another about in the order given, across the plant.

An effort is made to keep everything off the floor. Everyone who is familiar with engine manufacture remembers the piles of camshafts which used to lie upon the floor of an engine factory. A much neater way of handling this is by the use of racks. Fig. 4 shows a large number of these racks in the camshaft department. As may be noted, these racks are on wheels so that they can be pushed along from one machine to another, as desired. The racks handle twenty-four camshafts at a time in a neat and clean manner, and, being readily movable, a great amount of handling is eliminated by their use.

The type of rack used for handling crankshafts is shown in Fig. 5. This is a wheel type of rack, used in the departments where the crankshafts have to be moved about. It is capable of handling fourteen crankshafts and is of particular value in the grinding department and on the assembly floor where the shafts are moved along with the engines.

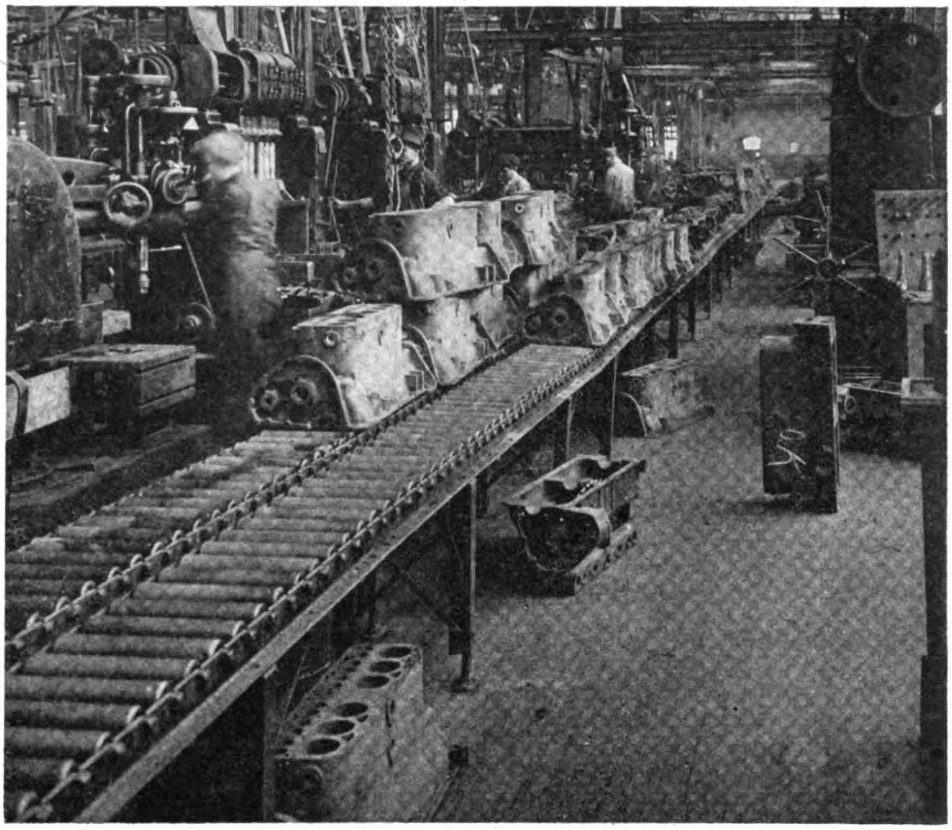

Fig. 6—One floor of the Continental cylinder boring department, showing type of carriers for handling cylinders. This railroad extends from the first operation in the cylinder department through the cylinder grinding department and connects with the conveyors in the assembly

Another type of crankshaft rack, without wheels, is used in storing the crankshafts, as the racks are very compact and result in very little waste space when they are used. Handling of the material through the manufacturing department is primarily accomplished by roller

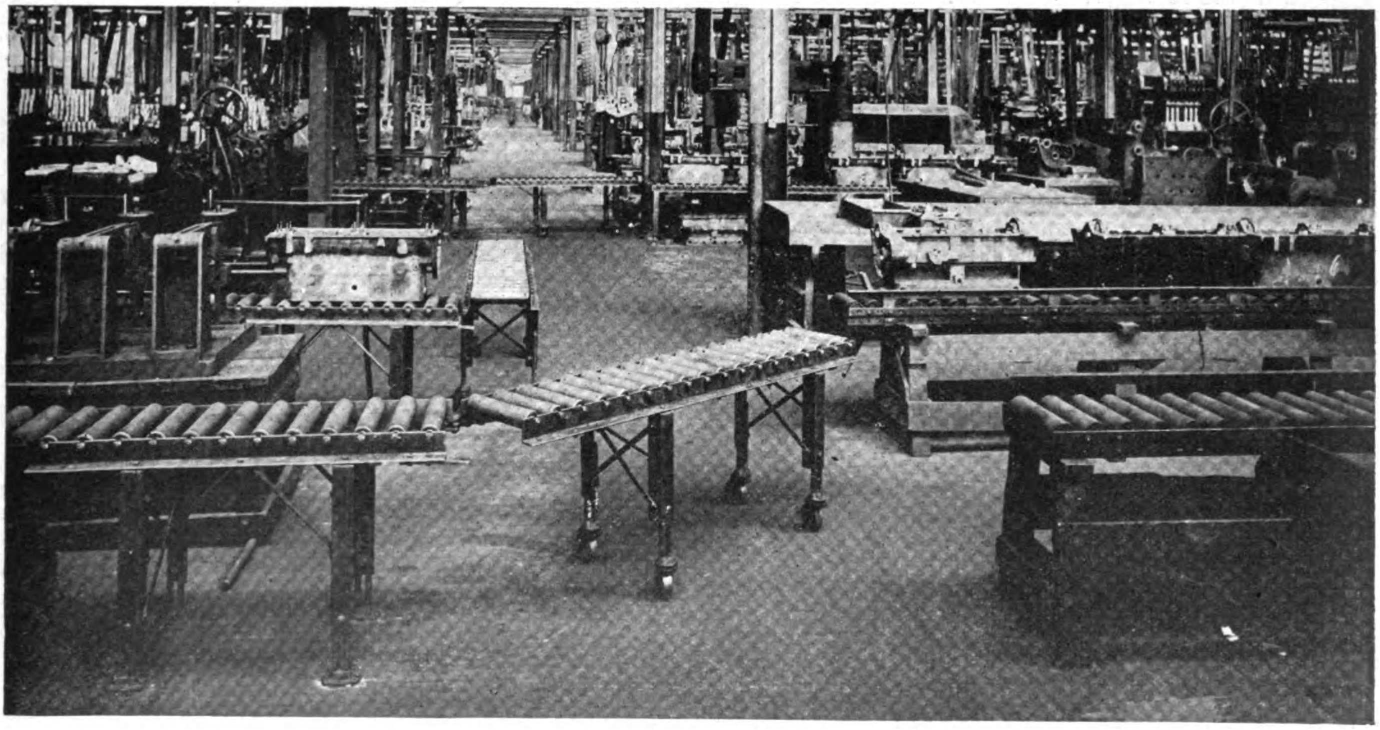

Fig. 7—General view of part of Continental machine shop, showing method of installing ball-bearing carriers where they cross the traffic aisles

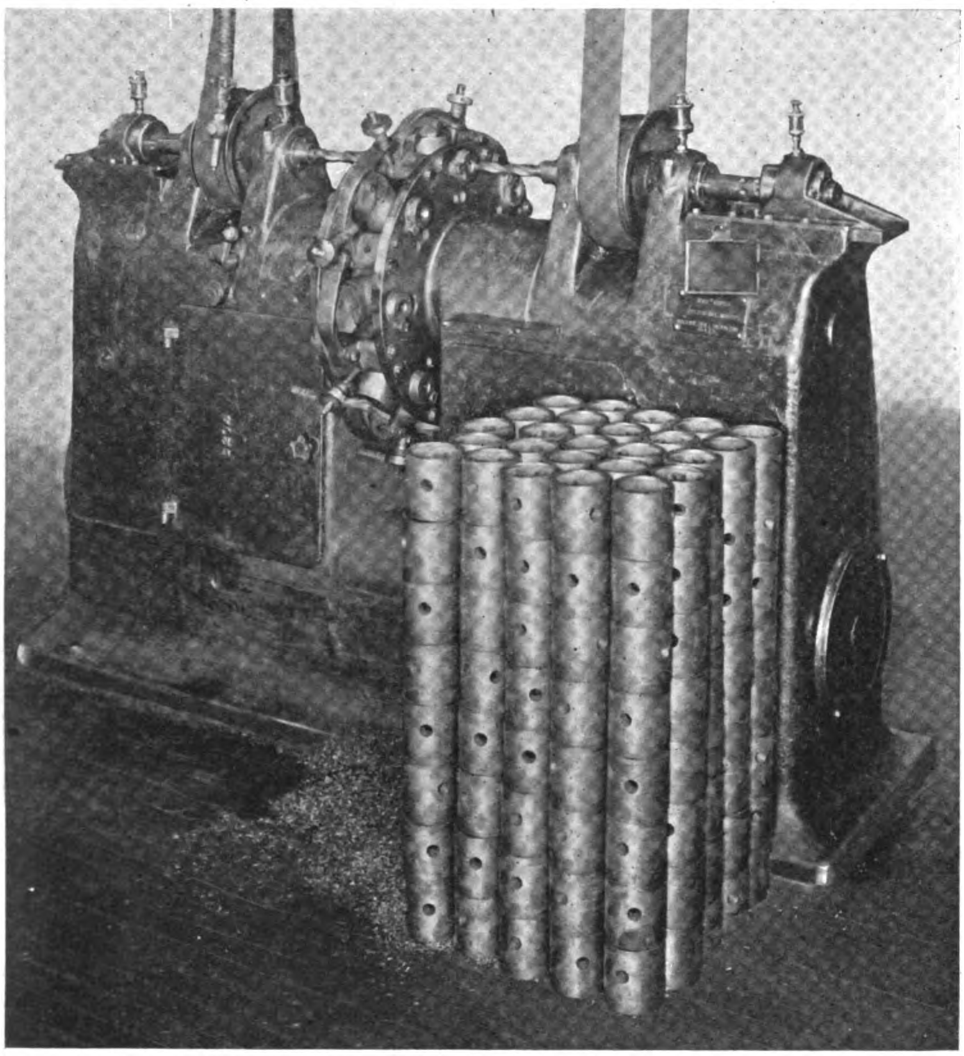

Fig. 9—Machine which drills the holes in the piston for the piston pin. These holes are drilled from each side. Machine takes eight pistons at one time

conveyors. For assembly, special types of racks, which will be explained later, are employed. The roller conveyor, however, is used to transport the materials from machine to machine, and, as will be shown in Fig. 7, a double row of these is used to handle the heavy parts upon which there are a great many operations requiring two or more rows of machines across the plant.

Fig. 6 shows the cylinder blocks working along the roller conveyor, and in this photograph they have just reached the boring department. In making use of these roller conveyors across the plant, naturally some provision has to be made for crossing the aisles, and this is done by ball bearing carriers or switch-overs, illustrated in Fig. 7. These can be swung across the aisle when necessary and are readily pushed out of the way should passage be required. They are hinged at one corner so that they are always in alignment when swung into place.

The railroad or roller conveyor system for the cylinder blocks extends from the first operation in the cylinder department through all of the boring, drilling, reaming, tapping and other cutting machine departments, to the cylinder grinding departments and finally connects with the conveyors in the assembly.

The progress along this railroad is really the determining factor in the timing of manufacture through the plant; in fact, the milling operations at the beginning of the cylinder and crankcase manufacture are the vital elements in determining the plant timing.

It is not the purpose in this article to describe, step by step, the manufacturing processes employed in making the Continental engines, as these follow conventional lines, except for a few important departures which may be pointed out as we make a brief trip through the manufacturing department before we see how the assembly works its way around to practically the point at which the engine started.

The piston department is of great interest because of the large number and variety of pistons sent through the plant every day. One of the interesting machines in this department is that for drilling the holes in the piston for the piston pin. As will be noted, the pistons are held in the circular fixture which is a part of the machine. The drills enter from both sides, simultaneously, and the machine is capable of handling sixteen of these pistons per hour. This gives a semi-automatic machine and is capable of handling the pistons for any engine, as the holder can accommodate pistons of various sizes and is easily set up. This machine is illustrated in Fig. 9. *(To be continued)*

A New Swiss Motor Plow

A COMBINED tractor and plow has been developed by the Swiss Locomotive & Machine Co. of Winterthur. The plow and motor are mounted upon the same frame, which is carried upon three wheels. The motor is an internal-combustion engine of 30 hp., suitable for light or heavy gasoline. A two-cylinder heavy-oil motor cannot be employed, owing to the scarcity of heavy oil. This motor drives the two front wheels through a shaft with differential gearing in a dustproof casing, and ball bearings are provided.

The wheels have flat strakes fixed to the rims and angle-iron lugs are bolted on for plowing. All three wheels travel on the unplowed land. The plow is a three-bottom type and the framework has a certain amount of free motion independent of the motor portion. The whole apparatus can be managed by one man. When the plow is disconnected the remainder can be used as a tractor or as a stationary engine.

The chief dimensions are as follows: Driving wheels, 63 in. diameter; third wheel, 29.5 in. diameter. Total length with plow attached, 18 ft.; breadth, 6.9 ft.; height, 6.2 ft.; weight, 6150 lb.; speed forward, either 1.7 or 3.75 m.p.h.; weight of the three-bottom plow alone, 1320 lb.; width of three furrows, 42 to 46 in. and depth of furrow, 6 in. to 14 in. The engine consumes 0.66 lb. of gasoline per horsepower hour and runs at 800 r.p.m.

Improved Oil-Pressure Regulation in Liberty Engine

Early Engines Tended to Overoil at Low Speeds

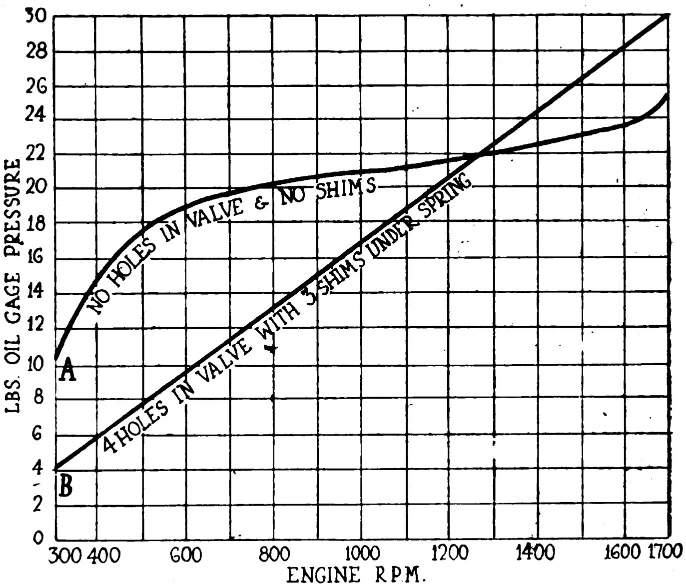
THE original design of undrilled release valve on the Liberty engine pressure oil system gave pressure results at the various engine speeds as indicated by curve A on the accompanying chart.

This shows that the oil distribution was not properly related to the engine requirements at various speeds and a tendency to overoil at the lower speeds resulted, this tendency being most marked when making a long glide with the engine turning at 800 to 900 r.p.m. and the throttle fully closed. To correct this in the simplest manner possible, four positive bypass or leak holes (No. 52 drill) were drilled through the relief valve, resulting in lower initial pressures and a curve building up more nearly in step with the engine speed. All engines are now adjusted to give 28-32 lb. pressure at approximately 1700 r.p.m., the oil at a temperature of 65 deg. C. (212 deg. Fahr.) (Liberty Aero Oil Specification No. 3501).

This adjustment is obtained by means of shims 1/32 in. thick, inserted under the relief valve spring, and from two to four of these shims will be necessary, depending on the fit of the engine bearings, the pump gear clearances, etc. Shims may be readily manufactured at the fields, or common iron washers can be secured to answer the purpose.

The later engines show 28 to 32 lb. pressure at 1650 to 1750 r.p.m. (see curve B) when thoroughly heated up by ½ hr. of 9/10 to full power flying at an altitude of 3000 to 6000 ft. with water temperature approximately 75 deg. to 85 deg. C. (165 deg. to 180 deg. Fahr.) and with average air temperatures. Ordinarily three shims will accomplish this, and, of course, the pressure will be much higher when starting out with the engine and oil only moderately warm. It may also drop somewhat lower after 2 or 3 hr. in the air, particularly if the supply gets a bit low.

If oil of higher viscosity than Standard Specification No. 3501 should be used, a smaller number of shims is required, but in no case should less than one shim be inserted. Because of the shape and location of the oil tank in the DH-4 the oil often gets up around 90 deg. C. (195 deg. Fahr.) and it will average 65 deg. C. (150 deg. Fahr.). Consequently, it is never safe to allow the supply to get lower than 6 qt., and 8 is better as a minimum. When the supply gets lower than 6 qt., it passes through the engine bearings so many times per minute that it has not sufficient time to cool and soon breaks down, resulting in damaged or burnt-out bearings.



Oil pressure chart with and without shims under valve spring

Naturally a high-viscosity oil stands up better under such punishment.

Where unusual difficulty is encountered in getting the pressure to hold up, one of the four leak holes can be plugged with a drop of solder, but this is very bad practice, since it raises the pressure too much at the gliding speeds and the plugs are almost sure to foul on a long glide with closed throttle.

On engines equipped with the hydraulic CC type of synchronizer, the cock in the line between the pressure gage line and the synchronizer must be closed when testing oil pressures. Ordinarily this cock should be opened only at intervals for a few minutes, to give the synchronizer an extra oiling, but if the guns are used excessively it may be necessary to leave the cock open when flying. In this case the pump should first be adjusted and tested as outlined above and then one leak hole plugged with solder. This is necessary because the oil in the cock is practically equivalent to one of the regular holes, and four is the maximum number that should be used. Adjustment, however, should not be made with cock open and the leak hole plugged, because the gage does not register accurately when the pressure line is being "bled" by the synchronizer feed through the open cock. Engines fitted with the Nelson synchronizer or mechanical interrupter do not have a feed of this kind, and the gage registers correctly under practically all conditions.

In cold weather difficulty will be experienced with lubrication unless full precautions are taken. Use hot oil and boiling water. Do not exceed 800 r.p.m. as a steady warm-up, although the motor can be accelerated and slowed down to throw oil up into the cylinders. Cold

Strong Tendency for Co-operation in Labor Ranks

Willingness of a Majority of Actual Workers to Join with Employers in Adjusting Differences and Adapting New Conditions Has Been Overshadowed by the Sensational Programs of the Radicals, Who Wish Only to Rule

By Harry Tipper

THE growth in the adoption of systems involving the combined action of management and employees upon the questions of wages, hours and other matters which affect the working conditions, has attracted less attention than the actions of the radicals in labor and the existence of excessive demands which have their basis in the program of the irreconcilables, which was mentioned in last week's article. The attention which has been accorded to the unrest among the working bodies, and tho success of the radicals among labor organizations in some localities in forcing strikes, is due in part to the change in the point of view brought about by the war and the general expectation that conditions will not go back to the pre-war organization entirely.

The vociferous demands of the radicals in labor organizations have affected the outlook of the conservative labor leaders and the affiliated organizations of labor, to this extent, that they must recognize the unrest that exists in their own ranks and the necessity for some action, where this action is not entirely destructive of the affiliated labor organization ideals. Because of these conditions there has been a general tendency to confuse the demands, which have originated with the radicals within the labor ranks, with the demands of the affiliated organizations as such. This has led many manufacturers to condemn the viewpoint of all labor in its organized endeavors, without studying the question and without realizing the conditions which exist within the labor organizations, and the fact that the leaders themselves are obliged to compromise between the conservative opinions and the radical demands within their own ranks.

Real Objects of Organization

As these matters are chronicled in the daily press and in the general publications, no distinction has been made between the objects of organizations such as the I. W. W. and the objects of the regular affiliated unions as such. It is true that in several localities within the last six months the radical part of labor opinion has been able to assume command of the local situation and to start general strikes, against the desires of the more conservative of the labor body, practically assuming control of all unions by taking advantage of the existing machinery of labor organization and diverting it to their purpose. These movements are not countenanced by the older and wiser heads in the occupational labor unions, and they can be discounted to some extent as a natural result of present conditions, particularly the restlessness and demand for expression which were not visible before the war period.

On the other hand, the growth of combined bodies within the individual industrial organization itself, by which manufacturer and employee can have equal representation in the matter of wages, hours and other working conditions, indicates a development of constructive thought and study upon the problem of human relations in industry that is far more important in its suggestions of future growth.

The whole program of the radical within the labor organization is destructive. It aims at sweeping away the present system without any constructive idea of how it is to be replaced. The more conservative and moderate members of the labor organizations and their leaders understand very thoroughly the futility of such a program, and the final result of any attempt to progress materially in that direction.

A somewhat similar condition exists among manufacturers and employers and those having control of industrial operations. The more moderate, studious and farsighted of such organizations are developing plans whereby the manufacturer and employee shall determine the conditions of work in co-operation with each other on the theory that it is the right of the employee, and the duty of the employer, to give the worker some adequate voice in the government of his own working conditions. There is a considerable section of opinion in financial and manufacturing circles, however, which still believes that it is possible to continue industrial organization on the same basis as it has been developed for years, and who see no value in any suggestions for change or even in any discussion of the subject.

Too Much Attention for Radicals

Unfortunately, the minority of radicals in the labor organization succeed in securing a majority of the attention, and similarly the views of those employers who see no value in anything but the maintenance of the old system of supply and demand are widely heralded, while the desire of the majority of manufacturers and those in control of industry to deal fairly with the matter on any adequate basis receives little or no attention. It is this feature of the situation which is somewhat disturbing. Despite general strikes in some localities, and the statements of some of the radical labor leaders, there is evidence that the extreme opinion in labor circles is the opinion of a very small proportion of the total body of labor only. Comparatively few of those in control of industry will be willing to subscribe to the platform erected by the few who have received public attention because of the strength of their denunciations and the positiveness of their position. For the most part, however, the moderates on both sides are inarticulate, and they are receiving their impressions as to the general opinion of the other side from the radicals, who are bound to develop their own program, and that only.

In the last two months in not less than 20 or 30 cases,

manufacturers have quoted to me the extreme statements of one of the irreconcilables among labor leaders and insisted that this represented the general platform of labor as it is organized in this country. Similarly a number of labor leaders have quoted the extreme statements of some of the manufacturers and have stated that nothing could be expected from bodies who held such opinions, intimating that this was the general platform upon which the manufacturer stood.

It is perhaps only the student who will patiently gather together all the records in the case. For him the situation presents elements of constructive progress that cannot be overlooked. When the manufacturer states that there is no satisfying the worker and that nothing will avert a strike, the mind reverts to the 12 or 14 cases recently recorded where the workers in an individual plant have refused to join the general strike in which their occupation was concerned. Everyone who has any interest in industry, whether from the employers' or the employees' point of view, has read of the serious strikes in the textile industry at Paterson, N. J., and of the demands of the workers, but few people know that in one large plant not a worker left his work during the strike.

Decisions of Employees Themselves

In New England, when the skilled mechanics were demanding more pay and less hours, a plant referred the question of a reduction in the number of working hours to its employees, the reduction being necessitated by the conditions of the business, and an agreement was reached to reduce the week to 4 days without any trouble.

When the labor leader insists that there is no hope of securing a fair deal from the manufacturer and that labor must force its program through in order to control the situation, the mind is immediately confronted with the records of at least 20 plants where the workers have not only refused to strike but have entirely altered their viewpoint upon wages and hours, and have testified to their faith in the square dealing of the concern by their decision on almost every possible point which might arise.

The fact that these things are occurring and are demonstrating in these individual plants the workings of cooperation between employer and employee in the settlement of working conditions is the most encouraging sign in connection with industrial organization and production development in the near future.

Ordinarily our perspective is so warped by the attention to the differences, by the desire for the sensational and the fact that things are ordinarily understood to be interesting only as they record a fight, that we are in danger of assuming a condition of affairs which does not exist, and basing our opinion and actions upon those assumptions, whereas in reality they should be based upon a different conception entirely. The future solution of this question cannot be helped by the opinions and actions of the vociferous irreconcilables on either side, who can see no possibility of value in any other program than the one which they have laid out.

Solutions for Present Unrest

Of the two, the labor irreconcilables are the most dangerous, because they would substitute for present organization, which is at least of some value, experimental organization, the value of which has not been demonstrated and which on its face does not appear to have any elements of constructive possibility. The man who is in control of industry, however, and who refuses to discuss, study or consider the question of the worker's aspirations, his point of view and his necessities is in almost as bad a position, because he cannot offer anything which will solve the present unrest, and the history of the matter shows that warfare has not decreased as industry has grown.

The work which has been done by many organizations, some of which are the largest and most important in their fields, in meeting this question of industrial relations in a reasonable and moderate way is encouraging because it indicates the practical possibility of such steps. It has gone far enough to show the practical working out of such methods, and it has been in motion sufficiently long to prove that no serious calamity necessarily accompanies the change.

The minority radicals on both sides can be reinforced into a majority only if they are allowed to govern the opinion and the action of the moderates. This is due to a general misconception as to their place and standing. If the moderates among the manufacturers are willing to adopt practical means of adjustment, will take the time and effort to study the opinion, the point of view of the workers, whether in the shops or the offices of their organization—if they will examine the changes which have been made by important and stable concerns in their endeavor to deal with the question and act upon the result of their thorough investigations, there is good reason for hope that industrial organization in this country will take a long step in advance and provide a stability which has not been secured in any other country, and which cannot be secured under present conditions.

Training Helps Workers to Help Themselves

THREE-FOURTHS of the industrial workers in America are handicapped by lack of proper training in their respective tasks, according to the U. S. Training Service of the Department of Labor. The work of the Service is to increase the efficiency of this "insufficient three-fourths," rather than to stimulate the output of the one-fourth already producing at a satisfactory rate, says a bulletin, "Some Advantages of Industrial Training," now being distributed by this branch of the government.

Bringing about a big increase in output of the average plant, the government contends is wholly within the possibilities, if the following steps are taken: (1) A careful analytical survey of the operations in the plant to ascertain where existing methods can be improved; (2) the formulation of a definite program of training, either in a separate department or "on the floor" in direct conjunction with production; (3) the instruction of those workers who are most in need of it and (4) the upgrading of those in the next higher strata. A training department helps workers to help themselves.

Another question of keen interest to the workingman and the employer alike, taken up in this booklet, is the effect of training on labor turnover. It points out that the turnover for the country at large is at least 250 per cent., placing an annual burden of $1,250,000,000 on our manufacturing industries. Basing his claim on the experience of several score of plants where training has been installed, the author maintains that such instruction in a factory causes a big reduction in turnover. The trained employees can more readily find suitable work and are more easily retained in a plant. Training contributes to a better spirit among employees and develops better teamwork with the employers.

Congressional Action Needed for Commercial Aviation

THE need of prompt Congressional action in developing regulations for commercial aviation in the United States was emphasized by the announcement of the Army Air Service to the effect that it will establish air routes between, and landing fields in, certain cities.

Military authorities cannot visualize commercial requirements. In the selection of cities and the construction of fields they will naturally be guided chiefly by military requirements. Sites will be selected more because they conform to the military plans for defense rather than because they fit into a logical scheme of development for commercial aviation.

It has been announced that the fields are to be constructed through co-operation with the municipalities in which they are to be located. It seems likely that this co-operation will be easily secured, as the advantages of commercial aviation will be readily appreciated. It is feared, however, that those who co-operate in this way are likely to experience disappointment and discouragement when, after expending large sums, they find that what they have helped to build is more suited to military than to commercial usage. If this result follows, commercial aviation will receive a setback.

The selection and construction of landing fields for commercial aviation should not be left to military authorities. They should, of course, select and build fields necessary in the system of national defense, but their activities along this line should be generally understood to be purely military.

Congress, at the next session, as one of its first acts, should enact legislation which will place the regulation and control of commercial aviation under either a new department of aviation or in the hands of one of the existing departments accustomed to co-operate with industry and commerce. Because of the importance of this latter consideration, the bill to be presented by the Department of Commerce should be given special attention.

Export Trade Demands Common Sense

THIS matter of export trade is neither mysterious nor complicated. It is a simple business proposition and demands chiefly common sense.

It calls for analysis and caution and perspective to exactly the same degree as these are exercised in domestic trade. There appears to be more anxiety than is necessary merely because of a widespread notion that export trade is a complicated affair, requiring complicated handling.

No automobile manufacturer planning a campaign in a local section of the United States would start without first considering the field, the wealth, industrial and social conditions, highways, character of the people and other essential factors. He would not fix an appropriation without a study of the possibilities of business. He would not ask an artist, never west of the Hudson, to paint a sketch designed to have local color for an advertisement in the Rockies. He would not employ a sales representative for California merely because he was born and reared there or had traveled through the State as a Pullman conductor. He would not employ local New York idioms in an advertisement intended solely for Oregon.

And similarly in the development of export business, it is first essential to study the field comprehensively, build the advertisements to fit the customs, conditions and people, spend sums conforming to the business possibilities, employ artists who know the localities, write the publicity in the native language of the people and appoint sales representatives who know both the people and the commodity or a kindred product.

It is a matter of doing business in foreign countries with the same common sense that is exercised in this country.

The Day of the Inventor and Designer

NOT for a long time have the inventor and designer occupied such important positions in the automotive field as they do to-day. Many have complained that our industry has focused its attention on production and price to such an extent that it was almost impossible for a man with a new idea to get a hearing unless that idea had something to do with shaving a few cents off the cost per car.

There are numerous instances where inventors have been placed under contract, the seal of silence placed upon them, handsome salaries paid to them and their inventions never used. They were kept silent because while those who employed them realized the importance of their inventions, they did not want to upset production or undertake the work of selling something new.

Conditions are different now in many but not all the factories. It is recognized that next January's New York Show will disclose radical departures made by many of the oldest established concerns. We know of one concern that has contracted for thousands of engines of a radically different type from those now in use, provided certain specifications can be met. And according to all advices these conditions are not only being met but will be far surpassed. Another car manufacturer is on record as about to abandon the poppet-valve engine for one with a valve design of different type.

There are literally hundreds of new things in the factories and on the roads that will make their appearance next year, and knowing this the manufacturer is more ready to try out inventions and plans that look feasible than he has been since the early days of the industry when mechanical progress was marvelous in its rapidity.

This is a healthy state of affairs. With the fuel problem before us, with the demand for performance, economy and appearance more firmly impressed on us than ever, and with the knowledge that the markets of the world are open to us as never before, inventions which better the product should be given careful consideration. The countries which were involved in the war were jogged out of their mechanical and engineering rut by war's necessities, and it is but natural that in returning to peace pursuits they will make use of their added knowledge and stimulated initiative.

There has been much complaint in the past on the part of inventors that their work was not properly appreciated. There may have been justification for this plaint, especially in times of unusual prosperity when everybody was busy and disinclined to experiment with new things. But there is certainly none now.

Industrial Devastation in Belgium

A REPORT on the wanton devastation of the automotive plants in Belgium will be printed in AUTOMOTIVE INDUSTRIES, begining next week. The report was prepared by W. F. Bradley, European representative of this paper. Mr. Bradley obtained, after much difficulty, permission to tour Belgium and visit these factories to write a report and secure photographs exclusively for AUTOMOTIVE INDUSTRIES. He spent considerable time in these plants, noting the damage that was accomplished and gathering data as to how this was done and the extent of the damage, both to the physical plants and to the future trade.

Photographs accompanying this report are evidence of the thoroughness with which the German army and industrial leaders did this work. They continued the destruction until fifteen minutes before the Armistice became effective.

Practically all of the expensive motor building machinery in the Belgian factories is gone. Those machines which were available for use in the German war material factories or field repairshops were removed on official orders, but other machines were destroyed where they stood.

At the time this was under way, it was supposed that this was done chiefly to provide raw material for war manufacturing purposes, but Mr. Bradley finds that the present opinion is that this destruction of machines was planned and carried out with a view of eliminating Belgium as an automobile exporter after the war. This view is supported by the fact that Belgian factories were run chiefly for the export trade and were no mean competitor for the Germans.

Mr. Bradley's report is exhaustive and convincing and a document of importance as to German methods and objectives.

Latest News of the

Steps Toward Armistice in the Willys-Overland Strike

Settlement Is Expected by Monday—Company Explains Status of Controversy with Union and Its Beating on Competition—Other Toledo Labor Disputes Moving Toward Settlement

TOLEDO, May 22 (Special Telegram)—An armistice in the Willys-Overland strike seems near at hand, and probabilities are that the men will be back on their jobs and the plant running smoothly on Monday. Many of the men who are returning to work are being deputized so they can carry arms to protect themselves.

Conferences have been held all week regarding the Willys-Overland affair, and both sides have agreed to settle the matter by arbitration. The union workers insist that they are not giving any ground by agreeing to an armistice and are threatening to withdraw all union funds from Toledo banks. This would amount to about $2,500,000. A further demonstration was held on Sunday, when thousands of workers, led by a soldier in uniform, marched in a parade through the city and held a mass meeting opposite the police station.

The settlement of other labor controversies here also seems near. Of the 800 strikers of the Edward Ford Plate Glass Co., 400 have returned to work and the rest, it is said, will be back the beginning of the week. The men are returning to their old wages and old hours.

—

TOLEDO, May 20—Vice-President and General Manager C. A. Earl of the Willys-Overland Co. said to-day that the Willys-Overland plant would be opened Monday morning.

In a page advertisement in the Toledo paper Saturday, Mr. Earl restates the position of the Willys-Overland Co. in the present labor trouble. He sets forth that the automobile district council, which presented the demands causing all the trouble, did not represent the majority of employees. Out of 13,000 men and women who were at work on May 5, more than 7,000 remained at their places after those employees represented by the council had walked out.

When the walk-out was decided at a mass meeting, May 3, the only point voted on at that meeting was the question of hours. Approximately 1200 men were present when the vote was taken. Less than 900 men, not over 7 per cent of the total employees of the plant, voted for the walk-out. As a result of the extraordinary action taken by this very small number, instructions were issued to walk out on Monday, May 5.

"In justice to ourselves and to the many thousands of our loyal employees," states Mr. Earl, "the company did not and cannot recognize the right of a small group of men to determine our policy, and to so vitally interfere with the inherent rights of 13,000 employees, without having in any way the authority to represent or act for them.

"It is well known that the Willys-Overland Co. has always operated an open shop, without discrimination against any man, whether he be a member of a labor union or not."

In taking up the demands as presented to the company on April 27, the company first quotes the demands of the men and follows with the statement of the company's position.

Establish 8-Hr. Day

Regarding hours, the strikers ask for an 8-hr. day and a 4-hr. Saturday for the first shift, and 8 hr. with no work Saturday for the second and third shifts. In discussing this demand, the company states that it is convinced of the reasonableness and justice of the 48-hr. week. In restoring the 48-hr. working week after the suspension of war activities, the company informed the committee that competitive conditions demanded that it continue to operate on the basic 49-hr. week.

To concede a 44-hr. basic week as against a 48-hr. basic week would mean decreasing the working hours per year equivalent to a month's output. Such a plan would mean a big loss in earnings to employees, as well as a big loss to the company.

While the 48-hr. week working basis was established in good faith and in the belief that the majority of employees want Saturday afternoon off, nevertheless the company is willing to abide by the result of the majority vote of its employees and divide the week into six days of 8 hr. each, thus fully establishing the basic 8-hr. day.

Settlement of Overtime Pay

Regarding overtime, the strikers demand that all time worked after the established hours shall be paid for at double time rates. No employee shall be required to work on more than one shift in any given 24 hr., unless they are compensated at the rate of double time for such work performed. The union wants double time on Sundays and all legal holidays; election and primary days shall be 7 hours. The union demands limited overtime not to exceed 2 hours per day and 3 days per week. They also request that no overtime demand be made upon them by the company between June 15 and Sept. 15, except in case of emergencies such as breakdown in machinery and equipment. In answering this demand, the Willys-Overland Co. declares double pay for overtime an unreasonable request, which could not be sustained under relative competitive conditions. The company is willing to pay time and a half after the regular hours established for the 48-hr. basic week. Double time will be paid on Sundays and on the days observed as national holidays.

Representation Plan

Regarding shop committees, the union demands that employees shall elect a committee of three members in each department of every plant. These committees are to be recognized by the company as being the proper representatives of the employees to take up departmental grievances with the foremen of any department wherein a grievance has arisen. If this committee is unable to adjust said difference or grievance with the foreman of the department, then the grievance with the foreman is to be turned over to the Joint Shop Committee and the proper officer of the company for adjustment. The Joint Shop Committee shall not exceed 15 members and shall be selected by the employees.

The Shop Committee shall be recognized as the proper representatives of the employees in adjusting trouble which cannot be settled by the department committee and their foremen. Members of the Joint Shop Committees will be allowed the privilege of investigating grievances in any department that are brought to their attention.

In reply to this demand the company informed the employees that it had already provided a plan of representation of all employees. This plan gives employees the right to elect their own committees, which will work in conjunction with the management in the settlement of grievances, wages and working conditions.

Under the company's employees' representation plan, committees are elected in the various departments or divisions on the basis of one representative for each 200 or 300 employees. From the ranks of these elected committeemen five employees are elected by the committeemen themselves. The management also appoints five representatives. These ten men constitute the general board of adjustment to handle all matters which can-

Bill for Maintenance of the M. T. C. Introduced in Congress

Army Officials Urge Its Continuance as Separate Body—Work of Corps Commended by Gen. Pershing—Bill Provided for Disbandment of M.T.C. in Last Session

WASHINGTON, May 20—With the opening of Congress this week, considerable interest centers about the future of the Motor Transport Corps, the continuance of which as a separate body in control of the operation, maintenance and purchase will be urged by army officials. During the last session the army bill provided for the disbandment of the M. T. C. and the return to the old system under which the control of trucks and other motor vehicles would be placed under each separate division. This plan was followed prior to the war, when the Quartermaster Department, Signal Corps, Aviation, Engineer and other divisions each purchased and maintained their own supplies of motor vehicles, with a certain amount of confusion, conflict and a needless waste of labor. Amendments were made to the bill, however, by Congressmen who realized the value of maintaining the corps separately. The filibuster prevented its passage.

The consolidation of the motor interests in the M. T. C. as a separate organization eliminated the duplication of effort and tended to insure a standardization of army vehicles. It is planned to introduce a bill in this session which will continue the M. T. C. as a separate division and place the maintenance, design, production, procurement and operation of bicycles, motorcycles, cars, trailers and trucks under it and leaving tractors and tanks under the control of the Ordnance Department.

Army officers point to a recent letter received from General Pershing by Brig. Gen. M. C. Walker, in which General Pershing testifies to the efficiency of the M. T. C. as additional evidence of the need for a separate division.

It is anticipated that there will be some controversy about the continuance of the M. T. C. due to the fact that executive divisions of the War Department are planning to maintain the present control of the purchase of motor vehicles.

Following is the letter from General Pershing to Brig. Gen. Walker and the proposed bill which will make the M. T. C. a permanent organization:

"Brig. Gen. Meriwether L. Walker,
Director, Motor Transport Corps,
American E. F., Tours.

"My Dear General Walker:

"At this time when many officers and enlisted men are returning home and severing their connection with the American Expeditionary Forces, I am glad to take the opportunity of expressing to you, and the officers and men under you, my appreciation and thanks for what the Motor Transport Corps has accomplished.

"When war was declared, motor transportation was almost non-existent in the army. From the outset, the Motor Transport Corps had to meet the most difficult conditions, including its organization at a time when the demand for motor transportation at the front was the greatest; it always suffered from a deficiency of at least 70 per cent in required personnel and of 50 per cent in needed material. The handling of many different types of motors which had been ordered and shipped to France by the various services, combined with an entire inadequacy of spare parts, was another difficulty that had to be overcome.

"That the Motor Transport Corps was able to operate despite these handicaps and keep enough vehicles running at the front to supply the fighting troop speaks well for the energy and perseverance of your officers and men. Under all conditions of weather, on bad roads, often under heavy fire, at the front and throughout France, they labored cheerfully. Your well-considered plans would have soon borne fruit and resulted in a highly efficient service.

"In ending I cannot neglect the opportunity of thanking you personally for the energetic effort and enthusiasm you have displayed in your difficult task and which produced such fine results.

"Sincerely yours,
"JOHN J. PERSHING."

Section Referring to M. T. C. Provisions

The following is the section of the General Army bill for 1920 that refers to the M. T. C.:

For contingent expenses for Motor Transport Corps operations in the field, purchase of the necessary articles of office, toilet, desks, furniture, stationery, ice and water for office use when necessary, binding, maps, technical books of reference, professional and technical newspapers and periodicals, payment for which may be made in advance, and for other purposes incident to the Motor Transport Corps, services and expenses of necessary employees engaged in the Field Service, provided that the number of and total paid for civilian employees in the field service of the Motor Transport Corps shall be limited to the actual requirements of the service.

Provided, further, that the Secretary of War is hereby authorized in his discretion to rent or lease any building or part of building in the District of Columbia that may be required for the Motor Transport Corps during the fiscal year ending June 30, 1920, payment therefor to be made from this appropriation.

Provided, further, that the service of skilled draftsmen, expert automotive engineers, mechanical engineers and such other services as the Secretary of War may deem necessary may be employed only in the office of the Chief of the Motor Transport Corps to carry into effect the various appropriations: Provided, that the expenditure on this account for the fiscal year 1920 shall not exceed $428,710, the Secretary of War shall in the annual estimate for the fiscal year ending June 30, 1922, report to Congress the number of persons so employed, their duties and the amount paid to each.

For maintenance of the necessary automotive vehicles of the army including repairs, spare parts, etc., operation of motor vehicles, including gasoline and lubrication, hire of automotive equipment when necessary, maintenance of repair shops and units and other purposes in connection with design, production, procurement, housing, storage, maintenance, repairing, operation and replacement of Motor Transport Vehicles for the Army including accessories and mechanical supplies, no part of which to be expended for clerical employees in any capacity.

Provided, further, that in this act the term Motor Transport Vehicles wheresoever used will be construed to mean all bicycles, motorcycles, automobiles, trailers and trucks, that are fitted or may be fitted for passenger or cargo transportation. Tracklayer tractors, designed primarily for traction purposes, and tanks are not held to be Motor Transport Vehicles.

Provided, further, that the Motor Transport Corps shall be charged with design; production; procurement; housing; storage; maintenance; repairs; operation; assignment and replacement of all Motor Transport Vehicles; spare and repair parts; tools; accessories, and mechanical supplies of all Motor Transport Vehicles for the Army as herein-before described. Provided, further, that the Motor Transport Corps shall under such regulations as may be approved by the Secretary of War, establish and operate such garages, parks, depots and repair shops as may be necessary and to procure, organize, assign and technically train all persons necessary to the proper operation thereof.

Provided, further, that the procurement of Motor Vehicle chassis required for carrying special type bodies for the Army will be made under the direction of the Chief of the Motor Transport Corps.

Provided, further, that the procurement of special motor vehicle bodies not designed for passenger or cargo transportation or for Motor Transport purposes, and tracklayer tractors and tanks as hereinbefore described may be made under the direction of the bureau, corps or department for which such special equipment is designed.

Provided, further, that the procurement of special motor vehicle bodies shall be made only after the design thereof is approved by the Chief of the Motor Transport Corps.

N. A. C. C. to Make Formal Request for Reclassification of Chassis

NEW YORK, May 21—The National Automobile Chamber of Commerce is preparing to make a request that the revenue tax be removed on automobile parts and trucks. Representation is to be made to-morrow before the Internal Revenue Department for a reclassification of the truck chassis so that it will not be classified as a part and thus subject to 5 per cent tax, but will be classed as a complete vehicle and subject only to the 3 per cent tax.

The Chamber will hold a meeting of its export managers on June 6 for the purpose of mapping out a definite foreign trade program with the possibility that some form of foreign trade co-operation, as made possible in the Webb Act, may be worked upon.

Goodwin Leaves Cadillac

DETROIT, May 21—Edward W. Goodwin, engineer of the body division of the Cadillac Motor Car Co., has resigned. He will take a month's rest and then open an office here for car designing, detail and building.

Great Britain Developing Commercial Aviation Program

Large Military Air Force Maintained—Manufacturers Continue Activities—Commercial Enterprises Starting—International Air Rules Modified at Paris

LONDON, ENGLAND, May 1—The Government is conducting its military aerial program with the greatest secrecy. Not much positive information can be gained. While the demobilization of the army continues, the air force is remaining at the same figure as when the armistice was signed. The present force is believed to be 40,000 officers and 310,000 men. This means that Great Britain will continue indefinitely a large air force. The commercial aircraft manufacturers are continuing activities. None of the larger firms have slackened work, although many of the small ones have. But very few have closed down.

Handley-Page, Ltd., is now working on the following contracts:

1. Fulfilling Government contracts. They still have upwards of 1000 machines to build.
2. Running a passenger service at Hendon with five machines carrying 11 passengers apiece. Each passenger pays $10 a flight.
3. Several small contracts for the circulation of papers. The Daily Mail, the Daily Chronicle, and the Daily Telegraph, have ordered several machines apiece to be especially adapted for paper-carrying to assist in the rapid circulation of their papers.
4. Building a special machine with four engines to attempt the Atlantic flight.
5. Building a series of specially designed machines to fly Marconi wireless apparatus across the Tibetan desert to China, which has been tried by land but was found to be impossible.

Similarly the Vickers Ltd., are fulfilling a contract for 5000 double-engined bombers, of which they have so far only completed 504, so recently was the contract given.

Gets Exclusive Mail-Carrying Rights

Holt Thomas has obtained the sole rights from the British and French Governments for the carrying and delivery of mails between England and France. He is relying on this for his bread and butter, when he gets through with his present Government contracts. He is also running the present passenger service between London and Paris.

The Government is rapidly getting rid of all its obsolete types of machines by selling them at auction. Good airplanes with engines often have sold at from $1,500 to $3,000. The buyers are usually pilots of the Air Force, who have been demobilized, and who are starting in the passenger carrying business for themselves.

With regard to the smaller works, which are now left with no Government contracts, the majority are working on altogether new lines which utilize much the same type of material, and much the same type of skilled labor, as the airplane work they have been doing.

Major General Sir Frederick Sykes, K. C. B., Controller General of Aviation in Great Britain, made the following statements in a recent address to the heads of firms interested in the manufacture of aviation products:

"By May 1 the ban which has been placed on civil aviation during the war will be removed. As a result of the conferences in Paris, a draft convention has been drawn up, and it is on that that our home regulations for civilian flying will be based. It does not apply to British military aircraft.

"The first point is naturally, Who may fly? Any person wishing to fly aircraft carrying either passengers or goods must obtain a certificate to the effect that he is properly qualified to do so, and a license. Rules have been agreed on in Paris for the control of aerodrome traffic, and will be attached to the regulations, and once in the air, a definite rule of the air will be adhered to.

Will Prohibit Flying in Certain Areas

"So far as national secrecy is concerned, there will be certain prohibited areas over which none will be allowed to fly. An obvious point which has been lost sight of is the danger of alien undesirables and foreigners being landed in this country, without the police and military authorites knowing of their advent. The aliens restriction order has had provisions inserted, which cover all persons arriving in this country by air.

"The danger of smuggling by air is a very real one, and for the present it has been decided that all airplanes incoming from overseas shall only be allowed to land at four fixed aerodromes, the names and locations of which I shall give out at a later date. Persons landing elsewhere will be taken into military custody pending investigation. If, however, we find that commercial traffic develops, especially with Europe, we can always increase the number of aerodromes by an arrangement with the Customs.

"In military aviation I may say that we, through force of circumstances, lead the world. It is for us to see that we do not lose the advantage gained during the war, and that we also hold the same position in civil aviation. Flying is an international affair, and the first step has been taken to form an international code with Europe. This was the object of the Paris conference.

"Among other things agreed upon by this conference is that every machine shall be assigned a registration number, and also a nationality mark. Before these numbers are allotted, however, each machine would be inspected for design, construction, material, and actual performance in the air. All machines will be certified for a certain definite load or number of passengers, which it will not be allowed to exceed under any circumstances. Each machine will be compelled to carry log books, and will not be allowed to fly more than a certain number of hours without overhaul.

"No articles whatsoever will be allowed to be thrown overboard with the exception of water or very fine sand, as heavier articles would be likely to cause injury to people down below."

Major Foot, who is conducting a passenger carrying air line, reports that during the four days of Easter holidays his machines carried 973 passengers without accident.

Additional International Air Rules

PARIS, April 27—The Aeronautical Commission of the Peace Conference has issued an official communiqué which outlines some additional clauses of the probable international regulations for aerial transportation. In part the communiqué says:

"The Commission has decided as a matter of principle that certificates of airworthiness in the case of the aircraft and certificates of competency in the case of the crew are to be recognized as universally necessary in international flying.

"The right of flying over a State from frontier to frontier is recognized, subject to the safeguard that the State flown over may compel a landing in the interests of national security, or, in other words, where reasonable suspicion exists that the flight is not bona fide. In the interests of domestic control by each State there are provisions as to the carriage of various papers of identity, etc., upon the aircraft, and the prohibition of the carriage of dangerous articles is also provided for.

"The final provisions include an arbitration clause for the settlement of disputes and a clause which definitely places the convention on a peace basis as not affecting the rights and duties of belligerents or neutrals. Military aircraft are placed in a class apart, and may not fly outside their own country, except by the special authorization of a State visited by them, in which case they are to be treated according to the usual rules prevailing in the case of ships of war."

Automotive Activities in England on Increase

LONDON, ENGLAND, May 2—The automotive activities throughout the United Kingdom are showing considerable increase. The budget introduced April 30 makes no changes that concern American motor cars, but it shows a decided preference for cars manufactured in British colonies. An American car for instance would pay 33 1/3 per cent import duty while a British colony car would pay 2/3 less.

The Ford Co. has resumed building operations at its new factory at Brook Green, Hammersmith, London, and is now adding a third floor. The plan is eventually to make the building five stories. This building so far has been used more as a repairshop than as an assembly plant, but eventually will be a factory. The Ford interests have announced that the first castings have been produced at the Fordson factory in Cork. There was a celebration of this event at the factory.

The Pneumatic Tire Committee of the Society of Motor Manufacturers and Traders has taken up the work of international standardization of all solid tires. The work undertaken by this committee follows that of committees representing the British Rubber Tire Manufacturers' Association and the British Engineering Standards Committee. The object of this work is to eliminate a great number of types and sizes now on the market and to make tires interchangeable throughout the world. T. H. Woollen is chairman of this committee.

Westinghouse Dividend

Westinghouse Electric & Manufacturing Co., Pittsburgh, 2 per cent quarterly dividend, common and preferred, common payable July 31, preferred payable July 15, both to stockholders of record July 15.

New Navigating Instruments Made for Transatlantic Flight

Take Account of the Altered Conditions Under Which Observations Must Be Taken and Permit Very Rapid Determination of Results —Equipment of Navigator's Cockpit of NC Planes

NOVEL instruments, especially designed for use in oversea navigation, are employed for the first time by the U. S. Navy-Curtiss seaplanes in the transatlantic flight.

No airplane has ever flown far enough out to sea to warrant the use of the sun, moon and stars for fixing a geographical position, as is done on seagoing ships. Navigation, therefore, on a transatlantic flight is new and untried, and it has been necessary in preparing for this flight to design three new instruments for navigational use: 1. An aerial sextant; 2, a drift and speed indicator; 3, a course and distance indicator.

A feature of the aerial sextant, known as the Byrd sextant, invented by Lieutenant R. E. Byrd, is that a bubble in a tube takes the place of the sea horizon and observations. A specially constructed lens is used in sighting the bubble, which is reflected in a mirror. The sun is reflected in another mirror. The observer brings the sun tangent to a line at the same time he brings the bubble tangent to the line. That gives the altitude of the sun. This is of especial value, as the aviator is often above the clouds. and even when flying at low altitudes the horizon is too dim to be seen clearly. With this new aerial sextant the curvature of the earth does not have to be taken into consideration in calculating position. The bubble is lighted at night, so that night observations may be taken.

New methods of astronomical calculations also have been devised which enable the navigator to make his calculations in a fifth of the time that was formerly necessary. A zenithal projection chart of the Atlantic Ocean has been specially constructed for this purpose. This chart, a new invention, does away with difficult mathematical calculations, enabling the aviator to determine his position in a few minutes.

Another great problem of the sea-air navigator is the calculation of the speed and direction of the wind, both day and night. In spite of the reliability of the compass, it can only give the course upon which the craft heads, and in determining the true course, proper allowance must be made for the sidewise drift caused by the wind. For example, a wind blowing 30 miles an hour towards the side of the plane will blow it 30 miles an hour out of its course. This fact alone makes the navigation of the air far more difficult than the navigation of the sea.

To overcome this difficulty bombs have been invented which ignite upon striking the surface of the water and give a dense smoke and bright light for ten minutes.

An instrument is used in conjunction with this bomb which enables the navigator to determine the velocity and direction of the wind by sighting on the smoke in the daytime and the lights at night. This instrument, called the speed and drift indicator, has proved successful.

When the navigator has found the speed and direction of the wind, he must then be able to calculate the course to steer towards the Azores to allow for this wind. To do this an instrument has been designed to solve the triangle of forces, thus doing away with cumbersome mathematical calculations.

The navigator's cockpit is in the fore part of the boat and is equipped with a chart board, a chart rack and lights. He also has a specially designed headgear for telephonic communication with the pilots so that he can direct them when to change course. The noise from the four big engines is so great that it is impossible to hold conversation except with specially designed telephonic apparatus.

The navigator also has instruments which show him the altitude of the plane and the time the sun keeps with the Greenwich meridian, because in going to the eastward so rapidly it is difficult to keep the correct time. In going from Newfoundland to the Azores, over two hours is lost in a period of 20 hours, so that the navigator must be very expert in order to allow for this loss in time in making his astronomical calculations.

In aerial navigation, positions must be determined very quickly. The navigator sits down to work out his "sights," to fix his position, and by the time he arrives at results he will be far from his calculated position unless he works out his calculations very rapidly, which these instruments enable him to do.

—

Outstanding Aircraft Contracts

WASHINGTON, May 19—Of the Air Service contracts outstanding Nov. 9, 1918, which totaled $672,849,000, terminations to date include a total of $498,-039,000. Deliveries since the signing of the armistice aggregate $160,000,000 and contracts still in force amount to $14,-810,000. In percentage this results in 74 per cent of the contracts terminated, 24 per cent delivered, and 2 per cent remaining in force.

—

Dealer Contracts for 150 Airplanes

CHICAGO, May 19—The James Levy Motor Corp., Buick dealer, is distributer for the central west for the United Aircraft Engineering Corp. of New York. He has contracted for 150 of the Canadian JN-4 training planes.

These planes are being sold at $2500 and are part of the equipment bought by the United Aircraft Engineering Corp. from the Canadian Government. They have a 90-hp. eight-cylinder OX-5 "V" type engine, double control, and weigh 1600 lb. They are capable of from 80 to 90 m.p.h.

—

Manufacturers' Association Plans Export Trade Combine

NEW YORK, May 21—At the foreign trade session of the National Association held here last night it was proposed to form an export corporation to operate under the Webb-Pomerene law in the various Latin-American republics. This will be known as the Namusa South American Corporation and membership in it will be limited to members of the association. The plan was roughly outlined, but details are yet to be agreed upon. Approximately 60 groups of manufacturers are provided for, each concern owning one share of stock.

—

Flying Fields to Be Retained

WASHINGTON, May 19—Fifteen flying fields and five balloon schools are to be held by the Air Service as permanent training fields, as follows:

Government Owned

Rockwell Field, San Diego, Cal.
Langley Field, Hampton, Va.
Post Field, Fort Sill, Okla.
Kelly Field No. 1, San Antonio, Tex.

Leased—to Be Purchased

March Field, Riverside, Cal.
Mather Field, Sacramento, Cal.
Carlstrom Field, Arcadia, Fla.
Dorr Field, Arcadia, Fla.
Ellington Field, Houston, Tex.
Park Field, Millington, Tenn.
Souther Field, Americus, Ga.
Selfridge Field, Mt. Clemens, Mich.
Scott Field, Belleville, Ill.
Chanute Field, Rantoul, Ill.
Kelly Field No. 2, San Antonio, Tex.

BALLOON SCHOOLS

Government Owned

Lee Hall, Va.
Ft. Crook, Neb.

Leased—to Be Purchased

Arcadia, Cal.
San Antonio, Tex.
Ft. Omaha, Neb.

—

45,270 Planes in 9 Months

WASHINGTON, May 16—France, Great Britain and Italy produced 45,270 airplanes in the 9 months from Jan. 1 to Oct. 1, 1918, of which 79 per cent were service planes and 21 per cent were training planes. Great Britain produced 23,509; France, 1833, and Italy, 2928 airplanes.

—

British Motor Trading Corp. Opening Branches Throughout England

LONDON, ENGLAND, May 2—The British Motor Trading Corp., Ltd., has been organized with a nominal capital of $10,000,000 to establish a chain of garages and motor salesrooms throughout England. The company announces that it will carry large stocks of parts for popular cars. The company is said to have placed an initial order for Crossley cars amounting to $5,000,000. These cars will be sold throughout England and Scotland.

90% Contract Claims Filed With Boards

Large Claims Still Pending—Plan for Sale of Surplus War Material

DETROIT, May 20—Having practically all of the smaller war contract aircraft and ordnance department claims in this district cleaned up, local claim adjustment boards are now engaged in routine work awaiting the presentation of a score or more large claims still pending. These big claims represent nearly 40 per cent of the total value of all contracts in this district. The boards have scores of men aiding the factory organizations in compiling the required data and excellent progress is now being made.

Among the claims still outstanding are Packard, Ford, General Motors, Willys-Overland, Lincoln, Fisher Body, Wilson Body, and a number of others. Approximately 90 per cent of all claims have been filed with the boards and about 50 per cent approved at Washington to date. The aircraft board expects to close business between June 1 and June 15. Ordnance adjustment business will be wound up about June 30.

Both boards, however, will maintain material disposal departments, which may be in operation for over a year. These departments face the huge task of selling approximately $85.000,000 worth of machinery without shaking the stability of the machinery market.

Surplus Material for Disposal

Aircraft officials estimate that it must dispose of between $40,000,000 and $50,-000,000 worth of machinery, and the Ordnance Board has nearly the same amount. About 75 per cent of this machinery will be sold to the firms for which it was purchased and installed. The remaining 25 per cent will be sold in co-operation with machinery dealers.

The system for the sale of this machinery is simple but practical. A company may have installed a Government machine valued at $1000 and proposed working it on an order for 1000 certain parts, calculating that the value of the contract, when complete, would have absorbed the cost of the machine. The Government however cancelled the contract when but 500 parts had been complete, leaving the machine 50 per cent unpaid for.

The Government will estimate that inflated war prices caused the machine to sell 30 per cent higher than standard price and will therefore deduct that amount from the price which the company will be asked to pay. Wear and tear covering the period of its operation will also be deducted. This will range from 15 to 40 per cent. When this depreciation as well as the price reduction is substracted from the 50 per cent initial cost of the machine, which had not paid for itself due to contract cancellation, the cost of the machine to the company will range between $200 and $300. About 60 per cent of bureau of aircraft machinery has already been sold on this basis.

The machinery which is useless to the company which used it for war work, will be removed and sold, but the sale will be conducted in co-operation with machinery dealers. For instance, if a company bids for this Government machinery, the bidder will be obliged to purchase a machine from the dealer for every machine purchased from the Government. The Government machine will be disposed of at a price based upon market reduction, depreciation, etc., but a standard price must be paid for the new machinery.

The officials do not desire to remove machinery from a plant, place it in storage and keep it until a purchaser is found. It will exert every effort to sell the machinery to the company which used it for war work and will make further discount to such firms if they purchase it.

President Emphasizes Industrial Needs

WASHINGTON, May 20—The industrial needs of the nation were the dominant features of the message from President Wilson to Congress, which opened here this week. He asked for:

Labor reforms that will democratize industry and bring full recognition of the rights of both the employers and employees.

Far-reaching government assistance for demobilized soldiers through the Department of the Interior which he asks to be given the necessary appropriations to develop hitherto uncultivated regions for the returning soldiers, and through the Department of Labor, which he requests be allowed to continue its employment service.

Foreign trade policies tending to establish friendliness between this country and all other nations.

A bargaining tariff so that we have a weapon of retaliation in the event that other governments enact legislation unequal in its bearing on our products as compared with the products of other countries.

Repeal of excise taxes on various manufactures and taxes on retail sales.

Return of the railroads and telegraph and telephone with legislation that will protect the interests of the owners and the nation.

Americans to Study European Aviation

WASHINGTON, May 19—A complete study and investigation of civil aviation as being developed in Europe will be made by Assistant Secretary of War Benedict Crowell and a number of military and civil aviation authorities who will leave for Europe on May 24.

The party includes Lieut. Col. James A. Blair, of the general staff; S. S. Bradley, of the Manufacturers' Aircraft Association; G. H. Houston, president of the Wright-Martin Aircraft Corp.; C. M. Keys, vice-president of the Curtiss Airplane & Motor Corp., and Howard Coffin, of the Council of National Defense. Col. Halsey Dunwoody, chief of the air service on overseas, will join the party in France.

Hudson Motor Co. Formed to Handle Hudson Sales

DETROIT, May 21—The Hudson Super Six and Essex in Chicago territory, formerly handled by the Louis Geyler Co., will hereafter be handled by the Hudson Motor Co. of Illinois, under active direction of J. R. Histed.

War Department Buys 200 Night Bombers

Bids Received Range from $19,-500 to $60,000 for Different Quantities

WASHINGTON, May 21—The War Department will place orders this week for 200 night bombers of the Glenn-Martin type. Bids have been received from the Glen L. Martin Co., the Curtiss Aero & Motor Corp., the Gallaudet Aircraft Corp., the Boeing Airplane Co., the Liberty Iron Works, the Unit Construction Co., the L. W. F. Engineering Co. and E. Elias & Bros. Prices bid range from $19,500 to $60,000 each. The prices vary widely because the bids are for different quantities. Following is the complete tabulation of the bidders, quantities bid on and prices:

Bidder	No. of Planes	Unit Price	Total
Glen L. Martin Co., Cleveland, Ohio	50	$37,875	$1,893,750
Curtiss Aero & Motor Corp., Buffalo, N.Y.	50	25,000	1,250,000
	100	21,000	2,100,000
	150	20,000	3,000,000
	200	19,500	3,900,000
Gallaudet Aircraft Corp., East Greenwich, R. I.	30	31,000	930,000
	50	30,500	1,525,000
	100	29,500	2,950,000
	200	29,052	5,810,400
Boeing Airplane Co., Seattle, Wash.	50	37,750	1,887,500
Liberty Iron Works, Sacramento, Cal. ...	200	29,500	5,900,000
Unit Construction Co., Philadelphia, Pa. ...	25	34,740	868,500
L. W. F. Engineering Co., College Point, N. Y.	50	29,800	1,490,000
	100	27,800	2,780,000
	200	24,950	2,990,000
E. Elias & Bros., New York	1	60,000	60,000
	5	55,000	275,000
	10	50,000	500,000
	25	45,000	1,125,000
	50	42,500	2,125,000
	100	41,000	4,100,000
	200	39,750	7,950,000

Truck Tax Reopened

NEW YORK, May 22—The Treasury Department ruling covering the tax on motor truck chassis is being reconsidered. Following protests from 57 dealer associations, including the National Automobile Dealers' Association, Commissioner Roper telegraphed the N. A. D. A. as follows: "Ruling regarding tax on chassis being reconsidered. When decision is rendered you will be notified." The ruling in question classifies a truck chassis as a part and as such requires a tax of 5 per cent. The contention is that a truck chassis is a sales unit and should be taxed as a complete unit at 3 per cent.

Plan Committee on Aeronautics

WASHINGTON, May 20—A resolution was offered to-day in the Senate authorizing the Committee on Rules to report a Senate committee to be known as the Committee on Aeronautics. The general purpose and functions of the committee will be to consider all matters pertaining to aircraft and aviation.

French Motoring Restrictions to Be Removed

PARIS, May 19 (Special Cable)—There is strong reason to believe that the motoring restrictions limiting travel distances will be removed this month.

The French gasoline supply is now entirely satisfactory.

Shortly after the first of the year, all gasoline purchase restrictions were removed, but travel was restricted within a radius of 30 miles of one's home. Travel was forbidden in the army zone and in the devastated regions. The removal of such limitations will throw the devastated area of France open to visitors this summer, and will doubtless lend added impetus to car production in France.

—

Milton Wins at Uniontown

UNIONTOWN, May 20—Tommy Milton, driving a Duesenberg special, finished first in the Victory sweepstakes speedway race here yesterday, covering the 112½ miles in 1 hr. 10 min. 9.32 sec., averaging about 96.21 m.p.h. The race, which was scheduled to open the American racing season on Saturday, was postponed until yesterday because of rain.

Louis Chevrolet in his Frontenac special came in second.

Willys-Overland Strike

(*Continued from page* 1132)

not be satisfactorily disposed of by the departmental shop committeemen. This plan provides for the election of committeemen by all men, including both union and non-union men, and gives fair and equitable representation to the entire shop.

Concerning female employees, the union asks that they be allowed equal pay for equal service and not be allotted tasks disproportionate to their strength. The committee states that female employees would be allowed equal pay for equal work on occupations ordinarily performed by men, and would not be given tasks disproportionate to their strength. Consistent with this policy, the company established a starting rate of 30 cents per hour for women, and installed rates in excess thereof up to 45 cents per hour.

Company Refuses Wage Increase

Regarding wages, the demand sets forth specific rates for only die makers, tool makers, die sinkers, machinists, specialists, inspectors, helpers, truckers, sweepers, elevator operators, drop forgers, blacksmiths, block and machine operators, heatrs, helpers, hammer drivers, stationary engineers, firemen, repairmen, heat system men, oilers, boiler washers, flue blowers, coal passers, mail order department men, sewing machine operators, top and body trimmers, sheet metal workers, press and bench men, solderers, helpers, pipe fitters and helpers. The increases in rates demanded were a minimum of 15 cents per hour in some cases and 25 cents per hour in other cases.

The Willys-Overland Co. in reply to this demand states that increases of 15 cents per hour to all employees and 10 per cent additional for second and third shift employees would not be granted and that the company could not afford to make a horizontal increase.

Trailer Manufacturers Want Uniform Laws

Executive Committee Passes Resolution Favoring National Highway Commission

NEW YORK, May 19—Uniform legislation and the promotion of a better public knowledge of the trailer and its uses were high points in the program outlined at an all day meeting of the executive committee of the Trailer Manufacturers' Association of America held in Association offices, 110 West 40th Street, Saturday.

As a first step it was decided to ask all members for suggestions for provisions relating to the regulation of trailers, and to incorporate these in recommendations to be sent to the Highway Industries Association with a request that they be embodied in the uniform traffic bill which was drafted by a joint committee representing the Highways Transport Committee of the Council of National Defense, the Association of State Highway Officials, the National Automobile Chamber of Commerce, the Highway Industries Association and the American Automobile Association.

It was also decided to work in conjunction with interested organizations to keep in close touch with proposed legislation, with the object of obtaining proper laws that will afford protection to the highways and their users without unwisely checking the development of economical and expeditious transportation by highway. To this end, it is proposed to arrange for the introduction of a uniform traffic bill embodying reasonable trailer regulations in the various state legislatures next winter and to get prompt advice of all other bills introduced affecting trucks and trailers.

Contact is to be established with state and local motor truck and team owners' associations, automobile clubs, good roads associations and commercial organizations, and to furnish them information and suggestions for action to be taken with respect to the various measures.

Endorse Highway Commission

As an instance of this purpose, the executive committee passed the following resolution:

Resolved, That the Trailer Manufacturers' Association of America favors the creation of a Federal Highway Commission and the construction and control of a system of national highways by the United States Government through such a commission, as provided in the Townsend bill introduced during the last session of the 65th Congress, and urges the early passage of such a measure by the 65th Congress with a view to providing better military defense, facilitating interstate transportation of persons and goods, reducing the cost of haulage by highway, increasing the production of foodstuffs, raising the standard of education and living in rural sections, and uniting the thought and sentiment of the people of the country through more frequent and easy intercourse.

In the matter of general promotion work, it was decided to make a report to members and some other trailer manufacturers covering an investigation that has been made into the merits and advantages of national publicity, and to begin efforts immediately to increase the membership of the association with a view to providing a sufficient fund for the purpose. The Southern Motor Manufacturing Association, of Houston, Texas, is the fifteenth member.

Trailer Standards Committee

A Trailer Standards Committee was appointed to confer with the Trailer Sub-Division of the Truck Standards Division of the Society of Automotive Engineers in all matters pertaining to standardization of trailers, trailer hitches, etc. The members are: W. R. Hudson, engineer of the Troy Wagon Works Co., chairman; H. G. Farr, engineer of the Martin Rocking Fifth Wheel Co., and H. W. Perry, general manager of the association.

A resolution was passed thanking the National Automobile Chamber of Commerce and R. A. Brannigan, of the N. A. C. C., for their efforts in pointing out to the Commissioner of Internal Revenue that trailers and semi-trailers are not taxable under the Revenue Act of 1918. The Treasury Department, in Regulations 47, just issued, rules that 2-wheeled and 4-wheeled trailers are exempt.

The committee considered the question of advisability of including motor truck routes as common carriers to be regulated as to routes, rates and stock issues by the Interstate Commerce Commission, as proposed tentatively by Congressman Esch. No decision with regard to recommendations was reached, but it was the general feeling that while a certain amount of regulation might be beneficial, insufficient experience in the operation of motor truck transportation lines would make it difficult and inadvisable to establish a fixed scale of shipping rates and that federal control over the organization and financing of such lines at this time might retard development of such transportation.

Standardized Cost Accounting

Use of a standardized cost accounting system for motor trucking was approved and, while not endorsing any specific system, it was the sentiment of the committee that trailer manufacturers should urge truck and trailer operators to install a uniform system so that results can be compared. The general principle of controlling trailer brakes by air pressure was also endorsed.

In July a general meeting of members of the Trailer Manufacturers' Association will be held. The date and place have not yet been set, but Rochester may be selected.

Members of the executive committee in attendance at the meeting were: President W. E. Ferris (Ohio); Second Vice-President R. C. Sykes (Troy); W. R. Bonds (Detroit); C. H. Martin (Martin); H. M. Wood (Trailmobile), representing J. C. Endebrock, secretary-treasurer; and H. W. Perry, manager of the association. Several territorial representatives of member companies were also present, including A. R. Miller of Philadelphia.

New Basis for Tractor Engine Ratings

Tractor Standards Committee of S.A.E. Discusses Uniform Standards, Rating and Legislation

CHICAGO, May 19—A more uniform basis of tractor engine ratings, more conservative rating standards and uniform and fair legislation from State Assemblies were among the topics discussed at the meeting of the Tractor Standards Committee of the Society of Automotive Engineers, May 9.

Representatives of the International Harvester Co., Advance-Rumely, Aultman-Taylor, Parrett Tractor Co., in addition to other members of the committee, including Prof. Chase of the University of Nebraska, were present.

After looking over the reports of the Winnipeg, Salina and other demonstrations it appeared foolhardy to the committee to try, with any degree of consistency, to rate tractors from the results obtained in field tests on account of the wide variation of conditions. What tractor makers generally are after now is some basis of comparison.

After considering many proposed plans for bringing this about the committee felt that the best solution at the present time would be a method similar to that used in rating cars and trucks, inasmuch as the latter method is used satisfactorily and has been accepted by all the states in issuing licenses. While it is true that a car of one make, having the same rated horsepower as a car of another make, might out-perform the latter, there nevertheless is a basis upon which to make a comparison.

The new proposed rating would establish a definite single basis on which makers could rate the ability of their tractors and incidentally make it easier for the farmer to make a selection.

Car engines are rated on about 11,733 cu. in. displacement per minute per horsepower. From the fact that cars invariably use gasoline and the duty is much lower than tractor engines, it was decided to adopt the following formula basis on about 13,000 cu. in. displacement per minute per horsepower for tractors:

$$\frac{.7854\ D^2\ LRN}{13{,}000}$$

where D is the diameter in inches of the bore, L the length of stroke, R the number of revolutions per minute, and N the number of cylinders.

Under the present rating of tractors the piston displacement runs anywhere from about 9,000 to as high as 16,000 cu. in. per min. per hp. An average taken from 12 different makes of tractors shows a piston displacement per min. per hp. of 12,696, based on the tests at Columbus, Ohio, in 1918. Also the concerns who are making tractors in any quantity come very close to the proposed 13,000 figure. Obviously if the new rating scheme is put into effect, it will mean a change in the rating of some tractors where the displacement is figured on a piston displacement per min. per hp. of less than 13,000.

The new formula may be only temporary, but it offers something for the industry to work on. It is likely that in time it will be changed, possibly reduced. In any event it will be necessary to rerate tractors whose ratings are now based on less than 13,000 cu. in. to comply with the Nebraska and other state laws.

—

Tractors for Demonstration at Denver

DENVER, May 20—The following makes of tractors will participate in the tractor demonstration to be held here June 8 to 14:

All-Work	Illinois
Aultman-Taylor	I. H. C.
Avery	Lauson
Best	Leader
Case	Moline
Cleveland	National
Eagle	Parrett
Emerson-Brantingham	Rumely
Fair	R & P
Fordson	Sandusky
Four-Drive	Twin City
General Motors (GMC)	Turner
Gray	Wallace
LaCrosse	Wisconsin
Hart-Parr	Waterloo-Boy
Huber	Wheat
Holt	Bullock
	Bailor Motor Cultivator

—

New Truck Tread Attachment

DETROIT, May 15—William Coatworth and M. A. Zoulek have formed the Coatworth & Zoulek Mfg. Co. here to make a truck tread attachment. It is used on both rear wheels, providing a track on which the wheels run. The attachment is made of hard wood blocks, with pipe spacers between, through which a steel cable passes. The shoes provide traction and the tread is claimed to enable a truck to pull out of mud holes.

Improved Oil-Pressure Regulation in Liberty Engine

(*Continued from page* 1127)

oil in the pressure-gage pipe may congeal so that the gage will not register until thoroughly warmed. It is always best to drain the entire system after flights. Unless great care in warming-up is exercised, burnt-out bearings may result.

The oil and lubrication branch of the Bureau of Aircraft Production has developed an engine water heater which can be attached to each engine in active service. This consists of a small stove with several gasoline burners and a copper coil. The water from the engine cooling system circulates through this copper coil and is returned into the top of the radiator. The heater should be attached to the engine as soon as it comes in from the flight (it is only necessary to make one connection in the water return line), and it will keep the engine circulating water and oil warm. Priming the cylinders with excessive raw gasoline will wash the oil film off the cylinder walls, and scored pistons may result. Gasoline for priming should be used very sparingly, and only through the hand dash primer to the petcocks on the intake manifolds.—*Liberty Engine Service Bulletin No.* 8.

Tax on Truck Chassis Fought by N. A. D. A.

Taxed 5 Per Cent Because Classed as Part—Dealers Claim It Is Taxable at 3 Per Cent

ST. LOUIS, May 17—A vigorous fight against the ruling of the Internal Revenue Bureau that a truck chassis is a "part," and as such taxable at 5 per cent, is being made by the National Automobile Dealers' Association, through Harry G. Moock, business manager. In addition to a protest to Commissioner Roper, the association has asked the secretaries of 57 dealers' associations throughout the country, not only to wire protests on behalf of the organizations, but to have each individual member do so. The ruling is effective Feb. 25, although just announced.

The telegram of the N. A. D. A. to Roper follows:

"Treasury decision, Article 15, Regulation 47, classifying truck chassis as a part is contrary to all sales usages. Truck chassis is a sales unit, and is the basis of all truck sales regardless of the type or kind of body used. Therefore, classification as a part is not only an injustice, but greatly impedes truck sales and is a penalty on business. Revision of decision, therefore, should be made so that truck chassis when sold complete as a unit takes 3 per cent tax, which we believe was intended when the 1918 revenue bill was framed."

Here are the reasons Mr. Moock gives for the revision of the ruling:

"Dealers have been selling on the presumption that a chassis is a truck and, therefore, taxable at 3 per cent. Thus the ruling will cost the dealers thousands of dollars. The 1918 decisions of the revenue bill classified the chassis as the unit of sale. For three months the dealers have been parting with truck chassis with only a 3 per cent tax against them, as passed on by the manufacturer. It is very probable that the manufacturers, because of their contracts, will be able to collect the additional 2 per cent from their dealers, but the dealers, having completed the transaction with their customers, will be unable to collect the 2 per cent additional thus passed on."

A special war tax bulletin has been sent by the N. A. D. A. to its members, giving complete information on the decisions of the treasury department on the application of the new tax. One of the radical changes is the ruling that whenever a manufacturer overpays the tax to the government in one month he may take a credit on his next monthly return instead of having to pay the full amount due for the month and applying for a refund for the amount erroneously paid the previous month.

—

Booth Making New Bumper

OWOSSO, MICH., May 19—W. S. Booth, formerly of the Field Mfg. Co. and Biggam Trailer Co., has organized a company and will begin the manufacture of an automobile bumper which he recently patented. He hopes to make 10,000 bumpers this summer. The A. E. Palmer & Sons Co. will make the bumpers for him until he gets his own plant running.

Why Secretary Houston Opposes a Federal Highway Commission at This Time

Creation of New Machinery Would Cause More Confusion Than It Would Do Good in the Present Situation, Is View of Cabinet Officer---Opposing View Held by A. A. A. Leader

WASHINGTON, May 19.—In a statement issued to-day Secretary of Agriculture Houston tells why he opposes at this time the creation of a Federal Highway Commission. He believes that the injecting of new machinery into the highway situation at this time would cause confusion that would result in much harm. At present, the Secretary says, the Federal and state organizations are being dovetailed into an organization that will work out the best solution of the present problems. The statement says:

"Before expressing my views and my opinion as to whether it would be wise to take the Federal supervision of highways from the Department of Agriculture and place it under a Federal Highway Commission, it might be well for me to point out certain fundamental considerations which should be borne in mind when determining any sound policy of highway administration and development:

Five Fundamental Considerations

"(1) The roads in each section of the country are of varying degrees of importance in the service which they render or may render to the particular locality, to the State and to the nation as a whole.

"(2) This is a big country and the traffic conditions and needs vary greatly from section to section.

"(3) The State Highway Departments, being in immediate touch with local conditions, are best able to classify the roads properly on the basis of the economic purposes which they may serve.

"(4) The Federal government, under the present Bankhead Federal Aid Road Act, is co-operating in the improvement of the roads of greatest importance, the classification of which is fixed by the State Highway Department.

"(5) When this classification has been carefully made and by agreement between the highway departments of adjoining states, the roads of first importance generally meet at state boundaries, and therefore, become interstate highways of nation-wide utility. The Federal government, under the present law, is aiding the State Highway Departments in the classification of their roads on the basis of importance and needs, and Federal aid is rapidly being extended for their improvement."

The machinery provided by the Bankhead bills insures sufficient effective control of highway construction, stated Secretary Houston, and the Federal Bureau of Public Roads is already one of the largest and most effective organizations of its kind in the world and when co-operating with the forty-eight State Highway Departments is thoroughly capable of serving the public interest and there is no need for additional machinery. Each state, he said, has accepted the Federal aid act and is already co-operating with the Department of Agriculture, having appropriated large sums, passed laws and regulations which could not easily be changed, and perhaps would not be, to conform with the Federal Highway Commission plans and instead of asking for more or different legislation, he urges to proceed actively and vigorously with the construction of roads under existing arrangements.

"I have been unable to see the need for the creation of a separate Federal Highway Commission or the wisdom of substituting for the present co-operative program," said Secretary Houston, "a plan which would commit or limit the Federal government to the construction of two Federally owned and maintained trunk lines in each state of the Union. There was a bill introduced in the Senate of the United States on Feb. 13, 1919, embodying these suggestions. This proposed legislation provides for a Federal Highway Commission of five, each receiving a salary of $10,000 a year, whose duty, among other things, would be to establish, construct, and maintain a system of highways 'to comprise not less than two main trunk line roads in each state, and joining the National Highway System in the adjacent states and countries.' The Commission is given the power to select the trunk line roads to be constructed after having requested the State Highway Departments to recommend routes. The Federal Government is to assume the maintenance of these roads. The Commission is furthermore empowered to take over the work of all existing Federal agencies relating to highway transportation and '*to purchase, lease, rent, operate, and maintain such motor and other transportation facilities as it may deem necessary in performance of its duties under this Act.*'

"In July, 1916, the Bankhead Road Act was passed. It provided appropriations out of the Federal Treasury, to be matched by equal sums from the States, for the construction of roads, and provided further that no State should receive any of the money appropriated unless it had a highway department with adequate powers. The law placed the administration of the Act in the hands of the Secretary of Agriculture, in co-operation with the 48 State highway departments. It was enacted only a short time before we entered the European war and its operation was necessarily greatly interfered with by the disturbed conditions. There were also certain features of the law that made its smooth administration difficult. After the cessation of hostilities, with the approval of the President, I requested Congress to make a large additional appropriation to aid the States in highway construction and also to make certain amendments to the law, the necessity for which experience had demonstrated. Congress, through the Bankhead amendment to the Post Office Appropriation Bill, provided an additional appropriation of $209,000,000 and substantially made the amendments suggested.

No Limitation for State Roads

"Under existing legislation, there is no special obstacle, so far as I can see, to the construction, in the different States of the Union, of those roads which serve the greatest economic needs. In the first place, the definition of the kind of roads that can be constructed has been greatly broadened and, in the second place, the limitation on the Federal contribution for any one road has been increased from $10,000 to $20,000 a mile. Following this legislation, the regulations governing the administration of the Act and the standards for plans, specifications, and estimates have been modified and one of the most successful former State highway engineers in the country has been placed in immediate charge of the Federal Aid Road work.

"He has at his disposal a considerable staff of local and district engineer aids and no pains will be spared to provide any further Federal assistance that may be needed. The machinery provided by the Bankhead amendment includes not only the Federal Bureau of Public Roads, one of the largest and most effective organizations of its kind in the world, but also the 48 State highway departments, the two agencies working in close co-operation. It is also a part of the plan to have an advisory committee, composed of representatives of the State Highway Departments, selected by the American Association of State Highway Officials with due regard to geographic considerations, to work in intimate touch with the Federal Bureau, meeting with its officers at stated periods

and at such other times as may be necessary. This machinery, in effect, is an expert national commission intimately in touch through its various parts with all sections of the Union, having no other purpose than that of serving the public interest. It is difficult to see what need there can be for additional machinery.

"Very properly the Bankhead Act places on the highway authorities of the several States responsibility, in large measure, for selecting the roads to be constructed. Obviously, the local authorities are in a better position to judge what roads would serve the largest economic needs than any group of men sitting in Washington would be. It is the duty of the Federal Bureau, with its district engineers, to see that the provisions of the law are complied with. It is giving, and will continue to give, all possible assistance to the State authorities in all their technical problems, as well as in the planning of State systems and in the classification of roads. It has been the policy of the Department from the outset, in order to prevent haphazard action, to have the State highway authorities prepare and present tentative State systems of roads.

Rigid System Inadvisable

"It was apparent that a rigid system, not subject to modifications as conditions might require, would be inadvisable. Each State authority has worked out a system and, in general, it is being followed in the development of projects and the construction of roads. In a number of instances systems in general terms have been adopted by State legislatures. Of course, in formulating these systems, the engineers gave due regard to interstate connections, that is, to roads connecting the system of one State with that of another, and it is difficult to see why, as progress is made, the construction of through roads will not follow as a matter of course.

"It seems scarcely likely, in view of the fact that nearly $300,000,000 is now available out of the Federal Treasury, that the Congress, in the light of the financial situation, will make additional large appropriations; and it would be impossible, without creating many complications, to divert the existing appropriations from the purposes and plans already under way under the co-operative arrangements with the States. A considerable part of the available appropriations has already been formally tied up under agreements with State departments and contracts for large sums have been let. Additional large amounts are being pledged monthly. Every State has accepted the Federal Act and many of them have by law directed its agencies to co-operate with the Secretary of Agriculture.

"A number of the States have large sums available for co-operation, in many instances much in excess of what is necessary to meet the requirements of the Federal Act, and other States are preparing greatly to increase their appropriations. These State laws and arrangements cannot easily be changed and perhaps would not be. After the original act was passed, more than a year elapsed before many of the States were able to secure legislative action which would enable them to comply with the Federal law and to begin the construction of roads. With the passage of the amendment carrying a large additional appropriation, there arose a necessity for further legislative action in some of the States. It seems to me that, instead of asking for more or different legislation, we should now proceed actively and vigorously with the construction of roads under existing arrangements.

No Gain by Change

"I am convinced that nothing material would be gained by the proposed change. Much would be lost. As has been pointed out, many complications would be introduced. The creation of a Commission would entail unnecessary additional administrative expenditures and the Commission could not do anything that cannot now be done more effectively by the existing co-operative machinery. There would also be a radical change of policy. I do not think that the people of the States will be willing to substitute for the present policy of developing roads on the principle of serving the largest economic purposes that policy advocated by those whose interest is in two main or trunk line automobile roads in each State, nor do I think that they would be willing, even if it were legal or practicable, to have existing funds diverted from the present or contemplated projects, worked out with the aid of the State highway departments, solely to the construction of such roads.

"By far the largest service will be rendered, not only to farmers, but, in the long run, also to urban people, by following the principle of constructing roads of the greatest economic importance, selected after careful consideration by the State agencies having adequate knowledge and approved by the Federal Department. It seems to me clear also that, as the work proceeds, we shall have roads which will be equally serviceable not only to those interested immediately in long distance automobile travel and motor truck transportation, but also to those interested in getting their farm produce to the market in the easiest and the most effective manner and in the transportation of the mails. I have no prejudice against any sort of road except a bad road, or against any sort of construction except wasteful and unsubstantial construction. If traffic conditions require heavy construction, then I am in favor of it; and in any case, under the law, the construction must be substantial.

"The road construction movement is growing very rapidly. The Federal Aid Road Act has done much to promote it. It has stimulated financial aid and has caused many State legislatures to create central highway departments. Experience has brought about amendments to the law and helpful changes in administration. Comprehensive road programs have been inaugurated. They are being pushed vigorously. They will result, in a shorter time than most people imagine, not only in a network of good substantial roads in the various States of the Union, but also in the requisite interstate highways."

A. A. A. Leader Favors the Federal Commission

WASHINGTON, D. C., May 19—"That a commission, as contemplated by the Townsend-Bankhead bill, will be the method of administration adopted by Congress for building a National Highway System is indicated not only by public sentiment but by the weight of Government precedent," says Dr. H. M. Rowe, past president of the American Automobile Association and a member of the special committee of the A. A. A. Good Roads Board which will devote much time to Federal highway legislation.

"Highways should be considered in the same class of public activity as railways, waterways, merchant marine, the national banking system, and, in fact, any of the great distinctly national undertakings," continues Dr. Rowe. "It seems a self-evident proposition that the building of a national system of highways will form an enterprise of such magnitude and such complexity as to put it entirely beyond the sphere of a single bureau or other subdivision of an executive department and if, therefore, it be considered in the class of these greater national enterprises I have named, we should naturally expect to see the same kind of administrative machinery established for highways.

"By way of precedent, therefore, we may point out that the railroads while under government control are managed by a director-general who is not subject to the control of any Cabinet officer and that in the absence of government operation of railroads the Interstate Commerce Commission functions independently of executive departments. When we turn to the great shipbuilding and merchant marine industry, we find these are managed by the Shipping Board and the Emergency Fleet Corporation, both functioning apart from executive departments.

"There is no existing executive department which could legitimately take over the entire task of building a National Highway System. It might be contended that the Department of Agriculture should do the job because of the agricultual interests affected by highways, but immediately the counter-contention might be made that the War Department should build the system because of the military and national defense needs of the nation. The Post Office Department might very logically claim that its rural delivery and parcel post service should entitle it to control.

"The Department of the Interior, being almost entirely a public works department, might contend that a constructive engineering task should fall in its domain.

"As an outcome of these various contentions must come the realization that highways are of such an all-embracing and of such general importance as to make it impracticable to entrust the task as a minor undertaking to any single government department. A commission would consider the needs of all of the departments.

Indianapolis Picking Up on Production

INDIANAPOLIS, May 20—Local car production is on the increase, with the demand well exceeding the supply. The combined output at present is about 80 cars a day, with prospects of a considerable increase.

Pre-war production is being exceeded. The Nordyke & Marmon Co. has reached 18 cars per day, six more than its pre-war output. Its manufacturing facilities will be increased considerably when the new Liberty engine plant is devoted exclusively to passenger cars. Cole is running approximately 25 cars daily and plans to produce 5000 cars this year. Premier at present is turning out 10 cars daily. Its production has been delayed by material difficulties which are now understood to be overcome. Daily production at present is as follows: Cole, 25; Marmon, 18; National, 15; Stutz, 12; Premier, 10.

Studebaker Additions

SOUTH BEND, IND., May 20—Additions to the plant of the Studebaker Corp. in this city will occupy 61 acres of ground when completed and will contain between 3,000,000 and 4,000,000 sq. ft. of floor space. Twelve thousand employees will be required to operate the new plant. The capacity of the establishment will be 500 cars a day.

The power house will supply 8000 horsepower. The machine shop will be a one-story saw-tooth roof building 475 by 1125 ft. The large sub-assembly and stock building will also contain the administrative offices of the production department, besides toolrooms and the machinery maintenance department. This building is to be 192 by 1057 ft. Plans provide for a foundry, press steel stamping plant, treating and carbonizing plant, closed body plant, and the final assembly building.

American Auto Body Pays First Dividend

MILWAUKEE, WIS., May 20—A first dividend of 15 per cent has been paid to creditors of the American Auto Body Co., North Milwaukee, recently declared bankrupt. The assets were sold to E. J. Patterson for $7,750.

Officers of Franco-American Engineering Co.

DETROIT, May 17—The officers of the Franco-American Engineering Co. besides Georges Lepere, who is president, are: Vice-president and secretary, Herbert Hughes, and treasurer, S. L. De Pue.

Industry in Cleveland Increasing Forces

Employment Service Finds Most Other Lines Have Declined 30,000 Seeking Jobs

CLEVELAND, May 20—The United States Employment Service has obtained figures from 170 Cleveland manufacturers, which reveal that there are about 20,000 fewer workmen employed in Cleveland at present than the last day before the armistice was signed. In all plants from which returns were received 77,659 persons were employed. A few industries, notably the automotive industries, report more men employed now than ever before, but this increase is more than balanced by declines in other industries.

Estimate 30,000 Unemployed

The employment service estimates that the present unemployment in the city is 30,000, which includes about 6000 building trades workers. A figure of 30,000 is about 50 per cent more than what might be called normal unemployment. Data from the 170 plants showed 77,659 men at work May 5, against 100,193 at work in 155 plants early in November.

The plants were selected as a cross-section of industry as a whole, and include a few concerns which had been working almost entirely on war work. All the large Cleveland factories are included. The average number employed in each factory is placed at 457 men. The data are to be collected every week and will be forwarded to Washington. From it and similar data collected in every employment field the government expects to have before it an exact barometer of industrial conditions.

Automotive Plants Increase Employees

The Cleveland figures bring out the curious fact that the decline in numbers employed was only 12 per cent in the 35 largest factories in their lines, while the whole decline in numbers employed in the 170 factories is about 28 per cent.

The five largest Cleveland automotive plants were employing 9535 men in November. Last week they had 9,908 on their pay-rolls. Plants depending largely on the automobile parts business were employing nearly the same numbers. This also was true of railroad shops, although the men are working shorter hours.

Steel mills are operating only part time in some instances, and one or two small mills are shut down. Practically all the men are at work, however, although at shorter hours than before and sometimes only part time. The efforts of some of the companies to Americanize their plants has resulted in the wholesale discharge of unnaturalized foreigners, and these constitute a large part of the unemployed. In some plants, employees who stayed away from work to celebrate May day were discharged.

Whatever the employment situation may be, it is apparent that the returning soldiers and sailors are taken care of. The Y. M. C. A. has ten jobs for every soldier or sailor appearing at its employment office. These are mostly shop jobs and in most cases are open only to returned service men. Six of the largest factories have 1000 jobs open to such men. The revival of navigation is giving hundreds of ex-navy men jobs. The big marine companies are giving former navy men preference, because they are naturally better adapted to lake work than any other class of labor.

Working Conditions Service Created

WASHINGTON, May 16—The Department of Labor has organized a Working Conditions Service, including departments on industrial hygiene, research, education, standardization, safety engineering and general employment problems. The service will attempt to prevent sickness, accidents and labor disturbances and is developing a national information center on health, safety and labor in Washington. This information as gathered will be available to all industries.

Specialists will be sent upon request to various concerns requiring examination of the working conditions of plants. The industrial safety program will make examinations into engineering defects, unavoidable trade risks and those accidents caused by the human element. The employment division is collecting data on the source of labor supply, the organization of a centralized employment department, methods of employment, shop analysis, methods of "breaking in" men, promotion and transfer, turnover, absenteeism, restaurants and lunchrooms, housing, recreation, insurance and pensions.

Tractor Sales Climbing

DETROIT, May 19—Tractor sales are climbing rapidly, according to C. E. Sorensen, general manager of Henry Ford & Son, at Dearborn, Mich. Mr. Sorensen reports splendid sales from Iowa, Nebraska, Kansas and throughout the entire wheat district; also a gaining tractor market in Texas.

Tractor sales have been distributed throughout all the season due to the unusual winter conditions. In Iowa farmers were plowing practically all winter. One retarding feature of tractor sales is the inability of farmers to secure good prices for their horses. The customary reason a farmer gives for delaying purchasing a tractor is that he cannot get enough money for his horses.

State Roads to Aid Federal Highways

WASHINGTON, May 19—A committee of state highway officials have been appointed to co-operate with the Federal bureau of public roads to carry out the provisions of the Federal Aid Road Act. A. R. Hirst, president of the American

Association of State Highway Officials, has selected the following members for the committee: George P. Coleman, state highway commissioner of Virginia; S. E. Bradt, state superintendent of highways of Illinois; Charles J. Bennett, state highway commissioner of Connecticut; W. S. Keller, state highway engineer of Alabama, and Ira R. Browning, state road engineer of Utah.

It also was announced that the Secretary of Agriculture up to May 1 had approved 1057 project statements for Federal aid roads, involving the improvement of 10,580 miles of highways at an estimated cost of $92,933,000.

—

Dealers' Association Adds Commercial Division

ST. LOUIS, May 19—A commercial division of the National Automobile Dealers' Association has been formed to handle all problems that arise solely in the truck sales field. H. N. Cartinour of the Cartinour-Bowman Co., Indianapolis, is commissioner of the new division.

—

Import Restrictions Send English Car Prices Up

LONDON, ENGLAND, May 1—The direct result of the exclusion of automobile importation continues to make itself felt in the increasing price of cars. Thus the new Austin 20, which was listed at $2,000, was recently increased to $2,500. A few other examples of how prices are going up are: 12-hp. Rover, which before the war was very popular and listed at $1,750, is now selling without a single alteration at $3,500. The 11-hp. Arrol Johnston, which previous to the war sold at $1,875, is now listed at $3,500.

—

National Highway Industries Assn. Commended by M. A. M. A.

WASHINGTON, May 16—The Highway Industries Association has received a special communication from the Motor and Accessory Manufacturers' Association commending it and approving its work on the plan for a Federal Highway Council.

—

Additional Road Construction Planned

WASHINGTON, May 16—The U. S. Forest Service plans to construct 1643 miles of roads during 1919 at an expenditure of $12,000,000.

—

Bond Issues for Road Construction

WASHINGTON, May 17—Bond issues planned or approved in 26 states for highway construction total $823,300,000. Of this, $177,800,000 have already been authorized in 7 states, $411,500,000 have been referred by legislatures in 12 states to the vote of the people, $135,000,000 are being considered in four states, and three states have voted against measures totaling $85,000,000. The issues ratified include Oregon, $10,000,000; Nevada, $1,000,000; Utah, $4,000,000; Wyoming, $2,800,000; Michigan, $50,000,000; Illinois, $60,000,000, and Pennsylvania, $50,000,000.

Bond issues which will be considered shortly include Alabama, $25,000,000; Georgia, $60,000,000; Florida, $10,000,000, and Virginia, $50,000,000. People will vote on highway bond issues in the following states: California, $40,000,000; Washington, $30,000,000; Oregon, $2,500,000; Idaho, $2,000,000; Colorado, $5,000,000; New Mexico, $2,000,000; Oklahoma, $50,000,000; Texas, $75,000,000; Minnesota, $75,000,000; West Virginia, $40,000,000; Missouri, $60,000,000; Maine, $10,000,000, and New York, $20,000,000.

Great Britain Removes More Import Restrictions

WASHINGTON, May 19—Pressure regulators, lubricators, grease cups, pump and engine governors, pressure and vacuum gages, copper wire, drop-forged steel and oil cans may now be imported into Great Britain without individual licenses, according to an announcement made by the War Trade Board, as all restrictions on these imports have been removed.

—

Oil Restrictions Removed

WASHINGTON, May 19—All rules and regulations governing the production, manufacture, distribution or trans-

portation of oil in its various forms, including gasoline, and of natural gas were removed yesterday by an order of Fuel Administrator Garfield, which follows:

"The fuel administrator hereby orders and directs that all rules, regulations or orders heretofore issued or promulgated by or under authority of said United States fuel administrator governing licenses engaged in the business of importing, manufacturing, distributing and transporting crude oil, fuel oil, gas oil, kerosene, gasoline and natural gas or regulating the production, sale, distribution or use thereof and all amendments and modifications of said rules and regulations and orders be, and the same hereby are, vacated and set aside as of May 15, 1919."

Government Vehicles for Public Sale

After Disposal to Government Departments About 1000 Expected to Be Left for Public

WASHINGTON, May 20—The major portion of all surplus motor trucks and cars purchased by the army will be transferred to the various Government departments. A comparatively small supply of used passenger and commercial cars of miscellaneous makes, not adapted for governmental use, will be sold at public auctions held at various military posts and camps beginning June 1.

More than 10,000 trucks, cars, ambulances and motorcycles have already been transferred by the War Department to other Government bureaus. Deliveries have been made to the Post Office Department and the Public Health Service. Of these trucks 5565 have been turned over to the Department of Agriculture and within a few days shipments of this equipment will be made by the Motor Transport Corps to Road Commissioners of the states to which allotments have been made by the Bureau of Public Roads of the Department of Agriculture.

As fast as the several states place the present consignments in operation, the Director of Sales will transfer additional trucks and road building machinery. The further needs of the Department of Agriculture, the Post Office Department and the other Government departments are expected to absorb practically the entire surplus of motor vehicles acquired for military purposes.

The motor equipment which is to be disposed of at public auction will be announced through advertisements in the press local to the communities in which the auctions will be held. The number which will be sold at auction will be very limited, and it is anticipated will number 1000. Detailed figures are not now available as it is possible that the Government bureaus will absorb all of the surplus.

—

Aircraft for Forest Fires

WASHINGTON, May 20—Two routes have been established for airplane patrols for discovery of forest fires. These start and end at the March Field, 12 miles southeast of Riverside, Cal. Fires discovered will be reported by parachute messages, by special landings or by return to the base. The service will start on June 1.

—

Four Permanent French Air Mail Routes

PARIS, May 10—Four aerial mail routes are about to be put on a permanent basis by the French Government. These are: Paris to Havre, Paris to Lille, Paris to London, and Paris to Brussels. Three of these lines are just ready for operation.

The Paris-Lille line has been taken over by the Breguet Co. and the Paris-London line will probably be given to a Franco-British concern. These aerial lines will not be operated direct by the French Government, but in each case by a contracting company.

In addition to the above, it is proposed to establish an aerial mail route from Paris to Nice. This will be run in two stages: the first from Paris to Lyons with stopping stations at Auxerre and Dijon, and a second stage from Lyons to Nice.

—

Moore to Double Output

DANVILLE, ILL., May 20—The Moore Motor Vehicle Co. will double its working force during June. It is claimed that by June 25 the output of the plant will reach 125 cars a day. At present the output is 62 daily.

Bureau of Enemy Trade Takes Over War Intelligence

WASHINGTON, May 20—The Bureau of War Trade Intelligence has been merged with the Bureau of Enemy Trade, and such work of the Bureau of War Trade Intelligence as is still being carried on will be conducted by the Bureau of Enemy Trade.

—

Markets for Motorcycles and Cars

WASHINGTON, May 19—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has received information that there are excellent markets for American motorcycles and automobiles at Antwerp, Holland, and for small and medium sizes of tractors in South Africa. There is a market for power shearers in South Africa. If manufacturers will send literature on tractors to Commercial Agent R. A. Lundquist, Durban, Natal, South Africa, he will distribute them.

Men of the Industry

Changes in Personnel and Position

Stratford Goes West to Associated Oil Co.

NEW YORK, May 16—C. W. Stratford, lubricating oil engineer of New York, has been appointed general consultant of the Associated Oil Co., San Francisco, and has left for his new position. The Associated Oil Co. heretofore has confined its work to topping only in the oil industry, but is now taking up the manufacture of lubricating oils. It is in connection with this work that Mr. Stratford has been engaged. He was formerly connected with the Tidewater Oil Co. and recently has been organizing an oil-testing laboratory at the Bureau of Standards in Washington.

—

W. K. Swigert, who has been superintendent of the Liberty airplane engine division of the Nordyke & Marmon Co., Indianapolis, since its inception a year and a half ago, will, after June 1, be in charge of development work of the Dort Motor Co., Flint.

—

A. W. Frehse has been appointed sales engineer of the wheel division of the Detroit Pressed Steel Co. Formerly he was in charge of design under the chief engineer of the Thomas B. Jeffery Co. Later he was assistant chief engineer of the Jordan Motor Car Co. He has recently been in Government service as consulting engineer.

—

S. H. Houser, formerly sales manager of the Standley Skid Chain Co., Boone, Ia., has joined the sales force of the Gray-Heath Co., Chicago.

—

Earl B. Wilson has been appointed director of sales of the Buick Motor Co. factory at Flint. Previously to that he was in charge of the Buick Chicago branch, and later was transferred to the Memphis branch. More recently he was manager of the Philadelphia branch of the Buick company.

—

A. E. Mason, who has been connected with the Chalmers Motor Co. as superintendent of sales in Wyoming and Colorado territory, is now connected with the Western Motor Car Co., Omaha, Neb.

—

C. V. Lyons has been appointed eastern sales manager of the Nelson Truck Co., Saginaw, Mich. He will have charge of the distribution of the John Simmons Co., New York City.

—

Williams Beckman has resigned as experimental engineer with the Duesenberg Motors Corp., Elizabeth, N. J., to become engineer and eastern representative for the Beckman Metal Products Co., Cleveland.

—

R. H. Welles, former general manager of the Badger Brass Co., Kenosha, Wis., will be representative of Charles S. Monson, Detroit, and will have his office in Chicago.

Cadillac Sales Manager Resigns

DETROIT, May 20—S. C. Howard, sales manager of the Cadillac Motor Car Co., has resigned to take effect June 16. He will stay in the automotive business, but says he hopes to work for himself. It is rumored that he will be associated with D. McCall White in a new venture.

Mr. Howard joined the Cadillac company in 1909, coming from the National Cash Register Co., Dayton. In 1910 he was made assistant sales manager and in 1912 was promoted to sales manager.

—

Blaine McGrath, former advertising manager of the Republic Motor Truck Co., has entered the sales department of the company. He has established headquarters at Birmingham and will cover Alabama and parts of Mississippi, Texas and Florida.

—

Calvert Townley, assistant to the president of the Westinghouse Electric & Mfg. Co., was elected president of the American Institute of Electrical Engineers at the annual business meeting of the Institute held Friday.

—

Major B. Hawxhurst, formerly representative of the Westinghouse Co. in Detroit, is now president and general manager of the Automotive Products Co. of Detroit and Chicago.

—

F. W. Ramey, recently released as a lieutenant from military service, has been placed in charge of sales at the Cotta Transmission Co., Rockford, Ill.

—

Karl A. Eichhorn, formerly of the Packard Motor Car Co., is manager of the new offices opened in Detroit by James Barr & Co., public accountants, New York City.

—

Edwin A. Godley, formerly connected with the eastern division of the Overland Motor Car Co. and with the Olds Motor Works, has been made general office manager of the Republic Motor Truck Co., Inc., Alma, Mich.

—

Frederick A. Crooks has been elected president of the Biddle Motor Sales Corp. Associated with him is W. H. Howill.

—

C. C. Thomas, sales engineer for the Denby Motor Truck C., Detroit, has resigned and joined the force of the Field Mfg. Co., Owosso, Mich.

—

J. C. Barlow, founder and chief stockholder of the Streator Motor Car Co., Streator, Ill., is dead.

Homer Ferguson Heads U. S. Commerce Chamber

WASHINGTON, May 16—Homer L. Ferguson, of Newport News, Va., president and general manager of the Newport News Shipbuilding & Dry Dock Co., has been elected president of the Chamber of Commerce of the United States. This annoucement was made yesterday at the offices of the chamber here as the result of a mail vote of the organization's board of directors.

Mr. Ferguson succeeds Harry A. Wheeler of Chicago as president. Mr. Wheeler declined re-election after serving two separate terms. Mr. Ferguson was nominated immediately after the the chamber concluded its annual meeting at St. Louis this month, and was unopposed.

Other officers elected by the board were: Vice-president, Eastern district, A. C. Bedford, New York; North central district, Joseph H. De Frees, Chicago; South central district, Thomas F. Gailor, bishop of Tennessee, and Western district to be filled later. Honorary vice-presidents are Harry A. Wheeler, Chicago; John H. Fahey, Boston; A. B. Farquhar, York, Pa.; Charles Nagel, St. Louis, and R. G. Rhett, Charleston, S. C. The executive committee is composed of: Joseph H. De Frees, chairman; Max W. Babb, Milwaukee; A. C. Bedford, W. L. Clause, Pittsburgh; L. S. Gillette, Minneapolis; P. H. Gadsden, Charleston, S. C.; Frederick J. Koster, San Francisco; James R. MacColl, Pawtucket, R. I.; Charles A. Otis, Cleveland; Lewis E. Pierson, New York, and M. J. Saunders, New Orleans.

—

Ungar Vice-President of F. R. Blair & Co., Inc.

NEW YORK, May 19—G. A. Ungar, who for several years has been engineering and technical director of the SKF Ball Bearing Co., has resigned to become vice-president of F. R. Blair & Co., Inc., of which company he has been a director since its organization. It was incorrectly reported in the May 8 issue of AUTOMOTIVE INDUSTRIES that Mr. Ungar would become vice-president of the SKF company. In his new position Mr. Ungar will have charge of the sale of Flexite specialties, of several of which he is the patentee.

—

Wichita Now Mid-West Tractor

WICHITA, KAN., May 19—The Wichita Tractor Co. has changed the name of its tractor from Wichita to Mid-West, but has made no change in its firm name.

—

Brotherton-Brown New Advertising Concern

Cliff Knoble, formerly advertising manager of the Liberty Motor Car Co., and Norton Brotherton, formerly of Seelye - Brotherton - Brown, advertising agents, have formed a new agency known as the Brotherton-Brown Co., with offices in Detroit.

Jordan Increasing Facilities 150 Per Cent

CLEVELAND, May 15—The Jordan Motor Car Co. is putting up additional buildings costing $175,000, designed to increase capacity 150 per cent. Five units are to be constructed, with other necessary accessories. There will be a new 2-story office building, 250 x 100 ft.; an assembly room, 100 x 300 ft.; power plant, 40 x 60 ft.; a japanning building, 50 x 100 ft., and a motor testing building, 30 x 90 ft. The present main building will be completely remodeled. There will also be built additional railroad sidings and a concrete loading platform, 600 ft. long. Work is scheduled to start immediately.

Liberty Building New Factory

DETROIT, May 19—The Liberty Motor Car Co. will have a new factory adjacent to the Hudson Motor Car Co., the Continental Motors Co., Wadsworth Mfg. Co., Maxwell-Chalmers and a number of other automotive plants. With the new factory the company hopes to double its present production. Its present plant, the old R. C. H. corporation group of buildings, is proving unequal to present manufacturing demands.

Perfection Heater Division of Standard Parts Sold

CLEVELAND, May 16—The Perfection Heater & Manufacturing Co. has acquired the entire organization of the Perfection heater division of the Standard Parts Co. The new company, which is capitalized for $300,000, has leased a building on Carnegie Avenue, near East Sixty-fifth Street, and increased production to 1000 heaters per day. W. A. C. Smith is president, and other officers are: Vice-president and general manager, C. S. Pelton, connected for seven years with the Perfection spring and the Perfection heater divisions of the Standard Parts Co.; secretary and treasurer, F. D. Kellogg. E. L. Jones, for a number of years with the Remy Electric Co. and the Standard Parts Co., will be special factory representative. L. H. Peck, formerly machine tool designer for the Foote-Burt Co. and recently released from aviation service, has charge of engineering and production.

Wheeler Radiator & Mfg. Co. Organized

CLEVELAND, May 19—The Wheeler Radiator & Mfg. Co., organized with an authorized capital of $2,000,000, will manufacture radiators for engines. W. H. Ritter is president, and will be in charge of sales and production. G. E. Wheeler, vice-president, will have charge of manufacture, and F. R. Kissling will be superintendent. The new firm is composed principally of members of English & Mersick Co., New Haven, Conn. A small factory will be erected on 1½ acres of ground on Collamer Avenue. New buildings planned will have 100,000 sq. ft. of manufacturing space.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

General Motors to Produce Half Million Vehicles Next Year

NEW YORK, May 16—The estimated output of motor vehicles of all classes by the General Motors Corp., from July 1, 1919, to June 30, 1920, is placed at 577,000. Of this total, passenger cars account for 512,000, trucks for 40,000 and tractors for 25,000. In addition, the corporation's output of farm implements is figured at 75,000. In its 41 plants General Motors employs 49,000 persons.

The General Motors company's total volume of sales for 1918, according to a booklet issued by the company, was $326,044,755, which was exceeded only by the U. S. Steel Corp., Swift & Co., Armour & Co., Bethlehem Steel Corp., Wilson & Co., and the du Pont company. Earnings on this volume, before taxes, amounted to $45,541,726. Net quick assets are shown as $150,390,492, of which more than $59,000,000 is in cash and Liberty Bonds.

Briscoe's New Car Ready

DETROIT, May 16—The new passenger car which Benjamin Briscoe and his assistant, Rodolphe Stahl, are designing for the Bellanger Freres Co., Paris, France, will be on the road in a few days. It is made entirely of American parts, most of which will be shipped to France if they cannot be manufactured at the plant of the French company.

Acason 1½-Ton Model

DETROIT, May 19—The Acason Motor Truck Co. has completed a 1½-ton model, thus completing the line from 1 to 10-ton capacities. The new model has a Waukesha engine, Timken worm drive axle, Blood Bros. universal joints, Detroit Steel Products springs, etc., and will be equipped with either 35 x 5 front and 38 x 7 rear pneumatic cord tires or 36 x 4 front and 36 x 6 rear solid tires. It will have left hand drive.

Michigan Crankshaft Improvements

LANSING, May 15—The General Motors Corp., which recently acquired the Michigan Crankshaft properties here, is equipping, enlarging and generally improving the new property. The old shops are being reroofed and painted. It is planned to triple the capacity of the former grinding plant by new equipment and enlarged floor space. A new administration building will be erected.

New Plant for Maibohm Motors

SANDUSKY, OHIO, May 20—The Maibohm Motors Co., moving here from Racine, Wis., where its plant was destroyed by fire, will occupy a new factory having 75,000 sq. ft. of floor space. The plant will be 620 x 120 ft., located on a 15-acre site. It will be of one story, sawtooth design and modern fireproof, day-light construction. It will have a capacity of 50 machines daily.

Packard Establishes Experimental Flying Field

DETROIT, May 17—The Packard Motor Car Co. has acquired a tract of land between this city and Mt. Clemens for use as a private experimental flying field in the development of its aviation program. The company will begin immediately to grade, tile and seed the new field and will erect buildings as they are needed. It should be ready for operation by midsummer.

Extra Charge for Canadian Ford Electrical Equipment

DETROIT, May 16—Canadian Ford touring cars and roadsters will be supplied with starting and lighting devices as optional equipment at an extra charge after June 1. All Canadian closed models now have the starters as part of standard equipment.

Blood & Co. to Handle Motor Exports

New YORK, May 19—W. D. Blood & Co., Inc., has recently been incorporated to handle American manufactures in foreign fields, especially automotive and hardware manufactures. W. D. Blood is president in charge of sales. He was manager of the export department of the Hendee Mfg. Co. for 7 years. John C. Gallagher is secretary and treasurer. He will be in charge of the main office at 44 Whitehall Street.

The company will have permanent representation in the South American countries. At the present time it is acting for the following concerns: Metz Corp., Waltham, Mass.; Corbin Screw Corp., New Britain, Conn.; Hawthorne Co., Bridgeport, Conn.; Witherbee Igniter Co., Springfield, Mass.; Witherbee Storage Battery Co., New York City; L. F. Benton Co., Vergennes, Vt.

Two Companies Bought by Bull Tractor-Madison Motors

ANDERSON, IND., May 19—The Bull Tractor-Madison Motors Corp. has acquired the factories and business of the Bull Tractor Co., Minneapolis, and the Madison Motor Car Co. The new company will manufacture the Bull tractor and the Madison motor car.

New Factory for Turnsted

DETROIT, May 16—Work is about completed on the new plant of the Turnsted Mfg. Co., a subsidiary of the Fisher Body Corp., and the company is preparing to move into its new quarters. The plant has a floor space of 100,000 sq. ft.

Air Mail Service Profitable in First Year of Operation

(*Continued from page* 1106)

a plane having a top speed of 75 or 80 miles against a surface wind of 40 miles or more an hour. The two types of planes in the Aerial Mail Service of this speed are the Standard JR1 mail plane, having a wing spread of 31 ft. 4 in., and the Curtiss JN-4-H, having a wing spread of 43 ft. 7⅜ in. Each type of plane is equipped with a 150-hp. motor. The motor of this strength has not enough reserve power to combat the disturbed air conditions at the surface in a wind of more than 40 m.p.h., especially so if the wind comes in descending columns or gusts. Under these conditions it is possible to make headway only with a Liberty engine, which has plenty of reserve power.

A plane equipped with a 150-hp. motor, if it succeeds in breaking through the surface wind, can make only slow and laborious headway against a full or a quartering head wind of about 40 miles. There have been many instances where the planes equipped with 150-hp. motors have been held down to a speed of between 30 and 37 m.p.h.; also many instances where a 100-m.p.h. plane equipped with Liberty motor has been held to between 55 and 60 m.p.h. of speed. A few windstorm conditions were encountered on trips where the planes at the height of the gusts were actually carried backwards.

Two Periods of Remarkable Gales

There were two periods of remarkable gales encountered during the year. One was on December 6, 1918, on the Washington-Philadelphia flight. On that day the wind reached a maximum of 50 m.p.h. at College Park, Md., during the flying hours. It blew the plane around like a leaf and put down the first small plane that attempted to get out, damaging the machine. A second plane with 150-hp. engine got through the disturbed conditions, and at an altitude of 500 ft., above which it could not rise. The wind was so powerful that it took in excess of one hour for the plane to travel from College Park to Laurel, Md., a distance of less than 12 miles.

On the same day the plane leaving Philadelphia for Washington encountered a 60-mile wind, against which it battled for 2 hr. and 41 min., in which time it covered only 113 miles.

The other gale period began on the afternoon of March 27, overtaking two of the mail flyers in the air. It helped one along on his route, but forced the other to land, the maximum velocity of the wind being 45 m.p.h. This gale grew in intensity and blew unabated on March 28 and 29, and on these two days the most remarkable flight in all history of aviation was undertaken in the face of the storm. At College Park an aviator made three attempts to take off in the storm, feeling that once above the disturbed surface conditions he could continue on his way. The highest altitude with the 150-hp. motor he could reach was 140 feet, at which height, as in the case of the other two attempts, descending currents of air pressed his machine down to the ground with such force as to injure the landing gear. The maximum ground velocity at College Park at the time the attempts were made was 46 m.p.h., but the air currents were in a great state of disturbance. The weather observer's report for Washington for this day is as follows:

"Heavy northwest gale continued throughout the day and night. Some houses were unroofed, according to press reports, and many trees were uprooted. Wire communication was interfered with. A two-masted schooner was reported sunk and crew lost 70 miles below Washington. The wind at times attained an extreme velocity of 55 miles."

At Belmont Field, Long Island, attempts were made to get away with the mail in a small motor plane in a surface wind of 54 m.p.h. The attempts with the small planes were made at the suggestion of the pilots, who believed an airplane with small wing spread stood a better chance in the gale than one of a larger wing spread, even though equipped with greater power. At Philadelphia the reserve air-mail pilot, J. N. Miller, who was a former naval flyer, essayed the trip with a Curtiss R-4 plane of 48 ft. 4⅛ in. wing spread and powered with a 400-hp. Liberty engine. He rose against a surface of wind of 43 m.p.h. and flew by compass into a snow storm then raging over New York City, and picked up a land mark in the Woolworth Tower, 300 feet above its spire, and then directed his course through the gale and storm, which the Weather Bureau reports at that hour as having a maximum velocity on the ground at New York of 68 m.p.h. The velocity of the wind was 15 per cent greater at the altitude at which this pilot was flying than on the ground. Telegraphic reports from Belmont Field at the time reported visibility at 50 ft. on the field, and the flyer, not being able to pick it up, landed at Great Neck, Long Island, a short distance beyond the aerial mail field. He set down his plane with damage to landing gear. The Weather Bureau reported on the gale over New York that day as follows:

"Snow squalls at times were heavy, obstructing the view in the harbor and interfering with traffic. Maximum wind velocity was 92 m.p.h., a record surpassed only once at this station—recorded at 9.25 p. m. The average velocity for the last 12 hr. was 62 miles, and for the last 6 hr. was 68 miles. According to the city press, the loss of life and damage to property was considerable."

At 3.25 p. m., at which time the air-mail pilot was struggling with the gale over New York City, the maximum velocity of the wind recorded by the Weather Bureau at New York was 68 m.p.h. on the ground. The performance of this flight for courage and successful handling of an airplane has never been surpassed, perhaps never equalled.

NOTE.—This pilot returned to Philadelphia by train that night and the following day he repeated the performance under almost as bad conditions.

On March 29, at College Park, the air-mail pilot again undertook three times to get under way in a small plane with 150-hp. engine. The larger plane with the Liberty engine had been rendered unserviceable by the collapse of a tent in the storm. The highest elevation reached on that day was 150 ft. In each of the three attempts the wind forced the plane almost vertically to the ground, setting it on its nose each time, resulting in broken propellers. The gale was blowing in gusts at a maximum of between 38 and 40 m.p.h. At Philadelphia the same air pilot who had flown the day before with the Curtiss R-4 and the Liberty engine, took off in a 42-mile gale with a DH-4 airplane run by a 400-hp. Liberty engine. He had better visibility on his trip, but he flew through a gale that was blowing at a maximum of 80 m.p.h. when he successfully landed with the mail at Belmont Park at 4.45 p. m.

Weather Bureau's report on wind velocity at New York City during the hours of operating the aerial mail follows:

Miles Per Hour.

	Noon to 1 P.M.	1 to 2 P.M.	2 to 3 P.M.	3 to 4 P.M.	4 to 5 P.M.
March 28	54	49	67	68	78
March 29	75	77	78	77	80

One of the first studies which were taken up by the Aerial Mail Service was to determine whether visibility is absolutely necessary to commercial flying by airplane. Assuming that forced landings have been eliminated, except under the rarest circumstances, through multiple motors accessible for repair in the air, the question then resolves itself to this: Is visibility necessary to landing on a prepared aviation field?

The first step necessary was the refinement of the existing radio direction finders to such a point as to eliminate the liability of 3 to 5 per cent of error and make absolutely certain the bringing of the ship directly to or over the field. This has been successfully worked out by the Navy Department on an aerial-mail testing plane.

The second problem was of guiding the mail plane to the center of the plot for landing. This problem has been solved by the Bureau of Standards of the Department of Commerce

in experiments conducted on the aerial-mail testing ship in connection with radio directional compass. At this time the device of the Bureau of Standards is entirely effective up to an altitude of 1,500 feet, and the refinements upon which the Bureau is at work should give it an altitude of another thousand or more feet, by means of this device the aviator circling around the field and coming down with the head of the machine always to the center of the field for the purpose of making a landing. At present a visibility on the ground of between 20 and 50 ft. vertical is necessary to enable him to gage when to set the plane down. Aeronautical engineers are working on a device for the automatic landing of a mechanically flown airplane. Such a device, or any device that will give altitude without reference to the barograph, should solve this problem. The condition of absolute invisibility requiring such a device would rarely arise, and exist only in the most blinding snowstorm, down-pour of rain, or impenetrable ground fog.

A year's flying of the aerial mail with all types and temperaments of aviators establishes the fact that 200 ft. visibility from the ground is the limit of practical flying, although a number of runs were made with the mail between New York and Washington in which a part of the trip was flown at the low elevation of 50 feet. The objection of aviators to flying above a ground fog, rain, snow or clouds with single-motor planes is due to the possibility of the motor stopping over a village or city, or bad ground, with the visibility of such a short radius that it would be impossible after gliding through the cloud or fog strata to pick a safe spot to land, whereas, if they fly just on the lower edge of the thick strata with the land constantly before them, they are in a position to skirt around the edges of cities, towns, timber, or other terrain for landing. It is generally accepted that with two or more motors the flights will be made above the clouds or fogs or rain banks, certainly as long as enough motors are running to hold an altitude. It is also clear that in a twin-motor plane, should one motor die, although the other motor is capable of carrying the plane forward, the pilot would come down below the area of invisibility and fly low as in the case of a single-motor plane.

During the year of operations a very careful record has been kept of the mechanical causes of forced landings. These have been entirely connected with the motor. There have been a total of 37 forced landings due to motor trouble, which is one forced landing for every 3460 miles flown.

Of the motor troubles sufficient to bring down a mail plane six have been due to ignition trouble, five of the six resulting from magneto disturbance, most frequently the shearing of a shaft. Disarrangement of the distributor and the failure of a generator for a Liberty engine were responsible for the other two forced landings chargeable to ignition. Work has begun in installing duplicate ignition systems for each engine, which will largely obviate forced landings from this source.

Leaking radiators or water lines are responsible for seven forced landings. It is believed that trouble from this source will be minimized by the installation of a radiator in the wing now fastened between the propeller and the engine in a position where it catches the vibrations of both the propeller and the engine.

Two forced landings resulted from valve trouble on Hispano-Suiza motors, the valves of these engines being an inherent weakness of the motor. This is a serious problem, and the Bureau of Standards has undertaken an investigation of methods to overcome it.

Failure of the gas pressure resulted in one forced landing, and this is easily remedied by the installation of an auxiliary gas tank on each plane.

Two forced landings resulted from carbureter trouble, the overcoming of which is now being studied.

There have been eight forced landings due to spark-plug fouling. This trouble can arise from several causes. It most frequently results from idling the engine in the preliminary warming-up stage before a flight. The Aerial Mail Service has urged spark-plug inventors to perfect this mechanism, and as the result of the assistance rendered one inventor has finally developed a spark plug which gives promise of entirely eliminating fouling. A set of these plugs in one bank of the low-compression Liberty engine operated 25 hr. in a test ship without being withdrawn from the cylinder for the purpose of cleaning. The plugs were then withdrawn and placed in service and have functioned perfectly. An order has been placed for this type of plugs for high compression as well as low compression Liberty and Hispano-Suiza motors.

A study of the motor troubles causing forced landings points irresistibly to the multiple engine as a solution. A multiple-power plane must be of such character that with half the power gone the remaining power will carry the airplane to its destination. Thus, in case of two motors, one motor should enable the pilot to continue his trip though at greatly reduced speed. In a three-motored plane it should be necessary to lose a second engine before a forced landing has to be made. In the specially constructed mail-carrying planes which the Department has outlined in bids to be opened on June 2, a form of construction is called for that will enable a mechanic to make important minor repairs in flight. Under these conditions it will be possible with a multiple motor to insure maintenance in the air until the objective point or terminus is reached.

OTTO PRAEGER,
Second Assistant Postmaster General.

Calendar

SHOWS

May 15-June 1—Venezuela. National Exhibit of Venezuela.
*Oct. 15—Paris. Grand Palais, International Automobile Mfrs. Congress.
Nov. 7-15—London. Olympia Motor Car Exhibition—Society of Motor Mfrs. and Trades.
December — Brussels. International Automobile Mfrs. Congress.
January—New York. International Automobile Mfrs. Congress.
February — Chicago. International Automobile Mfrs. Congress.
Feb. 23-Mar. 6 — Birmingham, Eng. British Industries Fair.

TRACTOR SHOWS

May 30—College Park, Md. — Power cultivator Demonstration, Maryland State Dept. of Agriculture.
June 8-14—Denver, Col. Sectional Tractor Demonstrations, Denver Tractor Club.
July 14—Wichita, Kan. Automotive Committee of National Implement Assn.
Aug. 18-22—Aberdeen, S. D. Sectional Tractor Demonstrations.
October—Ottawa, Ont., Can. Interprovincial Plowing Match and Tractor Demonstration.

CONTESTS

May 23—San Joaquin, Cal.—Grade 2 non-stock cars, reliability contest, San Joaquin Auto Trade Association.
May 30—Atlantic City, N. J.—Airplane races—Aeronautic Convention.
May 30-31—Richmond Va.—2-Day Dirt Track Meet, Virginia State Fair Grounds Track.

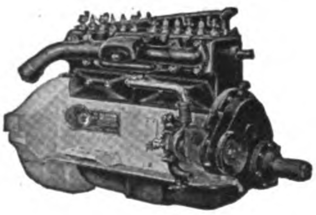
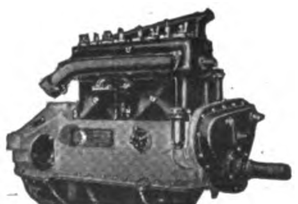
His Strongest Selling Point is the Red Seal Continental Motor



America's Standard Passenger Car Motor. Look for the Red Seal Nameplate.



America's Standard Truck Motor. Look for the Red Seal Nameplate.

The argument that most often clinches the sale of an automobile or truck is the Red Seal Continental Motor.

For there is hardly a man who is not familiar with the record of *past performance*—the infallible test of motor worth—which has distinguished this motor for well over a decade.

On hundreds of thousands of automobiles and trucks, under every conceivable condition of service the Red Seal Continental Motor has *proved* its 100% dependability. In the supertasks of war, in the vigorous tasks of peace, it has stood the test of service.

Today upwards of 15,000 dealers have signified their belief in the Red Seal Continental Motor by entrusting their business prosperity to Continental-equipped cars. And their choice is the Continental because of its proved record for power, for speed, for economy, for reliability.

Today more than 160 successful manufacturers of automobiles and trucks equip their output with Red Seal Continental Motors. The judgment of these manufacturers is vindicated by tens of thousands of owners who will have no other motor.

Look for the Red Seal on the motor in the car or truck you buy—and *be sure.*

Destruction of the Belgian Industry

By German Military and Civilians

Chiefly for Commercial Advantage

After Army Needs for Machinery and Material Had Been Met, the Work of Removal and Scrapping Was Continued with Object of Destroying Export Competition

By W. F. Bradley

> MR. BRADLEY, special European correspondent of AUTOMOTIVE INDUSTRIES, went to Belgium to investigate industrial conditions there especially for this paper. He was accorded special privileges by Government officials and owners of the various plants.
> —EDITOR.

BRUSSELS, May 1.—Germany robbed the Belgian Automobile factories of machinery, tools, materials and cars to the value of $10,000,000. This is a moderate estimate based on pre-war values. If present values were considered this figure would have to be increased by no less than 50 per cent. In arriving at this figure no account has been taken of the prejudice caused by the loss of business and unproductive capital during the four and a half years' occupation by the German armies.

Not a single Belgian automobile factory was destroyed or damaged by what may be termed direct warfare. The factories were at Brussels, Liége, Antwerp and in the Charleroi districts and were passed so rapidly by the German advance of August, 1914, that they were soon far inside the German lines and consequently never were within the range of the artillery. Notwithstanding the fact that they were outside the fighting zone, the Belgian automobile factories are ruined. The buildings stand, as in 1914, and to a casual observer appear to be undamaged. But a look inside shows that they have been stripped naked.

In any country at war it is expected that destruction will be found. When the security of a nation is at stake, the home forces may be under the necessity of destroying property to the same extent as the enemy. This article, however, does not relate to necessities of war but to a deliberately organized, and unfortunately successful, attempt to destroy an industry in order to remove a competitor.

The Belgian automobile industry was not big. In 1914 it consisted of fifteen firms, the most important of which employed 3000 men; the total production was 8000 cars per annum.

The truck industry was non-existent.

Agricultural tractors are unknown in Belgium.

In the Brussels district there had been built up an interesting customs body-building industry, which received chassis from England, France and other nearby countries and returned them completely equipped with made-to-order bodies. Of the total output of the Belgian automobile factories, 70 per cent was for export. By destroying this industry, Germany felt she would have one less competitor to meet on the resumption of business after the war.

If an indictment of the German government was desired, the automobile industry would not be selected as an

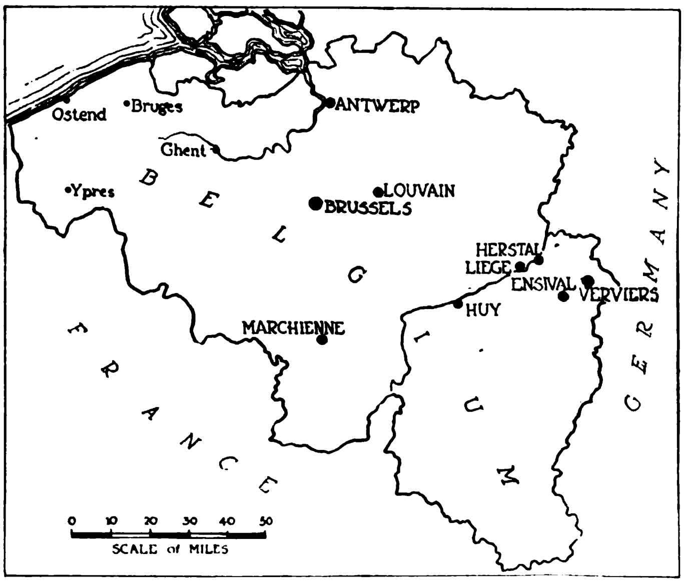
Dyle & Bacalan (frames, etc)	Louvain	Wrecked and burned in sack of Louvain.

example. While the sum of $10,000,000 represents the value of practically the whole of the machinery employed in the production of automobiles in Belgium, the total is too small in these days of colossal figures to strike the imagination of the masses.

The mining industry and the general engineering industry were bigger prey and, although the proportions are the same, the figures are much more impressive. To take one particular instance, there was at Seraing, a few miles from Liége, the John Cockerill Engineering Co., employing 10,000 men on the production of railroad material, steam engines, Diesel engines, cranes, etc. Externally the factory is in good condition. The words "Vive la Belgique" adorn its façade. The windows are unbroken, the bricks and tiles are all in place, everything is cleanly. But inside the destruction is so complete that the chief engineer declared to me: "I should very much have preferred that the whole place had been wiped out by a bombardment. In that case we could have drafted a new plan and have built an entirely modern factory. As it is, our walls are intact, but the machinery is gone, and we are obliged to rebuild within the old walls and with the old limits and restrictions."



Map of Belgium

Not a shot was fired over the Cockerill factory, yet destruction has been effected to the extent of $13,000,000 on 1914 values and more than 8000 work people have been deprived of their means of livelihood. When the German armies took possession of Belgian territory Cockerill was asked to work for the invaders. He refused. For a few months work in the factory continued, on a reduced scale, for the home and the Dutch markets. But as raw material became scarce and as the difficulties of preventing the products finding their way into Germany became greater the factories were closed.

Germany was early in the field for the Cockerill machinery. The high-class tools were removed by official requisition. Engineers from Germany came, examined, photographed, went home, and returned with orders to take possession of individual machines. There was keen competition for many of the best machine tools. One particular installation was photographed and reported on by ten organizations. Officers and engineers quarreled in the factory for the possession of this machine. Finally an officer and soldiers arrived, with a duly signed order from the central German authority at Brussels. A freight car was run alongside the machine, the locomotive remained hitched up, and within an hour, by the aid of the overhead crane, the machine had been loaded and had disappeared. An hour later another officer arrived with a signed order for the same machine. He rushed to the railroad station, but the car had gone; telegraphic messages were sent in every direction, but neither the Belgian nor the German authorities could discover where the machine had been taken to.

In 1914 the Cockerill company had built a gas engine of 10,000 hp. This was the biggest engine of its kind in the world and had been produced for the Cockerill generating station to save the space taken up by the small

Derihon Machine Shops as the Germans Left Them

individual engines and to prove that there was no practical limit to the size of gas engines.

The German engineers coveted this engine. A requisition order was presented authorizing its removal, and the directors given 4 hours in which to produce the assembly drawings; if not delivered within this time the directors of the factory would be deported to Germany. The 10,000-hp. gas engine, together with its dynamo, was shipped to Germany and is in operation in that country at the present moment. In order to dismount it rapidly the whole of the building in which it was housed was destroyed and the holding-down bolts were cut with an acetylene torch.

Even the electric standard and lamp at the entrance to the engine house were taken to Germany. A few of the machines were of German construction, and in several of these cases it was the German engineer responsible for the installation who took charge of the removal of the machines to Germany.

Until May 25, 1918, it was possible, by entreaty, by persuasion, by argument, to induce the Germans to respect portions of the plant which were absolutely essential to a resumption of activities. But on May 25 the R. O. H. M. A. swept down on the Cockerill factory and systematic destruction began and was continued without a stop until 10.45 a. m. Nov. 11, 1918—15 minutes before the armistice went into effect.

The R. O. H. M. A. was the terror of the Belgian factories. This organization was charged with the task of obtaining metal. If it could secure $500 worth of cast iron by destroying $10,000 machines it did not hesitate for a second. At the Cockerill factory the R. O. H. M. A. organization was in charge of Von Dip. Ing. C. Quasebart, professor of metallurgy at the German University of Aix-la-Chapelle. This von engineer proved a remarkable leader and should be capable of giving valuable instruction at his university on rapid and up-to-date methods of wrecking factories.

When Von Quasebart took charge at the Cockerill plant the great German offensives had been launched and appeared likely to succeed. Said one of the German officers to Mr. Tonneau, director of the Cockerill company: "This is the beginning of the end. We are certain to win. We shall not have to pay a cent to Belgium; we can do as we like." Add to this the fact that the only real competition the German engineering industry had to meet in the Dutch and Scandinavian markets came from Belgium and we have the explanation of the mad destruction ordered by the German authorities and executed by the R. O. H. M. A.

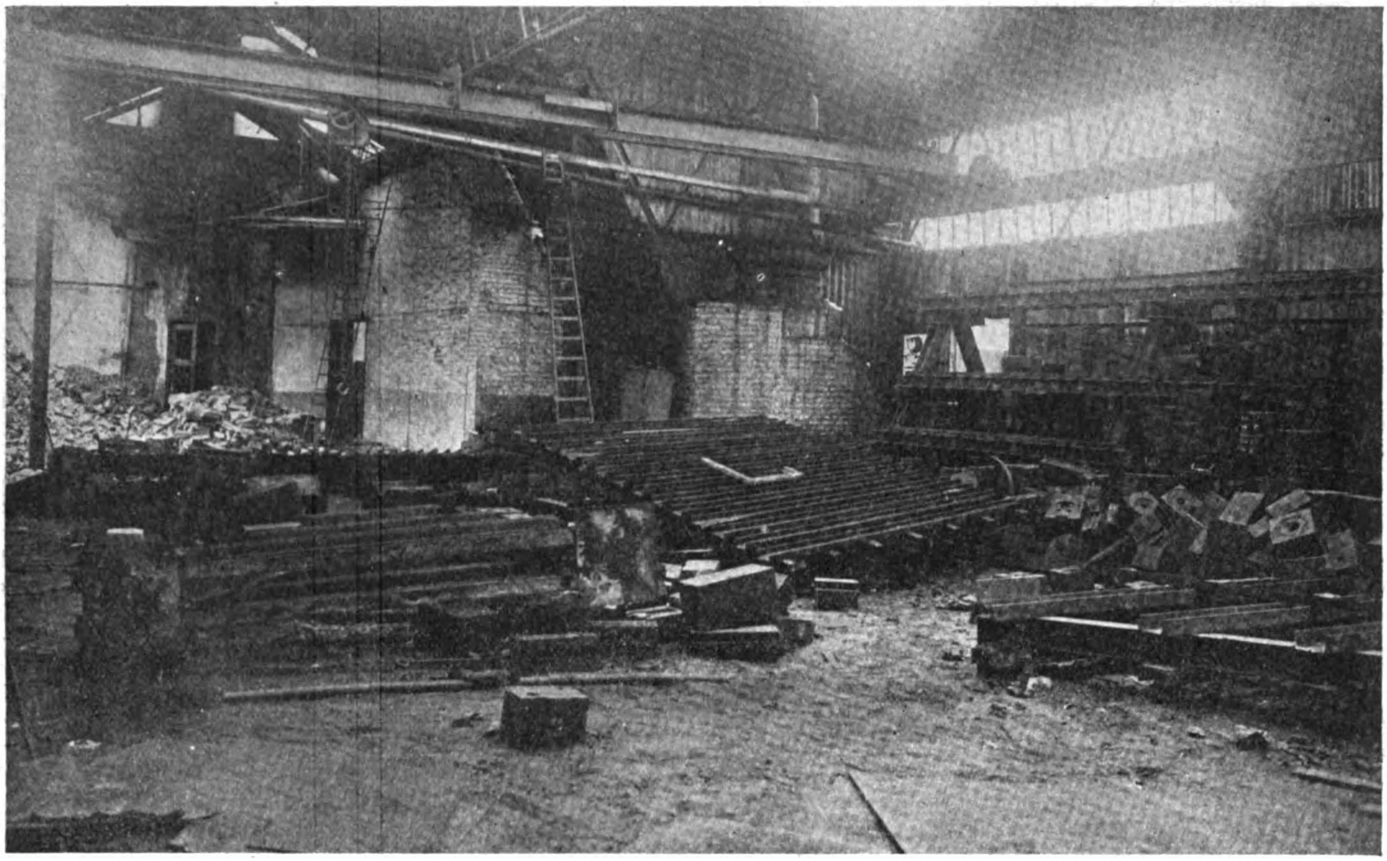
Germany's requirements, in order of importance, were copper, brass, rubber, leather, cast iron and steel. But when the R. O. H. M. A. came on the scene only iron and steel remained and the only object was to get scrap metal for the furnaces. In some cases overhead traveling cranes had been demounted and sent into Germany for further use. This so seriously interfered with the wrecking gangs that a general order was issued forbidding cranes to be destroyed. The method of operation was to cut the holding-down bolts with the acetylene torch, hitch the crane to a machine and drop it from a height of 6 to 12 ft. to break it. From their own standpoint the method was uneconomical, for from 20 to 25 per cent of the metal became embedded in the earth and could not be collected.

Nothing escaped: blast furnaces, rolling mills, cupolas, gas and steam engines, boilers, shearing machines, lathes, hardening furnaces, even the steel columns supporting the roofs of the buildings were pulled down and scrapped.

The first instruments employed were the acetylene

The Derihon Buildings Suffered Less Than Plant

(Photographs made after the armistice became effective)



This building was stripped of the steel portions and this was to be used as scrap. In the background the walls have fallen as result of removing pillars. Note the dies, which are treated as scrap

To facilitate the removal of machinery, the German troops destroyed a portion of this building

torch—it was too slow to unscrew nuts—and the crane. So great was the effort in tearing up machinery that the hook of the most powerful overhead crane was broken. Where no overhead crane existed, a block and tackle was attached to the girders. Engineers would have feared that the entire building would collapse. The Germans had the luck merely to break the girders.

For the big machinery, dynamite was used. If a building made the removal of a machine difficult, the building was destroyed. In some cases, after the holding-down bolts had been cut, the desired machine was attached to a traveling crane mounted on rails in the yard, and pulled through the window. After the first two or three efforts the opening was large enough to allow the free passage of the biggest machinery.

The Cockerill plant is described as an example of destruction on the biggest scale. The treatment accorded to the Derihon Brothers plant differed only in volume. A few miles to the north of Liége, the Derihon company possessed a modern plant devoted exclusively to the production of forgings and stampings for the automobile industry. Derihon B. N. D. steel had a universal reputation, and was always employed when the very best was desired. As an indication, practically all the essential parts of Peugeot and other French racing cars built before the war, and now in America, were of Derihon B. N. D. steel.

When the invasion began, one of the Derihon brothers escaped to England, where he erected a factory for the production of special alloy steels for automobiles and airplane engines. The technical staff, left behind, began the manufacture of shock absorbers in order to keep the workers employed and to forestall any excuse the Germans might offer for seizing the machinery. In 1916 the factory was asked to work for Germany. It refused, was threatened, and refused again. In consequence the plant was sequestered, or put into the hands of an official receiver. The plan was to remove the entire Derihon plant into Germany where it would be put into operation as a direct competitor after the war.

German engineers, who were specialists in the making of forgings, came to the factory, exacted the plans under threat of deportation, and superintended the removal of machinery and plant. One of these specialists was photographed. His name is not known, but the company he represents is the Rhein-Elbe Gelsenkirschner A. G. Abt. Aachener Hütten-Verein, at Düsseldorf. It is declared that the entire Derihon plant was to be transferred to this firm. The entire laboratory disappeared; the microscopic camera, the Brinell machines, the impact testing machines, the pyrometers, the chemical apparatus, the test pieces, even the diagrams, photographs, and charts on the walls were sent into Germany.

All Machinery Despatched to Germany

The furnaces, forges, drop hammers, presses, compressors, blowers, lathes, shearing machines, power saws, shafting, belting, wiring, electrical equipment were all pulled down, loaded on freight cars and despatched over the border for the benefit of the German industry. It was not until 1917 that the real work of destruction began, but during these 18 months the enemy had the time to tear out every machine and to remove every inch of shafting. The two steam engines were left behind, although marked for removal, but all the steam pipes were broken with a hammer and the boiler was pulled out and the tubes sawed through.

The wreckage was piled up at one end of the building until it went through the glass roof. Although everything had been torn out and labeled for shipment to Germany, time had been too short to get it all loaded on freight cars. At midday, Nov. 11, 1918, when the armistice became effective, German soldiers came to the factory to load goods for Germany. The Derihon staff had the satisfaction of kicking them out.

Derihon never was visited by the terrible R. O. H. M. A. But evidently there are other organizations no less destructive, for when it was abandoned the Derihon factory was in a condition defying description.

After practically everything had been removed it was learned from one of the soldiers that all the dies were to be taken for scrap metal. To avoid this terrible loss, the small staff left at the works smuggled many of the dies to a place of safety. The German soldiers saw the men at work and even helped to load some of the dies on a wagon, but were satisfied with the explanation that this was being done to facilitate the work of the soldiers who were to come on the following day. The officers were not so easily fooled. The manager of the factory was court-martialed and kept in prison for 3 months.

The Germans gave receipts for all machinery they requisitioned. Sometimes this was done correctly, sometimes it was not. At the Derihon factory one army department gave a receipt for goods seized and shortly afterward another army department took that receipt away by force. Derihon does not possess a single original receipt for machinery seized. The precaution was taken, however, of photographing all the receipts before the German officers caused them to be given up. One of these photographed receipts is shown on this page.

[In a further installment of this article Mr. Bradley describes other factories he visited by special permission granted to him as the representative of Automotive Industries.—Editor.]

Four Wheel Drive Trucks

Militor Four Wheel Drive Ordnance Truck Described and the Reasons for Its Design Discussed Before S. A. E. Metropolitan Section

THAT there is a wide field for the four wheel driven truck in commercial work was asserted by George Dunham and L. C. Freeman, in a paper read at the last meeting of the season of the S. A. E. Metropolitan Section, held on Thursday of last week. This field extends all the way from where that of the two wheel driven truck leaves off to where that of the chain track tractor begins. Mr. Freeman claims not only better weight distribution and greater adhesion under difficult traction conditions, but also asserts that as regards fuel economy and tire mileage, the two wheel driven truck will have to look to its laurels.

In the introduction of his paper Mr. Freeman explained that the subject would not be covered as broadly as the title "Four Wheel Drive Trucks" might indicate. He had been associated with Mr. Dunham in the development of the ordnance four wheel drive truck, and it was his purpose to describe the features of this truck and give reasons therefor.

The Ordnance Department saw the necessity for the use of the four wheel drive in trucks where the conditions of operation were very severe. The Militor Corporation was asked to develop a four-wheel-driven truck, and the author said that he wanted to acknowledge at this time the invaluable assistance that was given the engineering staff of the company by outside consulting engineers, and by the engineers of parts makers and other truck makers.

Features Desired by Ordnance Department

At the outset, elaborate and continuous tests were made on all four wheel driven trucks then manufactured in this country, as well as on a four wheel drive Renault tractor. Some of the features that the Ordnance Department insisted upon were high-ground clearance; light weight, short turning radius, short front overhang and low center of gravity.

In the design of the trucks, two objects were kept in view, namely, the greatest production possibilities and maximum interchangeability, even with parts of other vehicles. It was also endeavored to make the truck symmetrical as far as possible, as this tended farther toward interchangeability. One of the principles laid down for the design was that as each problem arose, it should be considered basically as a problem and anyone called in for consultation should be either convinced that the design selected was right, or else the plan of the consultant should be adopted.

In the first place it was decided that the standard seating arrangement, with the driver behind the engine, should be adopted. Next, on account of the requirement of a high-ground clearance, it was decided to adopt the internal gear driven axle, with the differential located on top of the axle.

When the problem of selecting a suitable engine came up, it was first suggested to make use of the Military Class B engine, but this plan was abandoned because it was found possible to obtain an engine already in production, which permitted of making the front overhang of the truck 6 in. less, and which also reduced the weight by 350 lb. The radiator was placed back of the engine, the chief reason for this being that it tended to reduce the front overhang. The reason for making the front overhang small, was clearly brought out in some of the moving pictures shown, which illustrated tests made with the truck under the most unusual and difficult conditions. If there is a large overhang in front, if the front wheels go into a ditch, the forward end of the frame is likely to strike the opposite bank. The picture showed that the Ordnance truck had no trouble of this kind.

Hele Shaw Clutch

For the clutch, the Hele Shaw was selected. It was found that it would be necessary to use a four-speed transmission with an unusually high reduction low gear, and the class B truck transmission was adopted, with the exception that the low gear was made special. The gear reductions required were worked out on the basis of the traction ability which had been specified for the class B truck. It was figured that in a two wheel driven truck only 80 per cent of the total weight is available for traction purposes. Hence, in a four wheel driven truck of the same total loaded weight, the traction ability should be greater in the proportion of 10 to 8. The Ordnance four wheel drive truck is a 5-ton machine and a gross weight of 16,000 lb. was figured upon, but as a matter of fact, the truck did not come out quite as light as had been expected. Gear reductions were selected in accordance with the traction effort requirement on high and low gears, the high gear reduction chosen being 9.6, and the low gear reduction 73.6:1. With this high gear reduction ratio and 40 in. wheels, the truck travels 15 m.p.h., at an engine speed of 1210 r.p.m.

While standard units were selected as far as possible, the transfer case, that is, the member through which the power is transmitted from the end of the transmission shaft to the propeller shaft, has no equivalent on two wheel driven trucks, and had to be designed specially. In the design of this member, consideration was given to the different methods of power transmission by spur gears, silent chain, etc., and a decision in favor of the silent chain was finally made. Means for adjusting the chain tension were provided which allowed of using the chain for a much greater length of time. The two chain wheels of the transfer case were made of nearly equal size, so that by interchanging them, a different reduction ratio could be obtained.

Universal Joints and Propeller Shafts Identical

The two universal joints and propeller shafts were made identical and interchangeable. The differential housings of the front and rear axles were also made identical and interchangeable. Brakes were located on both sides of the differential housing.

It was known in advance that the truck would be used under very difficult conditions, and the greatest attention was paid to provisions against frame distortion. Full 3 point suspension is used, and the drive and torque reaction are taken up on the spring. The latter are symmetrical and interchangeable.

There were really only three parts to the truck that were entirely new, these being the axle, the transfer case and the radiator, all other parts being stock parts which could be purchased in the open market. The truck was provided with a winch which was designed with a reduction gearing of such power as to be capable of breaking a new 1½-in. manila rope.

Commercial Use of Four Wheel Driven Truck

In concluding his paper, Mr. Freeman made some references to the outlook for the four wheel driven truck in the commercial field, stating that this type of vehicle fitted in between the two wheel driven truck and the caterpillar. He admitted that there were more parts on a four wheel driven truck, and that the cost of manufacture would be slightly greater, but said these parts were duplicates of other parts, and they were smaller than the corresponding parts on a two wheel driven truck. The tire life, he said, had been found very satisfactory with four wheel driven trucks, which was probably due to the fact that since the driving effort was divided between all four wheels, the strain on the tire was comparatively low. In regard to fuel consumption, also, he regarded the four wheel truck as on a par with the two wheel driven machine.

Colonel L. B. Moody, of the Ordnance Department, who is in charge of the transportation of this department, was present, and made some remarks on the need for four wheel driven trucks in ordnance transportation. Colonel Moody said that the four wheel driven truck described in Mr. Freeman's paper was one of the finest pieces of engineering work ever turned out for the Ordnance Department. He dwelt at length upon the reasons why four wheel driven trucks were needed for ordnance transportation. In connection with military operations, there are two kinds of transportation: transportation directly behind the fighting line, where the roads are usually torn up by shells, and transportation in the rear. The former constitutes practically 50 per cent of all the transportation work necessary.

Two Wheel Driven Trucks Fed Guns at Front

The point has been made that our Allies used very few four wheel driven trucks, but this was due to the fact that they used animal transportation very largely, directly behind the lines. The American Army discarded animal transportation on account of the difficulty of getting the horses to Europe and of shipping the necessary feed. Under certain exceptional conditions, two wheel driven trucks could be used effectively close to the battlefront. Thus, during the Somme battle, a couple of days before the British took Peronne, two wheel drive trucks fed the guns at the front very nicely, but this was possible because the Germans in their retreat, for one reason or another, failed to mine the roads. Directly north and south of the section to which this remark applies, there was hardly a ghost of a road, and even a tank had trouble in getting ahead.

Experience With Trucks at the Front

During the American offensive in the Argonne, some two wheeled trucks were also being used for hauling up ammunition, and they got stuck promptly. The ammunition was thrown off, and they could not even extricate themselves when empty, with the result that the road was blocked for four hours. When the Ordnance Department cut out horse transportation, it had a choice between four wheel driven trucks and caterpillars. The latter were largely used, but owing to the larger field of service for four wheel driven trucks it was decided to also develop this class of vehicle.

Some additional information regarding the Ordnance truck was brought out in the discussion. Thus, it was stated that one reason for the rear location of the radiator was that it was better protected against shocks in that position. Self-locking type differentials were used, and gave very satisfactory service. It was known in advance that these would see very severe usage, and thus what might be called an oversize was selected. The Ordnance 5-tonner was made both as a truck and as a tractor, and one of the differences between the two models was that the truck had two wheel steer, while the tractor had four wheel steer. In the tractor, both the front and rear axles were identical and interchangeable.

No Trouble with Locking Differentials

In answer to a question, Mr. Dunham said that some of the trucks had been run 25,000 to 30,000 miles and not the least trouble had been experienced with locking differentials, which, when they had been taken out, had looked as good as new. As regards fuel consumption, it was stated that the truck would do 3½ miles on a gallon of gasoline.

It was found that in order to secure traction under the most difficult conditions it was necessary to use 14 chains on each wheel. At first only 6 chains were used, but on soft or slippery ground the wheel would begin to slip when no chain was on the ground and would dig itself in.

Resistance of Animal Glues to Moist Air

THAT there is a close relation between the viscosity, and therefore the grade of animal glues and their moisture resistance is strongly indicated by recent tests made at the Forests Products Laboratory.

Test specimens were made of two pieces of ⅛-in. birch veneer glued together with the grain in opposite directions so as to give 1 sq. in. of glued joint surface. The specimens were suspended in a humidity chamber with a 1-lb. weight hung on each, and the time required for failure of the glue joint was noted. The first two tests were made at 98 per cent humidity. In the third test the specimens were kept at 90 per cent humidity for 120 hours, after which the humidity was raised to 98 per cent. No failure occurred at 90 per cent. The temperature used in each test was about 80 deg. Fahr.

The results indicate that the moisture resistance of animal glues is proportional to the viscosity, jelly strength and grade.

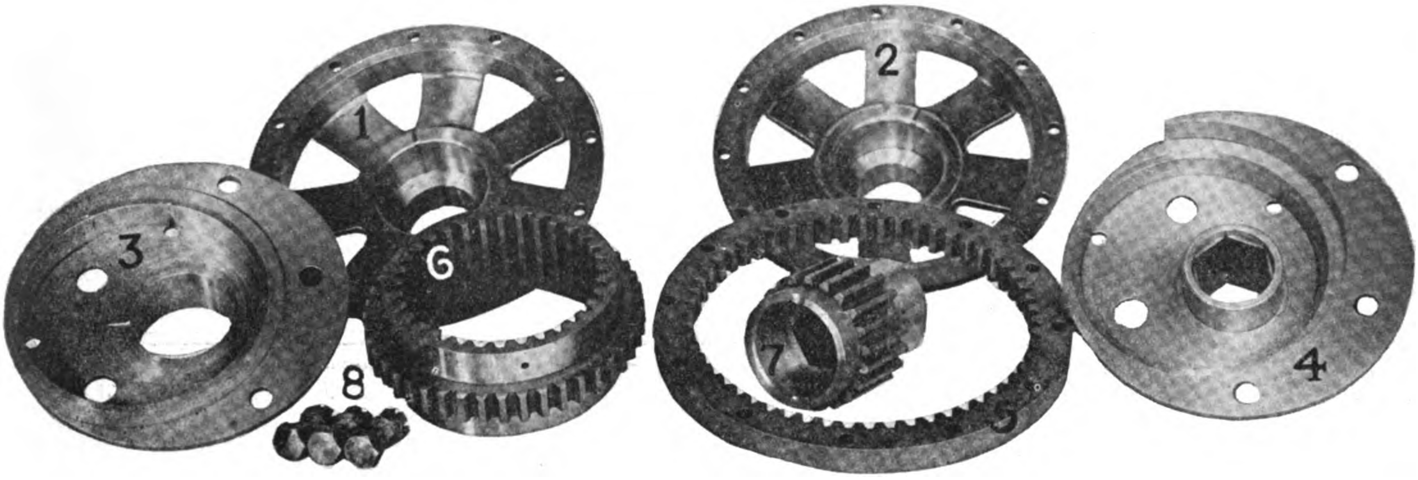
The Elbertz Positive Drive Differential

An Adaptation of the Epicyclic Gear to a New Purpose—Prevents Slipping of Wheel Without Traction and Drives Through Inner Wheel at Corners

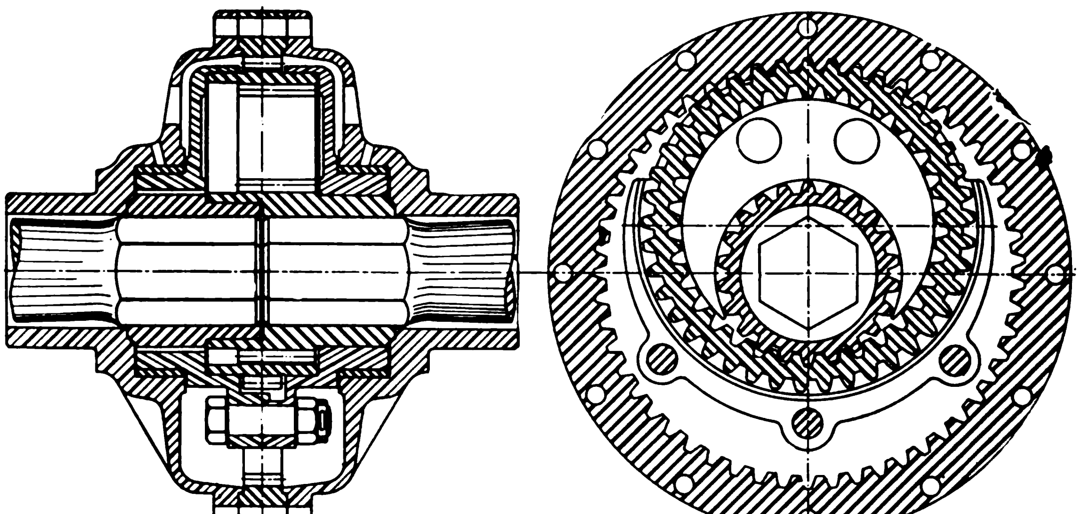


Parts of the Elbertz positive drive differential

THE Elbertz positive drive differential is a new design of differential gear intended to obviate spinning of drive wheels and consequent loss of traction when one wheel of a truck or car gets onto a piece of slippery road. When driving straight ahead it distributes the power to both driving wheels up to the limit of their respective traction abilities. Under normal conditions the power is delivered equally to both wheels, but when the traction limit of one wheel is reached the excess power is delivered to the other wheel up to the limit of its traction. In turning corners it allows the outer wheel to run ahead of the inner one.

The Elbertz differential comprises seven main members, as shown in the accompanying illustration. These are known, respectively, as the differential cases 1 and 2, the crank members 3 and 4, the internal gear case 5, the intermediate gear 6, the shaft gear 7, and three sets of bolts and nuts 8, the latter retaining the two crank members as one unit when assembled. This differential gear is an ingenious arrangement of an epicyclic train of gears, consisting of an internal gear case 5, secured to the differential housing, 1 and 2, which in turn meshes with intermediary gear member 6. The latter can revolve about a bearing on the crank arm or eccentric member 3, 4. The eccentric member engages with one axle shaft and turns with it. The other axle shaft engages with shaft gear 7, the latter meshing the internal teeth of the intermediate gear member 6.

We are informed that the parts shown in the illustration were photographed after being in service in a prominent make of 3½-ton truck, which had covered approximately 9000 miles up to the time of disassembling. We are also informed that several axle builders have secured manufacturing rights from the B. F. Everitt Co., of Detroit, the licensor, and are now producing differentials for their own requirements.



Two sectional views of Elbertz positive drive differential

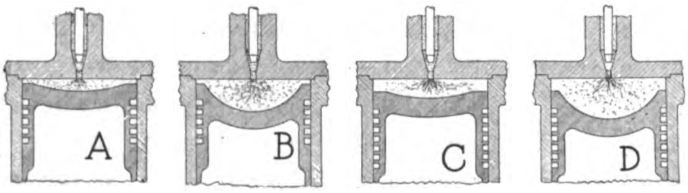
—

WITH so-called closed circuit battery systems of ignition the contacts of the interrupter may remain in closed position when vehicle stops. This causes overheating of coil and runs the battery down. In order to prevent this from occurring, a method is given in French Patent No. 486105 of the Soc. Anon. pour l'Equipment Electrique des Véhicules. A relay is provided by which the current flowing in the primary winding of the spark coil is interrupted. The current taken by the relay winding has to pass through a filament of one of the rare earths that only become conducting at high temperatures. The heating of this filament is produced by a resistance in the circuit of the primary winding. The relay is so designed that, having acted at a given temperature of the filament, the primary circuit of the spark coil is kept open until it is closed by pressing a knob that resets the armature of the relay.

Diesel Engines for Automobile Work

Method of Fuel Injection and Conditions of Combustion Limiting Factors—Fuels Available for Use in Diesel Engines

SOME light was thrown on the difficulties encountered in adapting Diesel engines to automobile work in a recent paper by Charles Day before the Institution of Automobile Engineers. According to Mr. Day, the method of introducing the fuel into the cylinders and the conditions of combustion are at present the limiting factors.



Form of combustion chamber with short and long strokes respectively at beginning and end of fuel injection period

In regard to the spraying of the fuel into the cylinder, it will be readily appreciated that time is a factor in forcing oil through a pulverizer, also that as the viscosity of the oil increases the time required to force the oil through will increase, unless the pressure behind the oil is increased or the design of the pulverizer modified. With free-flowing petroleum residue oil, and with an air pressure of about 1000 lb. per square inch, the author is of opinion that pulverizers of prevailing designs can, with suitable oils, be arranged to deal with speeds up to about 500 or even 600 r.p.m. At 600 r.p.m. the time during which the oil has to be sprayed into the cylinder is approximately 1/200 of a second. For higher speeds pulverizer modifications will need to be developed.

The character of the fuel oil is a factor in the permissible engine speed, both from the point of view of pulverization and of combustion. Viscous oils are more difficult to pulverize than thin and free-flowing oils, and cannot be put through a pulverizer so quickly.

Rate of Combustion Dependent Upon Fuel

Again, the combustion of heavy and tarry oils is not so rapid as that of refined oils, such as kerosene or gasoline, and if the engine speed is so high as not to allow sufficient time for the combustion of the fuel, difficulties will arise from sticky valves, smoky exhaust or dirty cylinders. For rapid combustion, a very finely divided spray is of importance, as obviously large drops of oil take a longer time to burn than very small ones.

From this it would seem that high speed engines may need refined oil, in which case one of the great advantages of the Diesel engine will disappear.

The fuel is sprayed into the cylinder during a very short period of the stroke, commencing with the piston at approximately the top of the stroke. With a short stroke engine the combustion space into which the oil has to be sprayed is very shallow, as owing to the high compression necessary the clearance volume must be low, say about 7 per cent of the total cylinder volume. Remembering the small clearance space, the difficulty of spraying the oil so as to distribute it throughout the air is obvious. Failure to thoroughly mix the oil spray and air will lessen the possible power of the engine by reducing the quantity of oil which can be burnt.

Improvement in distribution is obtained by dishing the piston top. In the accompanying illustration, *A* shows diagrammatically the best obtainable combustion space for a short stroke engine, assuming reasonable clearance between the outer edge of the piston top and the cylinder head, while *B* shows the possible shape of combustion space if the stroke of the piston is doubled.

The combustion space at the latest point of fuel admission is shown by *C* and *D* respectively. A glance at these diagrams shows how much easier the spraying problem becomes in the long stroke engine than it is in the short stroke engine, especially when it is remembered that it is desirable to avoid spraying or splashing the fuel oil on to the water-cooled cylinder head or on to the piston.

In connection with gasoline engines, much attention has been given to the production of a turbulent condition of the gases at the time of ignition; in the author's view such a condition at the commencement of spraying-in is not so important in a Diesel engine, but, on the other hand, a considerable amount of turbulence should result from the spraying-in of the oil so as to insure the utmost possible mixing of the oil and air.

Another factor which must be kept in mind for automobile work is range of speed. In the Diesel engine ignition depends upon the temperature of the air at the end of compression, but if the speed of the engine is reduced very much it may happen that the cooling effect on the slowly compressed air is enough to prevent the compression raising the air temperature sufficiently for ignition. There is thus a limiting factor to the slowness of speed, and the range of speed permissible with the Diesel engine is not so great as with gasoline engines, in which the ignition is obtained by means of a spark.

Difficulties to Be Overcome

Before Diesel engines are likely to be applied extensively to automobile work, development along the lines indicated will be ncessary, so that higher speeds of rotation can be adopted and reduction of space and weight thus secured.

The difficulties to be overcome before the Diesel engine is suitable for automobile work have been stated, but it is important to make clear that the expression "automobile work" is not intended by the author to cover locomotives, for the Diesel engine as at present developed is applicable to locomotive work, and should find an important field there, owing to the great economy of working. For outlying districts and for long journeys through sparsely populated areas and countries, locomotives operated by Diesel engines should prove very advantageous, as for such districts electrical operation from fixed power stations is unsuitable.

Compared with the steam locomotive of existing types, the internal combustion locomotive would be cheaper in fuel, and would, if operating electrically, give much higher torque both when starting and when climbing stiff gradients, and it would also use a much smaller quantity of water. Reliability in service and a reasonable cost of upkeep will come with experience. The elimination of stand-by losses and immediate readiness for use are factors of importance in this service.

Fuel Oils

A very wide range of fuel oils can be used in Diesel engines, as, for instance, petroleum residues, tar oils, some crude tars, shale oils, kerosene, naphtha, alcohol or gasoline. Gasoline is only mentioned to illustrate the wide range of fuels permissible, and not as a desirable fuel, for obviously the much cheaper oils would be selected. As already explained, the working of the engine depends upon the spontaneous ignition of the oil when sprayed into the hot air in the combustion space—hence the temperature at which the spontaneous ignition of different oils occurs is a matter of importance.

The Bargaining Tariff

THE United States should have the means of properly protecting itself whenever our trade is discriminated against by foreign nations, in order that we might be assured of that equality of treatment which we hope to accord and to promote the world over. Our tariff laws as they now stand provide no weapon of retaliation in case other governments should enact legislation unequal in its bearing on our products as compared with the products of other countries. Though we are as far as possible from desiring to enter upon any course of retaliation, we must frankly face the fact that hostile legislation by other countries is not beyond the range of possibility and that it may have to be met by counter legislation.—PRESIDENT WILSON *in Address to Congress.*

WHEN President Wilson mentioned a retaliating tariff, or as it is commonly known, a bargaining tariff, in his address to the present session of Congress, he touched upon a problem that is being seriously considered by the Departments of State and Commerce and the U. S. Tariff Commission. His plan, which calls for a bargaining tariff that will allow the United States to enact discriminatory provisions against foreign countries that discriminate against us, is one which has been approved of by the U. S. Tariff Commission, but is looked upon as a doubtful measure by other governmental departments and officials.

The bargaining tariff is a system somewhat different from the European policies. France, for example, has a maximum and minimum system in which there are two rates fixed by the Legislature, according to the statement made by William S. Culbertson, member of the U. S. Tariff Commission, in an address before the Sixth National Foreign Trade Convention.

Germany, he said, has a general and conventional tariff system in which there is a general schedule of rates fixed by legislation and a lower conventional schedule of rates fixed by bargaining with other countries and embodied in treaties and conventions.

The United States has clung to the single-tariff system with only occasional attempts to make it more flexible. It now proposes to enter upon the policy that a nation deserves and seeks equality of treatment in international dealings. It plans to enact tariff legislation giving equality to all nations, but carrying a power to discriminate by means of high import duties against those nations that discriminate against us.

Officials Object to Plan

Objections to this plan have been voiced by officials who maintain that the only course that is profitable and logical is one whereby this country will conclude individual treaties with the different nations and in which those commodities that the United States produces to the greatest quantities and is most desirous of exporting will be specifically arranged for.

The United States tariff act of 1890 provided for certain bargaining methods, but these were found undesirable. Hides and certain edibles were admitted free of duty, and the President was authorized to proclaim without further act of Congress special penalty duty on these products when they were imported from any country that imposed unequal or unreasonable duties on American products. This was penalizing, not a discrimination against the United States but rather a high levy on American goods, a levy higher than was regarded as fair, and the President was consequently given the power to place the goods of one nation on a less favorable basis in our markets than similar goods imported from other countries.

Penalty Provision in 1909 Tariff Act

In 1897 the tariff act included three bargaining provisions, all offering and seeking special concessions. One provision was similar to that of 1890, another authorized the President to make special reduction on certain commodities in return for reciprocal and equivalent concessions. The third provided that any such treaties would have to be approved by Congress before they became effective. Most of the treaties failed ratification in the Senate and therefore never took effect.

In the tariff act of 1909, and which terminated the provisions of the 1897 act, a penalty provision was included to remove discriminations against American interests in foreign markets. It was based on the principle that every country granting our products equal treatment with similar products of other countries was entitled to equal treatment in our markets. There was a maximum tariff and a minimum tariff, the maximum tariff including an additional 25 per cent ad valorem rate to the minimum tariff. The President was authorized to grant the minimum tariff to those countries which imposed no discriminations on American products and the maximum where there were discriminations. This tariff act was found somewhat sound in principle but not sufficiently flexible. Many of the countries continued their discriminations regardless of the imposition of the maximum tariff.

This act also included the ratification of Congress be-

fore the agreements with foreign nations could become effective. The U. S. Tariff Commission objects to this provision because it states that in the complex conditions of commercial bargaining no consecutive policy can be carried out by negotiating treaties or agreements here and there which, in each case, must be submitted to the Senate for ratification or to Congress for approval.

Again in 1916 Congress enacted a provision for retaliation against prohibitions of American imports into foreign countries, allowing the President to prohibit the importation into the United States of articles from any country that prohibits the importation of similar articles from the United States.

The U. S. Tariff Commission in its report recommended that the United States should ask for no special favors and should grant no special favors, but should exercise its powers and impose its penalties not for the purpose of securing discriminations in its favor but to prevent discriminations to its disadvantage, and recommended the enactment of legislation authorizing the imposition of additional or penalty duties at the discretion of the President against the countries not granting equal treatment to the United States.

This is the policy that meets with objection in many of the official quarters in Washington. It is pointed out, for example, that an automobile tariff act by England might specify certain weights, prices and power alike to all countries and yet be discriminatory against the United States because the cars with the highest duties applied to them might be those manufactured in this country. For instance, the United States exports chiefly low-priced, light-weight, lesser power cars to England. France manufactures higher priced, heavier and higher powered machines which she sells to England. If a tariff act specifies a particularly high duty against the lower priced, the lower power and lesser weight cars without mentioning any country, it would be a discrimination against the United States, but it would be equal treatment to all countries literally and could not be denounced by this country.

It is because of this condition and similar conditions that there are opponents to the bargaining tariff plan who are in favor of concluding separate individual treaties with each country.

Again there are objections to the bargaining tariff which would discriminate against similar products imported from abroad when the foreign country discriminated against like products imported from this country. It is pointed out that the United States is the greatest manufacturer of automobiles. No other nation would be seriously harmed if we attached a high duty against automobiles imported into this country as a penalty to nations which placed a high duty on automobiles imported from the United States. The results could only be harmful to this country, as it would reduce the exports, while having no effect on the automobile imports, which form an insignificant amount.

The legislation favored by the tariff commission calls for an act in which Congress should define in general terms the kind and degree of unequal treatment which is to be penalized, which will enable the President to penalize not only upon discrimination, but also those discriminations more or less concealed in custom regulations, transportation rates, sanitary provisions, classification, etc. This legislation would eliminate the objection that now exists against penalties imposed on similar commodities.

The law should also name a variety of products selected with the view of inflicting a maximum penalty on foreign countries that discriminate against us and the minimum injury to the American consumer, and it should enumerate all the articles or commodities on which the penalty or maximum duties may be imposed and should specify the maximum limit of these duties. It should permit the President a free hand to administer the law within these limits in order to insure the necessary flexibility.

How Industry Can Aid

IT will be particularly profitable to American industry to take an active hand in the formulation of the new tariff laws which will be considered by the present Congress and which were suggested by the President in his message.

Congress comprises chiefly men thoroughly versed in law and less familiar with business. The Revenue Act is an excellent example of Congressional construction. It is now an act filled with conflicting and dubious phrases due solely to the lack of intimate knowledge of the details of each industry that would be necessary to insure a fool-proof and equitable law.

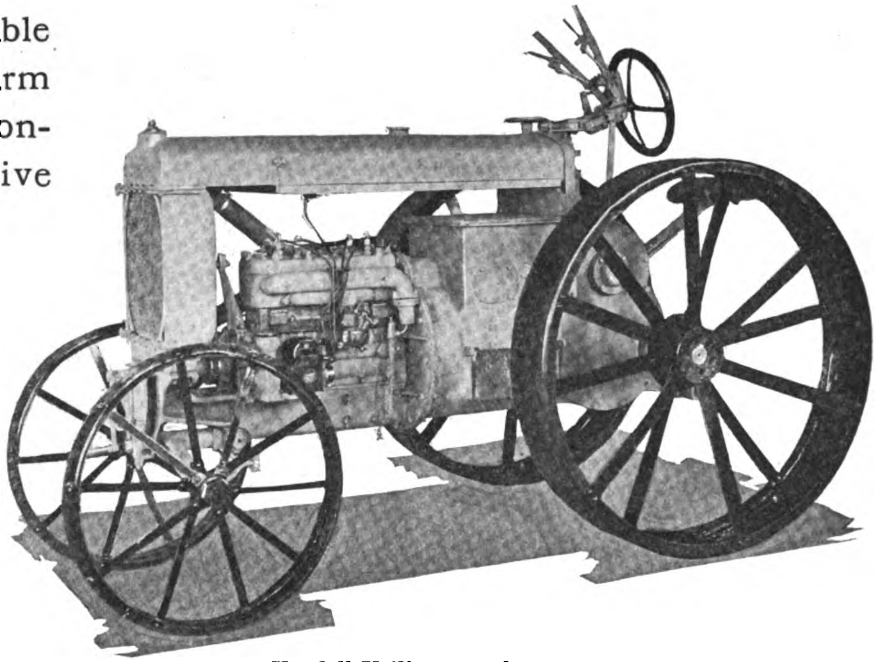
It was not possible for Congressmen to know, for example, of such details as the practice of dealers buying chassis and bodies separately and bolting them together. And it is not strange that no provision was made to prevent the double taxation that occurs with this transaction.

Similarly Congress does not know the intimate details of the automotive industry in its relation to a tariff, and whether we have a series of tariff treaties, a bargaining tariff or some other form, it is essential that industry should take an active part in drafting the bill.

Our export trade, which has gathered such great momentum and now gives promise of huge development, can be ruined completely by the formulation of a law that lacks the fine points which business men only can add to it.

Kardell Utility Tractor

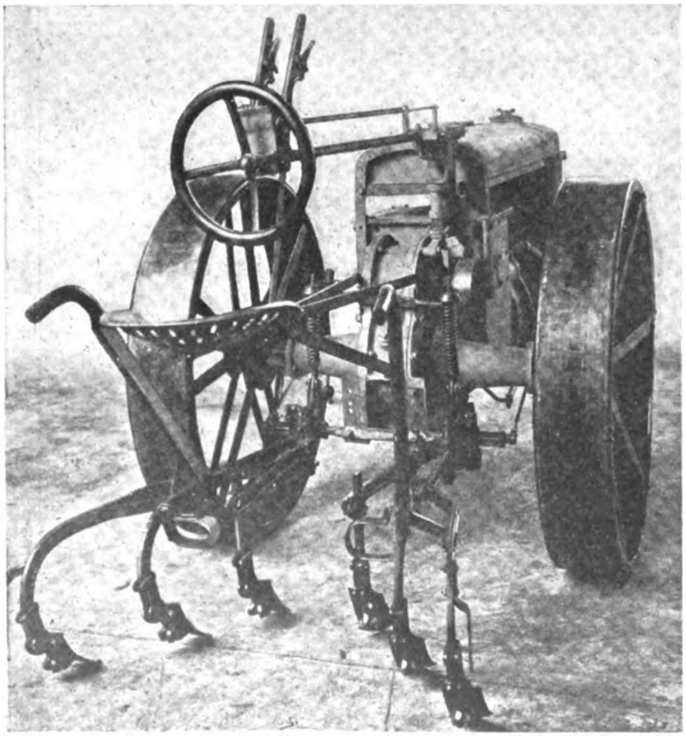
A 2-Plow Tractor Also Suitable for Cultivating and Other Farm Work—Backbone Frame Construction and Enclosed Drive



Kardell Utility two-plow tractor

A LIGHT tractor with several up-to-date features is announced from St. Louis by the Kardell Tractor & Truck Co. In the words of the makers, the utility of the machine is not limited to plowing and other operations necessary in preparing the seed bed, but it serves equally well for handling any type of cultivator, mower, grain or corn binder, hay rake, manure spreader or wagon, and for belt work. The machine is of compact design, the four-cylinder engine and transmission, bolted together, spanning the distance between the front and rear axles, and the wheelbase is comparatively short. The engine is of the company's own make. It is a four-cylinder design, of 3¾-in. bore by 4¼-in. stroke, all four cylinders being cast in a block, with a detachable cylinder head. The crankcase is cast separately and is of the barrel type. It is cast at the rear end with a large flange, to which the transmission is bolted, and at the front with a heavy bracket swiveled on the front axle.

As regards fuel, the makers say that either gasoline or kerosene can be used. The fuel tank, which forms the cover over the engine, is of heavy gage sheet metal, and is of ample capacity. A Bennett carbureter is used, and all air is drawn in through a Bennett air cleaner. Ignition is by a Dixie high-tension magneto with impulse starter. Lubrication of the engine main bearings is by force feed, but all other bearings are lubricated by splash. The plunger-type oil-circulating pump is clearly shown in the side view of the tractor. All gears are fully enclosed in a dustproof case and run in oil. Circulation of the cooling water is effected by gravity. The honeycomb radiator has cast-iron top and bottom tanks and side spacers. The latter are strong enough to afford ample protection to the radiator core. The total water capacity of the cooling system is 10 gal. It will be noticed that the belt-driven fan behind the radiator is enclosed by a shroud.



Rear view of Kardell tractor, with cultivator attached. Note seat and control extension used

Transmission Design Unconventional

The arrangement of the transmission is out of the ordinary. There are two parallel shafts back of the engine, a primary shaft in line with the engine crankshaft and bolted to it and a secondary shaft vertically above the former. The primary shaft is of the splined type and carries three gear pinions of ample face width upon it. Two of these pinions, for the first and second forward speeds respectively, can be slid along the shaft by means of a suitable sliding arm. The secondary shaft carries three large diameter spur gears, for the first and second forward speeds and the reverse speed respectively, the two forward speed gears being combined in one. All these gears are free upon the shaft, but can be secured thereon by plate clutches of the Kardell company's own design, one clutch serving for the two forward speeds and the other for the reverse. Thus, there are two independent friction clutches, one for forward operation and one for reverse, and as these are not located inside the flywheel the gear case is somewhat more bulky than is usual. Naturally, as the clutches operate at a much lower speed than if they were carried on the primary shaft, they have to be of considerable size. The speeds of the tractor are given by the company as 1½-2½ m.p.h. on low gear and 3-6 m.p.h. on high gear. This points to the fact that no governor is used, and the speed can be controlled by the throttle to quite an extent. From the secondary shaft of the transmission the drive is through a bevel pinion and bevel gear to an intermediate shaft on top of the rear axle, and thence by spur

gear to the differential gear on the rear axle. All gears are completely enclosed and run in oil. Anti-friction bearings are used throughout the drive.

A belt pulley is provided; it is not visible in the illustrations. It is located at the forward end of the tractor, parallel with the wheels, and any belt slack can therefore be quickly taken up. The pulley has a diameter of 9 in. and a width of face of 5 in.; at normal engine speed it turns at 1000 r.p.m., giving a belt speed of 2300 ft. per minute.

The rear axle is of the live type, and carries the differential gear at the center. The central portion of the axle housing is cast integral with the transmission housing, and over the large openings in this central portion are secured horn-shaped housings of cast steel, which surround the axle shafts. Gurney ball and Hyatt roller bearings are used in the rear axle and Timken roller bearings in the front wheels.

Driving Wheels of Latest Tractor Design

The driving wheels are 48 in. in diameter by 8 in. width of face, and are equipped with quick-detachable lugs. These wheels are of the latest tractor design, with flanged rolled-steel rims, flanged cast hubs, and flat spokes which are riveted to both hub and rim. The front wheels are 36 in. in diameter and are provided with skid bands. Steering is by means of a hand wheel on a rearwardly extending shaft which carries a bevel pinion meshing with a larger bevel gear on a vertical shaft. The steering gear is so arranged that the tractor can be operated from the implement. Directly in front of the steering wheel there is a double sector on which the clutch and change-gear levers are mounted. A band brake is fitted to a drum on the shaft of the spur pinion, outside the transmission housing.

The hitch of the Kardell tractor is located 7 in. below the center of the draft line, which is claimed to obviate all tendency of the tractor to "rear." The I-section front axle is so mounted as to allow a free movement of oscillation, thus permitting the tractor to accommodate itself to any unevenness of the ground surface, and of running the wheels on one side of the tractor in the furrow without subjecting the tractor to any additional strain. The front end of the engine crankcase forms a support for the front axle and radiator, starting crank and belt pulley. The spring support of the front end is shown in the longitudinal sectional view, and although the spring used is of the coiled type there is no sliding motion corresponding in extent to the spring play, the part on which the spring rests having a pivot support on the bottom of the crankcase, and having only a slight rocking motion.

The total length of the Kardell Utility tractor is 98 in., and its width 56 in., but the driving wheels can be reversed on the axle and thus the width reduced to 40 in. when desired. The height of the tractor is 52 in. and the weight approximately 2200 lb.

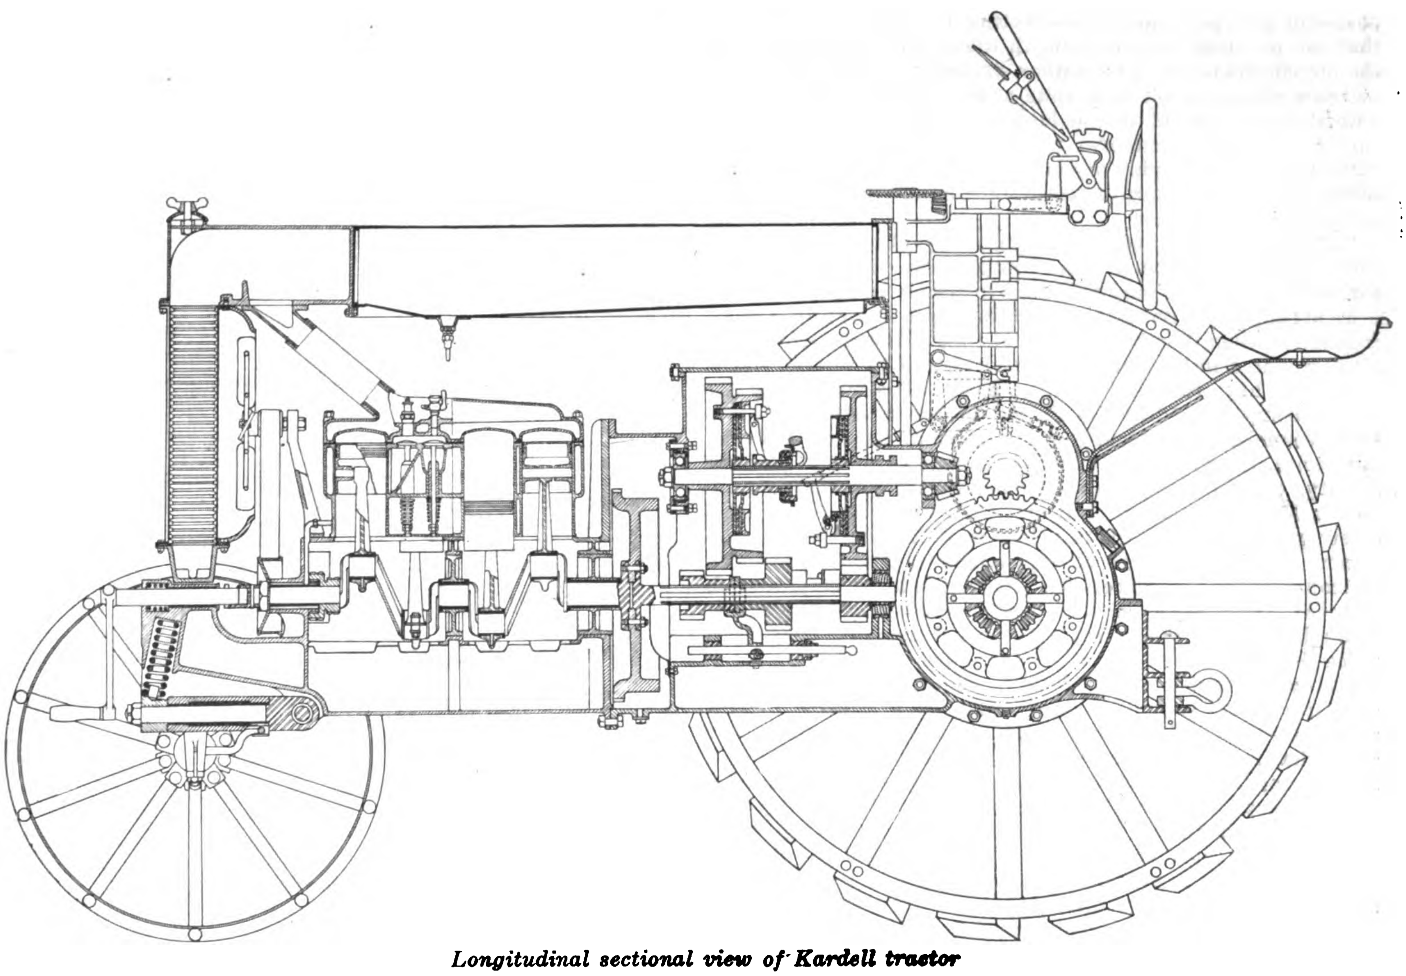
The tractor is rated at 8-16 hp., and is recommended for pulling two 14-in. plows. Provisions are made on the engine for installing an electric generator for night illumination and also for mounting an electric starter.

There is a dash secured to the rear end of the transmission housing, and the fuel tank extends between this dash and the overhanging top water tank of the radiator.

Anti-Friction Bearings in Grain Binders

AN important advance in the construction of grain binders has just been made by the Moline Plow Co., Moline, Ill., which has adopted the use of Hyatt roller bearings in its binders.

One enthusiastic writer compares this step to the invention of the Marsh harvester in 1864 and the development of the Appleton knotter in 1880. Not less than 37 of these anti-friction bearings are used on the Moline, and among the advantages gained are that the friction is reduced, the need for the daily oiling of numerous bearings obviated, and the binder is suited for operation at tractor speeds, which are considerably higher than horse speeds.



Longitudinal sectional view of Kardell tractor

Benzol Production at Gas Works

Steps Being Taken by British Benzol Producers to Insure General Distribution of the Fuel—Description of a Small Rectification Plant

PREVIOUS to the war benzol was used as a motor fuel only in France and Germany, but in recent years much interest has been aroused in its possibilities in Great Britain and some even in the United States. Great Britain is interested chiefly because of her keen desire to find a suitable home-produced fuel. It is only natural that most of the pioneer work in connection with new fuels should be done abroad, because the United States is the greatest petroleum producing country in the world and the price of gasoline has always been materially lower here than in the principal European countries. However, we have recently had our attention focused on the fact that our unmined supply of petroleum is rapidly dwindling, and as this is brought home to the consuming public and to the industries which are mainly dependent upon a volatile liquid fuel interest in substitute fuels will grow rapidly.

Most people having anything to do with automobiles know that benzol is a by-product of the coking of coal in gas works or coke oven establishments, but few know anything of the details of the process nor of the quantities in which the fuel may be recovered. Some light is thrown on these subjects by a recent article in *The Engineer*.

The Problem of Distribution

"The sudden termination of hostilities found British gasworks and coke-oven undertakings wholly unprepared with a post-war policy as to the marketing of their benzol. Now that the producers are faced with the problem they find that the distribution of several million gallons per annum is by no means a simple problem, in spite of the demands for the fuel. Two distinct lines of action have been proposed, namely, to turn the whole output over to the gasoline interests and to make use of their highly organized distributing machinery, or to set up the necessary organization for an entirely separate scheme of distribution.

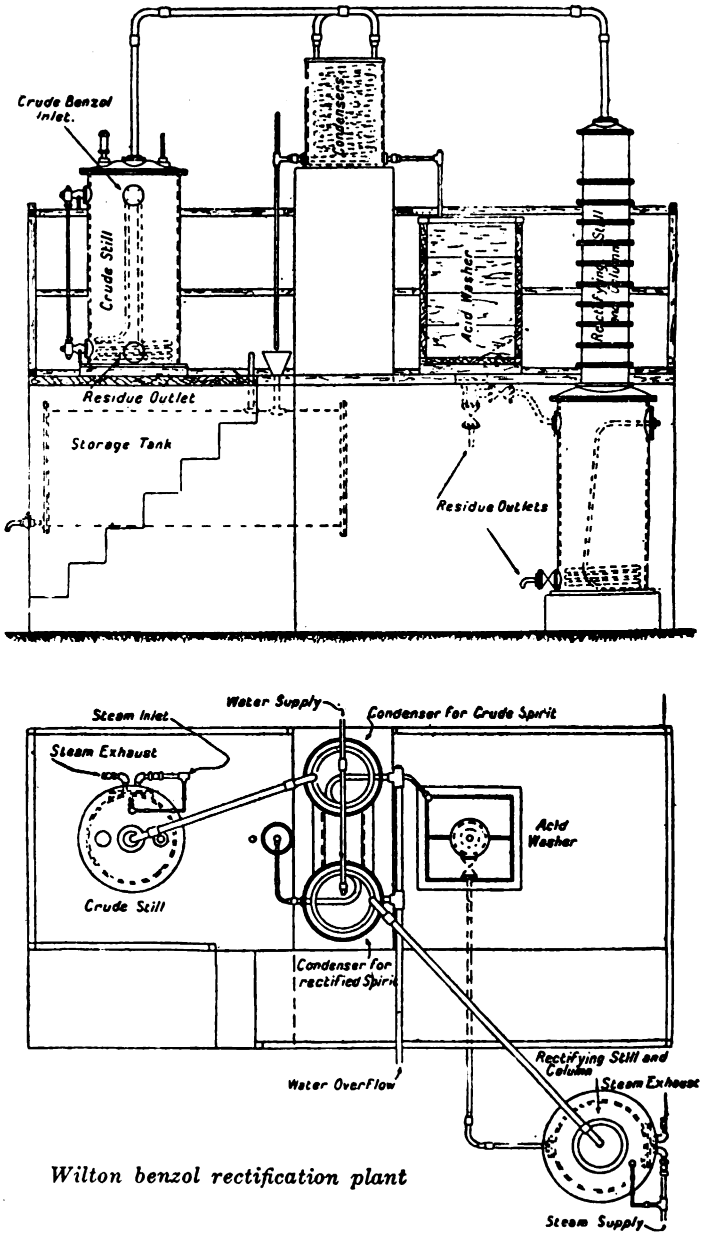
"At the present time, of course, many of the large coke-oven undertakings place their benzol at the disposal of motorists, but they are only prepared to supply in 50-gal. drums—an arrangement not altogether alluring to any but the large consumer, when it is borne in mind that coke-oven works are all segregated in the northern districts, and that special railway rates have to be paid on the spirit. The whole problem is now being tackled by the Benzol Producers' Association, a small committee of which, representative of the gas and coke industries, is considering such questions as specifications for quality, etc. It is understood, too, that the gasoline purveyors have been approached as to use being made of their existing facilities for distribution, and that the benzol producers consider a charge of approximately 2d. per gallon as appropriate for the concession. From what can be gathered, however, it is believed that the negotiations have fallen through owing to the petrol purveyors demanding more than twice that sum.

"It has often been argued that, owing to the ubiquity of gasworks, there should be no difficulty in arranging for innumerable depots for supply in all parts of the country, but while that is true in a sense, it must be remembered that it is exceptional for gasworks to take the process any further than the recovery of the crude spirit, which would be most undesirable as a fuel. This crude spirit is accordingly dispatched to the isolated centers at which plants for purification and rectification are found. Thus the double handling and transport have proved a costly item.

"In the past it has not been considered a commercial proposition for any but the largest gasworks to put down rectification plant, but the demand for a simple process of the kind has now led to the introduction of apparatus which can, without doubt, be profitably installed at all those gasworks employing 8000 tons of coal per annum and upwards. There are approximately three hundred works in England alone—exclusive of Wales and Scotland—which would fall within the limits named. As a supplement to these stations, there would be the coke-ovens in the North, and some provision could probably be made for increasing the poorer resources of the southern districts from them.

Every Gasworks a Depot

"Already a number of the miniature rectification plants, suitable for the small producers of the crude spirit, have been put on order. A plant of the kind, operated on the Wilton



Wilton benzol rectification plant

principle, is shown in the accompanying illustration. This plant appears to possess the merit of combining simplicity with moderate capital outlay. The crude benzol, recovered in the ordinary manner by means of the comparatively simple process of oil-washing, is, in the first instance, run into a crude still which merely consists of a small boiler to which is attached a simple column. Distillation is effected by means of steam coils, and the light products are distilled off, passing through a water-cooled condenser of ordinary construction from which, in the liquid state, they gravitate to the washer.

"In the larger motor spirit plants it is usual to arrange for secondary distillation, that is to say, the 'once-run' spirit is collected in a separate storage tank, and subjected to further distillation in the secondary still prior to undergoing the washing process. This secondary distillation, however, may be eliminated if the precaution be taken to work up the original crude spirit to a strength of from 70 to 80 per cent at 120 deg. Cent.

"One of the contingent advantages attached to the process of recovering crude benzol is the freedom gained from naphthalene troubles. The wash-oil with which the coal gas is treated, if of the correct composition, not only removes the light-boiling hydrocarbons, but the greater proportion of the naphthalene as well. Thus, benzol recovery offers a further very substantial inducement. It is for this reason that the residue which remains in the crude still of the motor-spirit plant consists of creosote oil highly charged with naphthalene. The economics of the process are such, however, that no product need now be regarded as waste, so that the creosote oil may be separated and sold as a by-product, while the naphthalene may also be refined, when it will command a good price. The creosote, of course, is derived from the original wash-oil employed, a small proportion of which invariably comes over with the crude spirit during primary distillation.

"As regards the light products obtained from the still of the motor-spirit plant, they contain such impurities as tar acids, tar bases, and sulphur compounds, which, of course, must be removed. For this purpose the distillate is treated with sulphuric acid and caustic soda. In the larger rectification plants agitation during washing is carried out by mechanical means, but, with the plant for the small gasworks, hand agitation is arranged for in order to avoid every possible complication. After the purification treatment the distillates are run by gravitation to the final rectification still, which consists of a dephlegmating column standing on a boiler. The contents of this final still are distilled off by means of steam, the distillates—representing the finished motor spirit—passing away through a water-cooled condenser, and thence to the underground storage tank."

Cammen Carsafe Load Governor

A SAFETY device which makes it impossible to start a motor truck when it is overloaded has been developed by the Cammen Laboratories, 42 West Thirty-ninth Street, New York. It consists of two parts, a registering device (Fig. 1) and a control device (Fig. 2). The registering device takes the place of the usual spring shackle and is a casting which has to be designed specially for each make of truck. The upper part, A, of the registering device is attached to the chassis and the lower part, B, carries the spring bolt, the two parts being hinged together at the right in Fig. 1. Part A carries an oil reservoir on which pressure is exerted by a plunger through a welded-in bronze-diaphragm. This pressure is transmitted to the Bourdon tube in gage C.

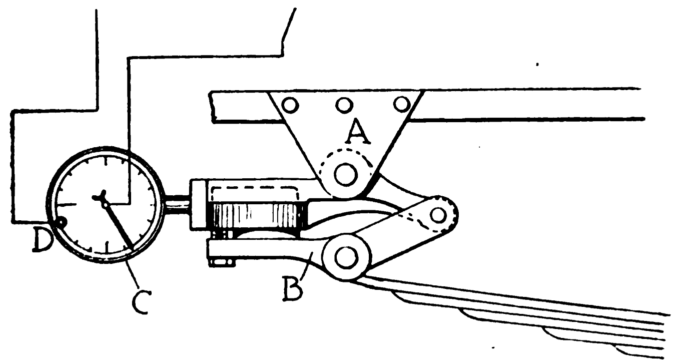


Fig. 1—Outline drawing of Cammen Carsafe.

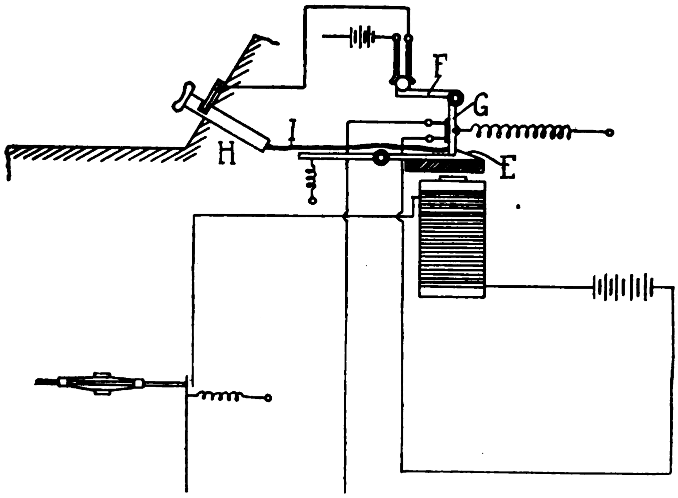

Fig. 2—Diagram of electrical connections.

The gage C is equipped with a circuit closing device so located that it is reached by the pointer when the load on the truck exceeds a safe limit. Let us say that the manufacturer or user desires to have a useful load of not more than 2000 lb. This, for a given truck, means that the load on each side of the rear axle should not exceed, say, 1600 lb. The circuit closing pin is then set at 200 lb., which is the load registered through the hydraulic transmission by the gage when the load on the truck is 1600 lb. for each side of the rear axle. It is generally sufficient to equip one side of the rear axle with a governor, the load being usually evenly distributed on the truck.

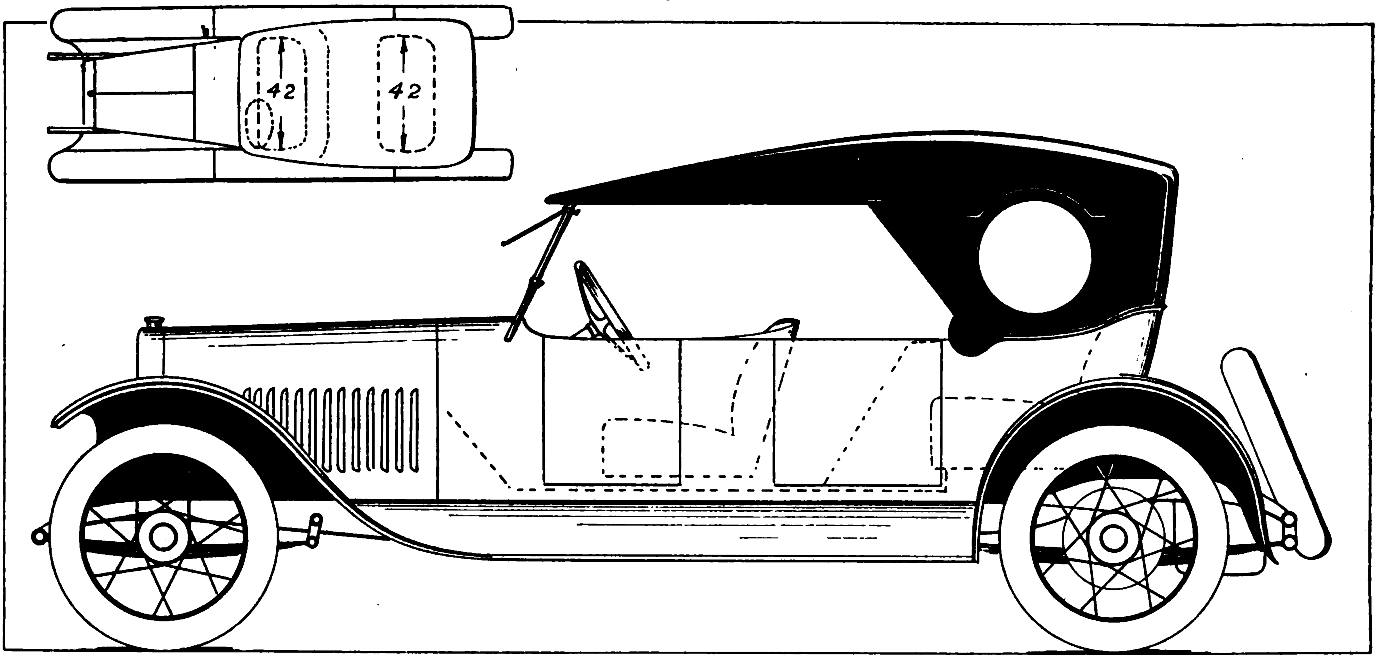
When the load exceeds the safe limit the pointer of the gage reaches the circuit pin D and thereby closes an electric circuit. This energizes an electromagnet (Fig. 2) and the latter then attracts its armature. This in its turn withdraws the catch, E, and permits the spring to pull over the bell crank, F, thereby opening the ignition circuit so that the engine cannot be run.

At the same time, however, the swinging out of the bell crank draws away the metal plate, G, against which press contact brushes, which opens the circuit around the electromagnet. In this way both the ignition circuit and the control circuit are automatically opened. The advantage of this is that the electromagnet may be made to carry quite a heavy current without exhausting the battery.

When the spring draws back the bell crank the latter strikes a bell (not shown in the drawing), which notifies the driver that the truck is overloaded.

Once the ignition circuit has been opened it will stay open until closed again by the driver. To do this the driver has to pull the rod, H, as far as it will go.

To prevent drivers from tampering with the governor the pull rod, H, which closes the ignition circuit, is made interlocking with the ignition switch. A slot is provided in the rod and the ignition circuit can be closed only when the switch feeds into this slot; but when the rod is in such a position that the ignition switch does feed into the slot, the cable, I, is quite loose and the bell crank cannot be held manually against the tension of the spring, which would be the only way to hold it if the truck was overloaded and the circuit through the electromagnet closed.



Close-coupled touring body with top having Victoria lines and windshield extension

A New Design Touring Body Top

Built on Lines of Victoria, with Windshield Extension and Drop Curtains Entirely Enclosing Rear Seat

By George J. Mercer

NUMERICALLY, the touring body is still the most favored of the body designs, although it has been predicted that it would be succeeded eventually by some type of closed body, because the occupants of the rear seat of open cars are subjected to the discomforts of dust when touring. But the touring body still holds its own and there have been many additions to make it suitable for all-year use, such as demountable and convertible tops as well as several forms of touring tops that have either a window or curtain arrangement that serves very well in keeping out the wind and rain.

The most popular type of touring body to-day is the close-coupled for four or five passengers. The chief advantage of this body type is that the rear seat is well forward of the axle, permitting a better arrangement for the comfort of the rear passengers. For example, with no auxiliary seats to be accounted for, a second windshield can be designed and fitted with an assurance that it can be made to work, because adequate space is available for operation.

Windshield with Drop Curtain

The design illustrated is an entirely new design of top that can be used with any close-coupled touring body. While it would be possible to make it demountable, far better results will be obtained if it is made permanent with the body at the time of construction. As it is intended to have the side windows drop down full length, pockets must be provided for them and the top must be well braced. A permanent ironed job is better than a take-on-and-off design.

This top has the lines of the well-known Victoria with the addition of an extension to the windshield. The design illustrated does not fold down, therefore no side braces with joints are needed and the windows can be made much larger. The rear lights are stationary.

The novel feature about this top is the windshield that with the aid of a drop curtain entirely closes in the rear seat. In Fig. 2 the shield and attached curtains are shown in position entirely closing up the front of the top. This glass is 21 in. long by 44 in. wide, and when in position has the same slant as the front line of the top. At the top are two spring pins that rest on the guide plates, on each of which there are two depressions. The pins rest in these depressions when in the two positions illustrated by dotted lines. In explaining this, we will start from shield position No. 1, which is also shown on the section. Position No. 2 is reached by releasing the shield from its fastening at the bottom and pushing it over as indicated by the arrows until the bottom is in line with the pocket into which it will eventually drop. In making this swing the shield is supported by the pins at the top which rest in the rear depressions in the guide plates.

When the shield is in this position, No. 2, a lip or plate on each side of the pocket is thrown up by revolving a knob, preventing the shield from swinging back again to the perpendicular. The shield is now resting loosely in the pocket opening. In order to provide room for getting in or out, the top of the shield is pushed along the guide plate until the pins engage in the depressions at the forward end of the plate. This brings the shield into the perpendicular position, No. 3. The shield may be used in any one of these positions. When not in use, it is first moved back to No. 2 position, and the pins drawn out of the depres-

sion in the plate by compressing the springs by means of the knobs on the frame for this purpose. The shield is then lowered into the pocket, position No. 4, where it is safely stored away and is flush with the top edge of the body.

When the shield is in use as in position No. 1, the rest of the space down to the floor is taken care of with a curtain, fastened to the back side of the shield with buttons and kept away from the knees by being fastened to each door, so that it has a tent shape that will be more comfortable. Above the shield the space is similarly enclosed by a short curtain fastened permanently to the top, and to the upper edge of the shield in the same manner as the lower curtain. This upper curtain is detached when the shield is dropped into the pocket.

This shield actually makes a combination body that is a novelty. In position Nos. 2 and 3 protection is assured from stormy winds and in position No. 1, with the drop curtain in place, the interior at the rear is virtually a closed body. When it is desired to put the shield away, it is dropped into the pocket at the rear of the front seat and carried with the minimum of strain on the body because the weight is low. It is out of sight and always ready for instant use.

There are similar top and combination shields used on the Pacific Coast, and are called California Tops. In all cases, however, they are an adaptation of the Demi-Limousine type and the shield is either slid up to the top and held there when not in use, or is parted in the center and turned inward toward the side when open for entrance or egress. Carrying the shield in the roof is very objectionable, as the additional weight is liable to weaken the top supports.

Wood and Aluminum Frame

The frame work of the top is of wood and quite stout. The round corners of the rear and the top are best formed of aluminum sheet and the imitation leather stretched over. A metal foundation of the rounded surfaces will insure a permanent shape and add to the durability of the goods, as all action set up by straining will be obviated. A drip molding is used on the sides to guide off the water from the top and a cod piece similar to that used on a real Victoria is formed at the base to add to the appearance. The top is lined on the under side, and as it will get a deal of dust, a tan or tan and gray shade of cloth will be best suited for wear, and slip cover should be used over all, or if unlined either painted wood finish or cane work are equally adaptable.

The side glass can be much larger and of different shape if desired, but that will be a matter of individual taste; as to the color of the top, any shade can be had and any one will give service provided the quality is there. Imitation leather for ordinary work and real leather for high class would be a sensible specification.

This design should be very acceptable to that considerable class of car users in the large cities that have favored Victoria tops both in season and out. It has enough of the Victoria to be of the same family, and in addition it possesses distinctive features that make it well adapted for town car use. The several positions on which the shield can be used will accommodate all kinds of weather, and in particular, will the closed-in position be a distinct adjunct.

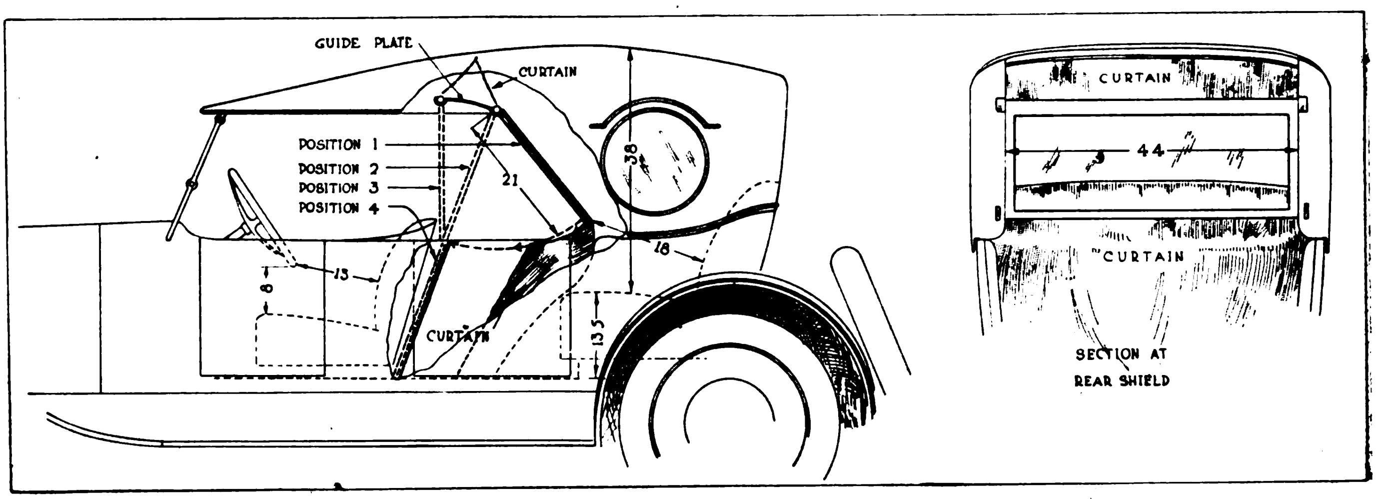
Should Appeal to Users of Victoria Top

The turning of a body of this type will be more elaborate than with the ordinary touring body. There should be a speaking tube or phone for communicating between the seats when the rear is closed. This can be easily carried on the roof. The trimmings can be a combination cloth and leather, the latter being entirely used for the driving seat.

The body design is similar to the accepted type seen at the recent shows. The seats are ample for comfort. The rear cushion is higher from the floor than the front, making it easier for a stout person to rise to a standing position than if the seat were low, and ample leg room is provided for all occasions. The extra tire is at the rear, where the weight is needed on most cars, especially when no passengers are carried on the back seat.

The dimensions of the body side light as well as size of doors, etc., are omitted in the drawings, but can be easily ascertained by measuring. One of the top dimensions, it is well to call attention to, is the distance between the lower edge of the shield and the turning of the back. This is 18 in. and is a very generous distance so as to remove any use of being packed in, when the shield is in position No. 1.

ACCORDING to the *American Gas Engineering Journal*, toluol being no longer used in large quantities for T. N. T., stocks are rapidly accumulating. A brisk demand for both benzol and toluol is predicted as a result of the establishment of the dyestuffs industry in this country. But there is no need to wait for that. Benzol, toluol, and solvent naphtha, now a drug in the market, can be sold mixed for motor-fuel. For that use it is worth 20 per cent more than gasoline.



Windshield and attached curtains entirely close front of top when in position

Continental Plant Layout Facilitates Production—II

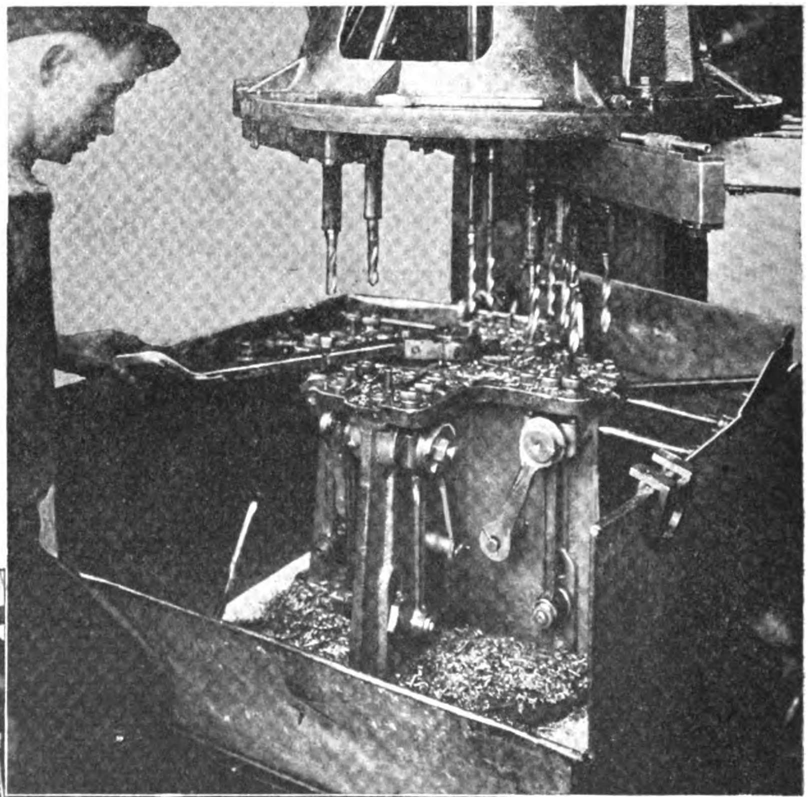
Engine Shipments Go Out on Same Tracks on Which Raw Parts Enter—True Progressive System Used

By J. Edward Schipper

ANOTHER important semi-automatic, compound machine in the piston department at the Continental plant is that which turns the pistons and grooves them. This machine is capable of turning and grooving 100 pistons per hour. The turning tool first descends, roughly turning the pistons to size. After this has done its work in a vertical direction, the groove cutters move over against the piston and cut the grooves to the proper depth. As soon as this depth has been reached the machine cuts off automatically. The pistons then pass on to be finish-turned and finish-grooved, ground and drilled for set screws, etc., finally entering the assembly department.

A machine in the connecting rod department which is of particular interest is that for drilling the holes for the connecting rod bolts in the crankshaft end of the rods. This machine, illustrated in Fig. 10, has ten spindles and a square table. The fixture accommodates eight rods at one time, six rods being actually machined at once, while the remaining two are being set up by the operator. The machine is capable of handling fifty-eight rods per hour. By the use of this machine, with the operator continually setting up two while the other operations are taking place, one man is able to handle this work on a single machine.

The oil pans and other deep drawn parts are made in the Continental factory, there being a special department for this purpose, where large presses are used. These



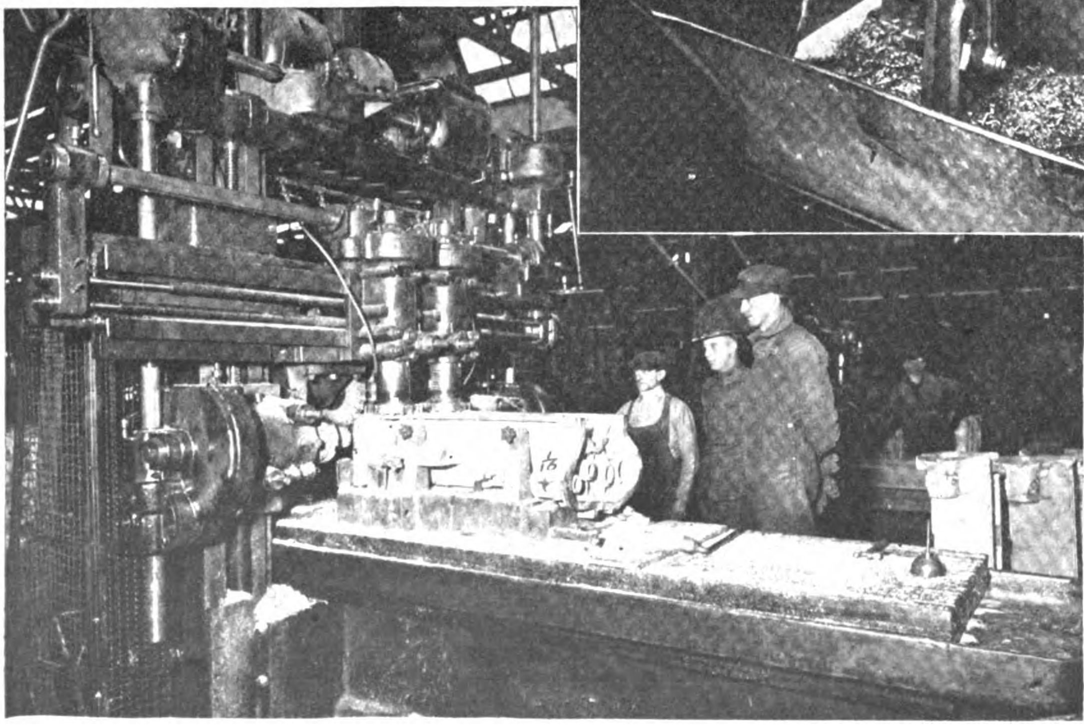


Fig. 10 — Fixture for drilling holes for connecting-rod bolts in crankshaft end of connecting-rods. This fixture accommodates eight rods at one time. Six rods are machined at once

Fig. 11—Machining operation on aluminum crankcase. Six surfaces are being machined at one time

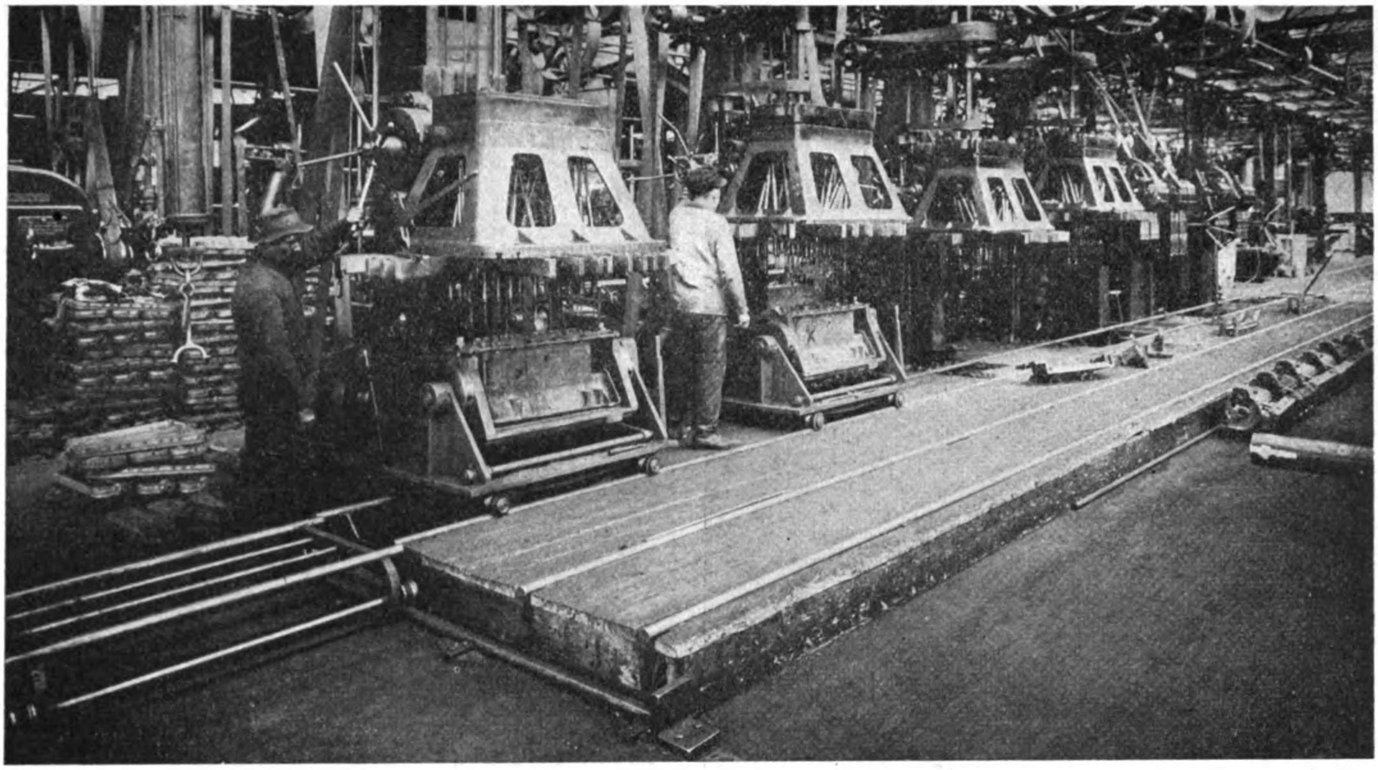

Fig. 12—Railroad fixture for drilling and reaming holes in cylinder block for valve stem and push rod guides. This set-up also takes care of valve seats and all holes and machine work related to the valve mechanism

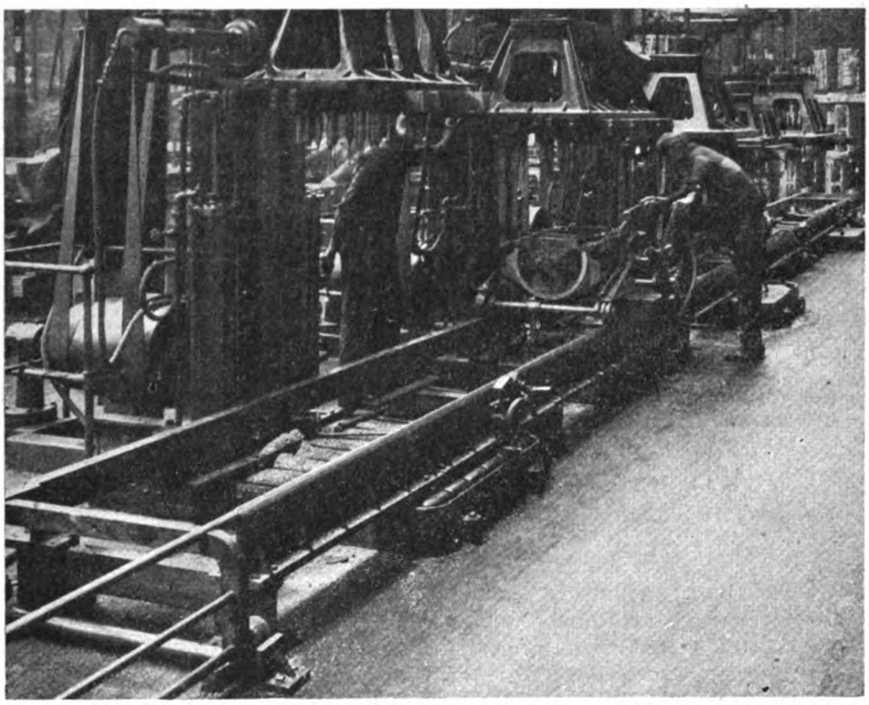

Fig. 13—Railroad fixture which drills all holes in aluminum crankcase. This fixture is operated by two men and requires approximately 3 min. for drilling all the holes

machines are the product of the E. W. Bliss Co. of Brooklyn, N. Y., and are capable of handling the deep drawing necessary for the oil pans in one operation.

In the crankcase departments a great variety of machinery and operations are necessary due to the six different models which are passing through. Some of the models have aluminum cases, and in one particular model, the Continental 7 W, the top part of the case is in unit with the cylinder casting. On the aluminum cases the greatest number of operations are performed, these being for the larger and more complex models. The milling machines for the aluminum case, shown in Fig. 11, are milling six surfaces at the same time. This is a long table machine and is the true starting point in manufacture on this case. The machine is capable of handling nine cases per hour. A high-speed miller is used for milling off the face of the crankcase to which the cylinders are bolted.

The drilling, reaming and tapping work on the aluminum cases is handled on a railroad-type drill with a single jig traveling along a rail. This railroad is a single-track type in which the jigs work along in one direction and is then rolled back. This railroad outfit is shown in Fig. 13. There are five sets of spindles to take care of the major part of the operations of this nature on the case.

A more complete type of railroad drill is used in connection with the cylinder manufacturing operations. This is shown in Fig. 12. It is a double track railway with a cross-over at each end, so that the carriers for the jigs can be moved back on the outside rail. There are eight operations on these jigs, and it takes a cylinder block of the type shown in the illustration about 20 min. to go the length of the railway. Four cylinder blocks are usually in process at a time. These spindles take care of practically all of the drilling, tapping, reaming and similar operations on the block, and the jigs are so arranged that

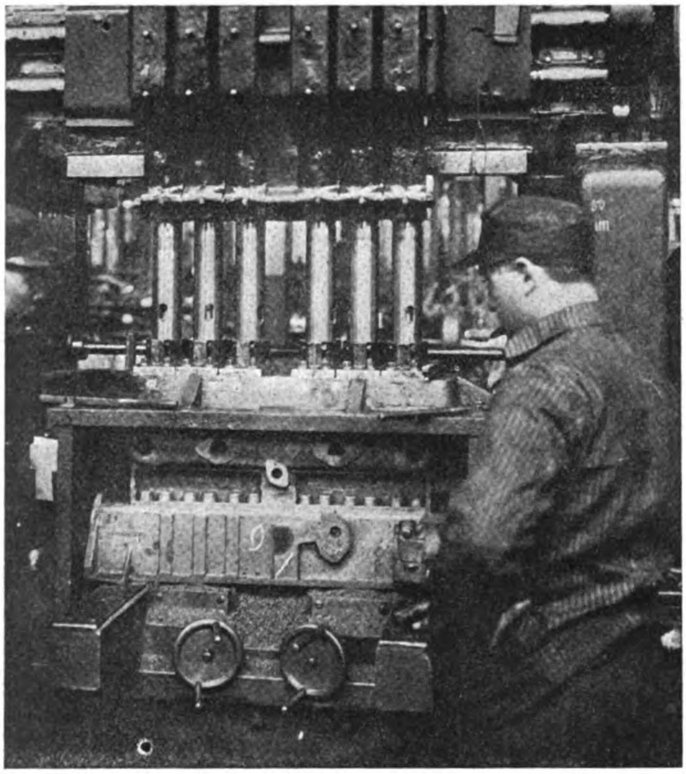

Fig. 14—Boring six cylinders at one operation

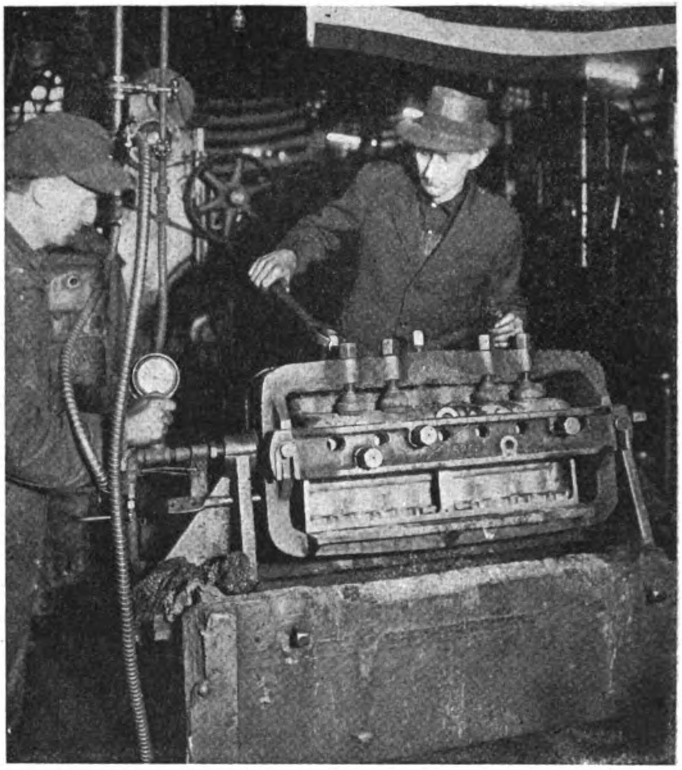

Fig. 15—One of the three water tests given each cylinder block. The first test is on the rough casting; second, after the cylinders are bored; third, after the cylinders are ground

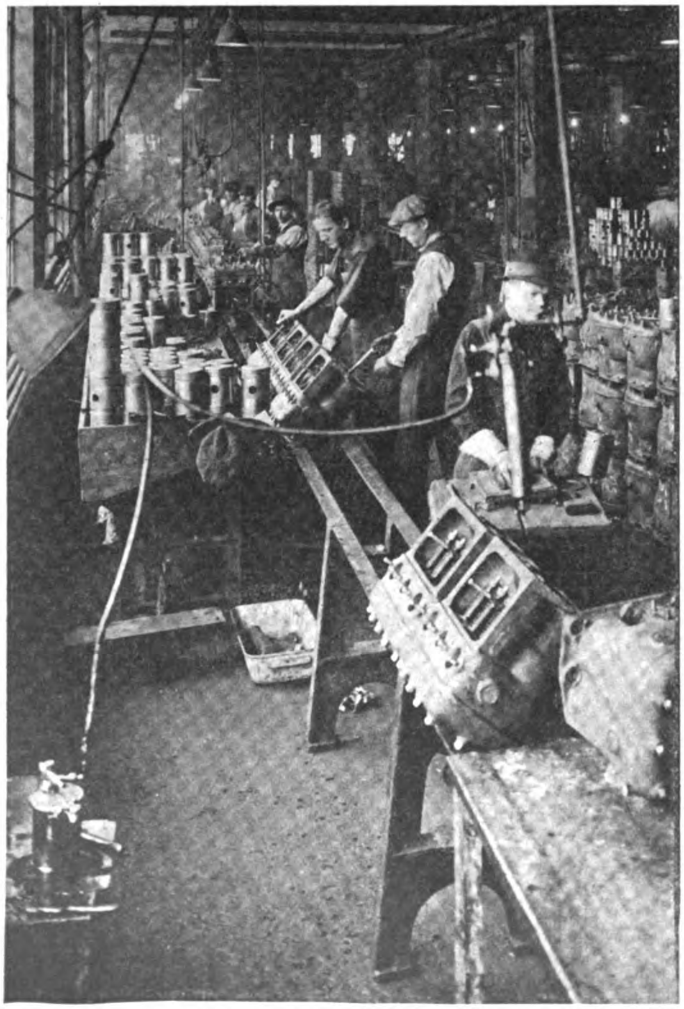

Fig. 16—Assembly department, showing racks tilted to the proper angle for fitting pistons to cylinders.

they can be turned over in the carriers to accommodate the block to the required position for the different operations.

In cylinder boring, all six are bored at the same time, this operation bringing the cylinders within 0.002 in. of the finish bore and preparing them for grinding. The boring machine, operating on six cylinders at the same time, is shown in Fig. 14. It takes about 30 min. to handle one six-cylinder block.

All of the manufactured parts go to the finished stockroom before they are started to the assembly line. This stockroom is on the opposite side of the manufacturing department from the raw stock, from which manufacture started. From here the parts are drawn at the proper point along the assembly line.

Assembly starts with the crankcase working along one line and the cylinder along the parallel one, the first operation being the passing of the castings through Blakeslee washing machines, where they are cleaned in hot alkaline solution. They are then air cleaned and the standard assembly operations started. The assembly starts along the back end of the building, and, as shown by the map herewith, works its way around three sides until it returns to the assembly and shipping departments, as shown on the diagram.

As the engine cylinder block progresses, the valve guides are pressed in and a set of piston rings selected so as to have a gap of 0.002 to 0.004 in. at the bottom and from 0.004 to 0.006 in. at the top. The cylinder head water jackets are given a water test, as illustrated in Fig. 15, so that leakage due to sand holes or other defects in the castings will be determined before the engine has passed along the assembly line. The gage in the illustration shows about 90 lb. pressure.

Along the assembly line the racks are all so arranged that the engine is at a convenient angle for the operator. Referring to Fig. 16, a sort of groove support is used

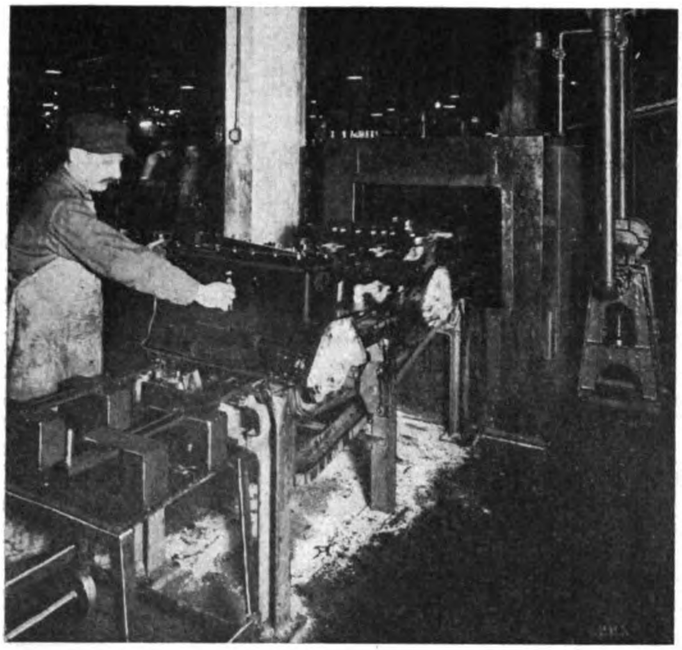

Fig. 17—Entrance to drying oven at Continental plant. Cylinders are fed through this oven on endless chain, the drying process being completed by the time the cylinder reaches the opposite side of the oven

for the blocks so that the operator can readily use his eyes in selecting the pistons, etc. Further along, the blocks will seem to be vertically upright where the operations are such as to require or make it advantageous to use the vertical support. The pistons are arranged in bins in the assembly department and are segregated in groups according to weights, so that all pistons which go into one engine weigh approximately the same. These groups of pistons are shown in the background of Fig. 16.

The valves are ground with a carborundum compound, after which the seats are cleaned with kerosene and the valves, caps, springs, etc., put in place. After the heads are put on, the cylinder blocks are painted, then passed through a gas drying oven, as shown in Fig. 17. The cylinders are fed to the drying oven on an endless chain, so timed that the drying process is complete by the time the cylinder reaches the opposite side of the oven. The smaller pieces have the paint sprayed on them in booths.

Final Assembly

After the painting has been completed the cylinder blocks move along to join the crankcase, upon which assembly has also been proceeding at the same time. When these parts are joined there is an overhead conveyor which carries the practically assembled engine over to the second side of the building, along which it moves on its way to the testing department. Here the final work is done on the assembly, the camshafts, manifolds, oil pans, etc., being put on, after which the tappets are adjusted, the timing gear cases fitted and all the minor accessories put in place, until the engine is complete and ready to be belted in.

Engines in practically completed state are shown in Fig. 18. These are just receiving their final assembly touches and are on their way to the testing department. The engines are run under outside power for 3 hr. at a speed of 150 r.p.m. They are then picked up by an overhead crane and set down on one of the testing blocks. Here they are run for 3 hr. under their own power, after which they are taken down and inspected and moved to a set of final test blocks for at least 2 hr. or until they have passed the final inspector's rigid test, at an average speed of about 900 r.p.m. The final testing room is shown in Fig. 19.

When they have satisfactorily passed their final test they are picked up and taken to the shipping department or are placed on the traveling chain, or endless belt shown at the right of Fig. 19. This carries them to the shipping room, seen in the rear in Fig. 23, and which is shown in a closer view in Fig. 20. Thus there are three

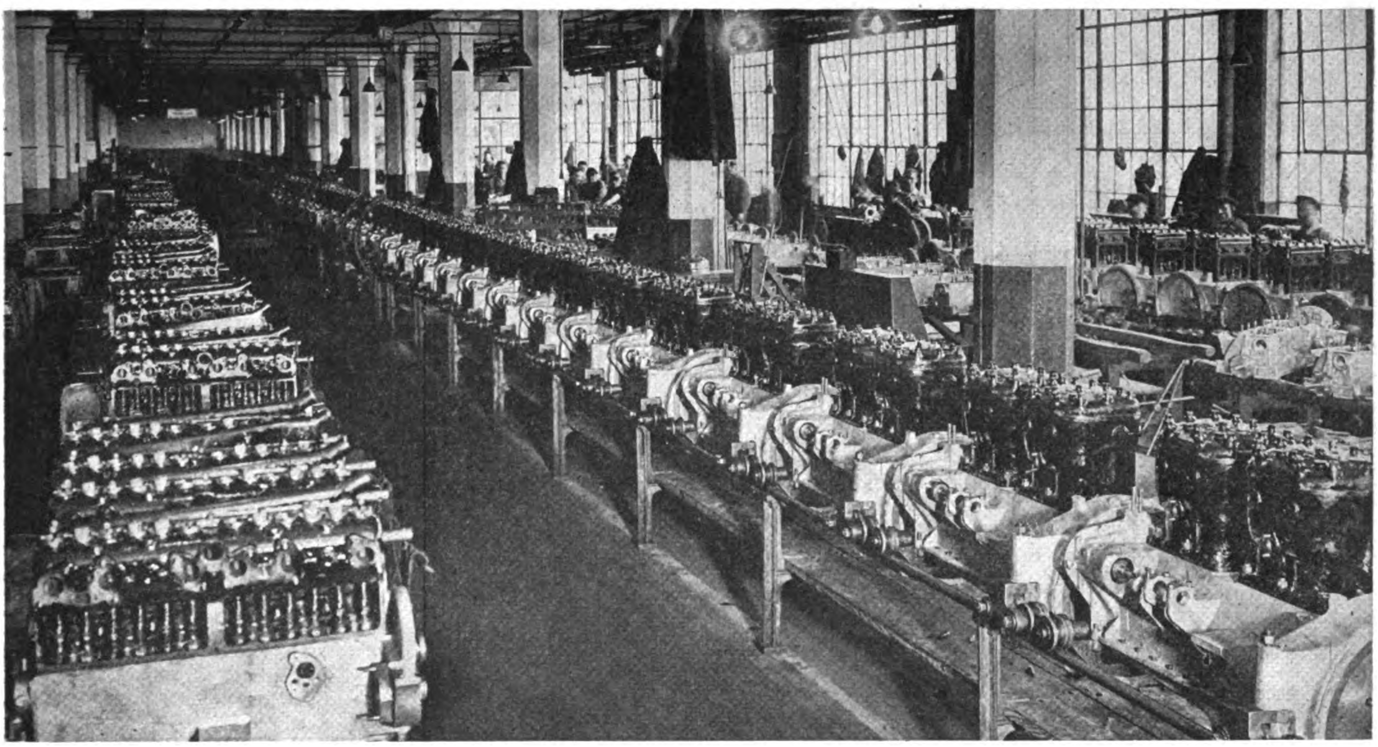

Fig. 18—Partial view of Continental final assembly department. This shows long lines of engines on their way to the testing department

Continental Block Testing Department

Fig. 19—This illustration shows the electric starters on tracks between test block and the endless belt on upper right which is controlled from and carries engines direct to shipping platform

parts to the Continental test: First, the running in, in which they are driven by external power; second, the first test run where they run under their own power; and, third, the final test before shipping. Should anything develop at the final test, the engines are taken down, adjusted and corrected, and again tested until they are satisfactory. It takes three overhead cranes to move the engines around the various parts of the test department, and, in addition, the endless belt carries them to the shipping department from the test room.

The shipping department parallels the track upon which the raw material first came in, the shipping platform being on the opposite side of the track from the receiving platform. Thus the engines in passing through the Continental factory have completed a circuit and, while never once retracing their path, have been progressively manufactured and assembled from start to finish.

This layout, which was developed during the time the company was engaged in the manufacture of Class B Government trucks, is being continually perfected and is resulting in increasing plant efficiency.

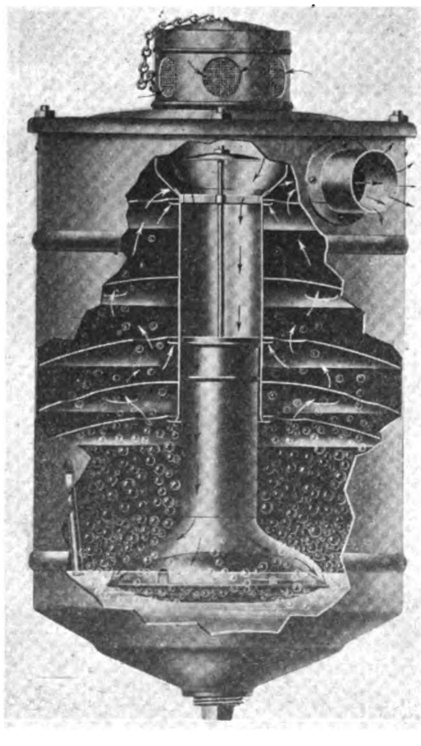
R. W. Parrett Water-Type Air Cleaner

ROSS-WORTHAM CO., McCormick Building, Chicago, is manufacturing the Parrett water-type air cleaner herewith illustrated. Air enters at the top and is drawn downward through the central tube. The lower half of this tube is flared out "bell shaped" and is supported on a metal float of elliptical cross section slightly smaller in diameter than the bottom of the bell. The air passes through the narrow ring-shaped opening between the bell and the float at very high velocity. On account of the shape of the air stream no large air bubbles can pass through the water, and on account of the high velocity of the air the heavy dust particles are thrown directly into the water. The air itself is so thoroughly mixed with the foaming water that the lighter dust particles are also trapped and the mud settles to the bottom of the tank, whence it can be drained off daily, or as often as is necessary.

This thorough mixing of the air and foaming water settles the dust, but the next big problem is to separate the water particles from the air before it leaves the washer. A series of baffle plates is claimed to do this very effectively, and experience has shown that not over one quart of water is evaporated in an ordinary day's operation.



The restriction of the air flow through the washer is practically negligible, being about 2 in. of water under full engine load, which is very small compared with the drop through the carbureter. Tests are said to have shown that in spite of the slight frictional resistance, engines have developed slightly more power with the washer.

An overflow is provided to limit the high water level and an indicating disc attached to the float tube not only shows the amount of water in the tank, but also automatically shuts off the air inlet when the water level reaches the low point.

While high efficiency is claimed for this air washer, the makers wish to call attention to the fact that the washer can be placed to better advantage than in the very dustiest part of the tractor and that all air piping from the washer to the hot air stove and thence to the carbureter should be absolutely tight.

The need of air cleaners is now fully recognized and practically every tractor carries one.

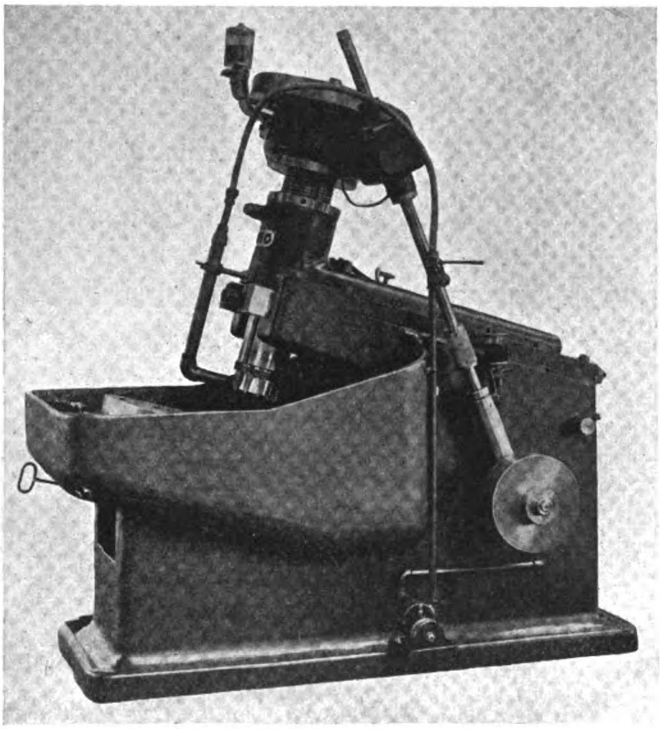
The Ohio Tilted Rotary

A Heavy Duty Machine Tool of a New Type Designed to Reduce Idling Time and to Insure the Best Cutting Conditions

THERE are certain recognized disadvantages in conventional milling machines that have limited their use in manufacturing operations in the past. These may be classified as follows:

1. Idle time between cuts.
2. Lack of rigidity due to the multiplicity of parts required when great versatility is aimed at in a single machine.
3. Insufficient lubricant for cooling cutters.

The Ohio Tilted Rotary is a continuous production milling machine designed with complete disregard for precedent. The designer's object evidently has been the production of a machine sufficiently rigid and powerful to overcome the limitations enumerated above. The different phases of the problem were studied separately and the features of construction and application of the new machine can best be studied by analyzing it from these three standpoints.

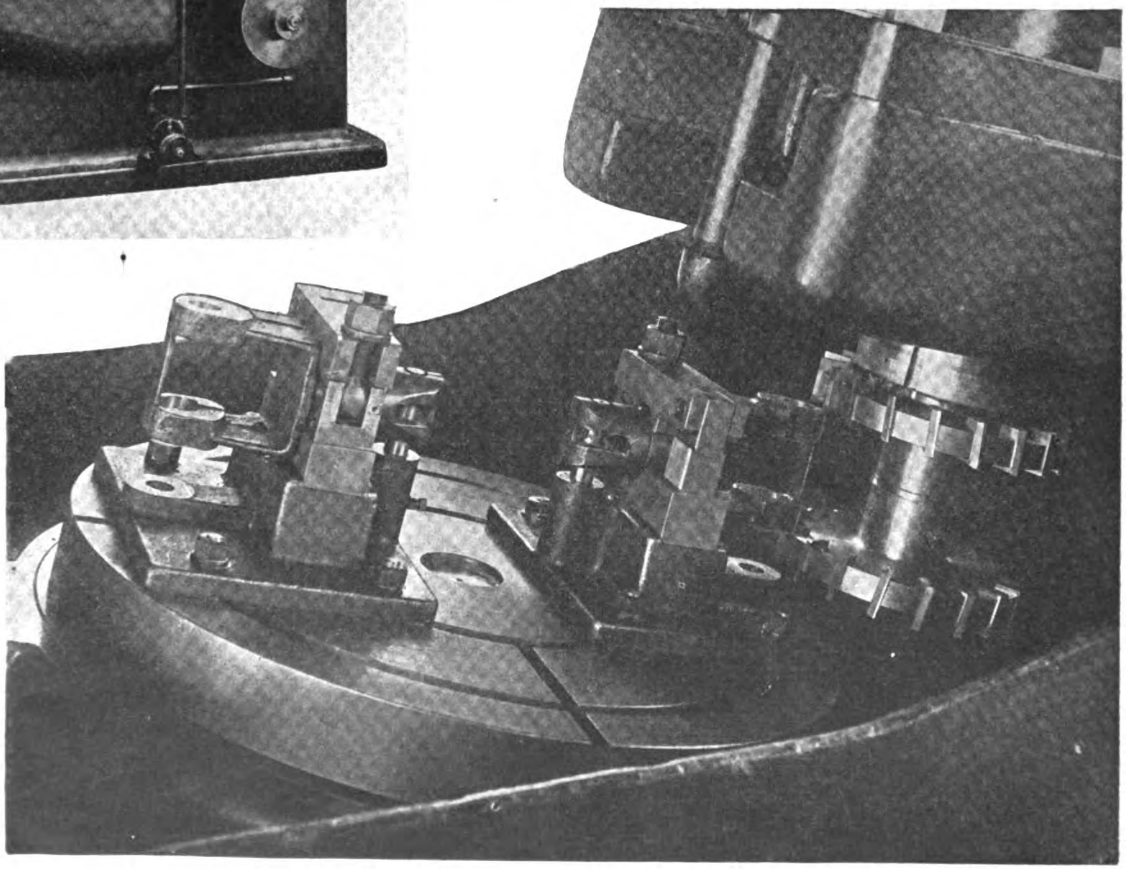


Side view of the Ohio tilting rotary, showing coolant circulating pump, drive of cutter head, etc.

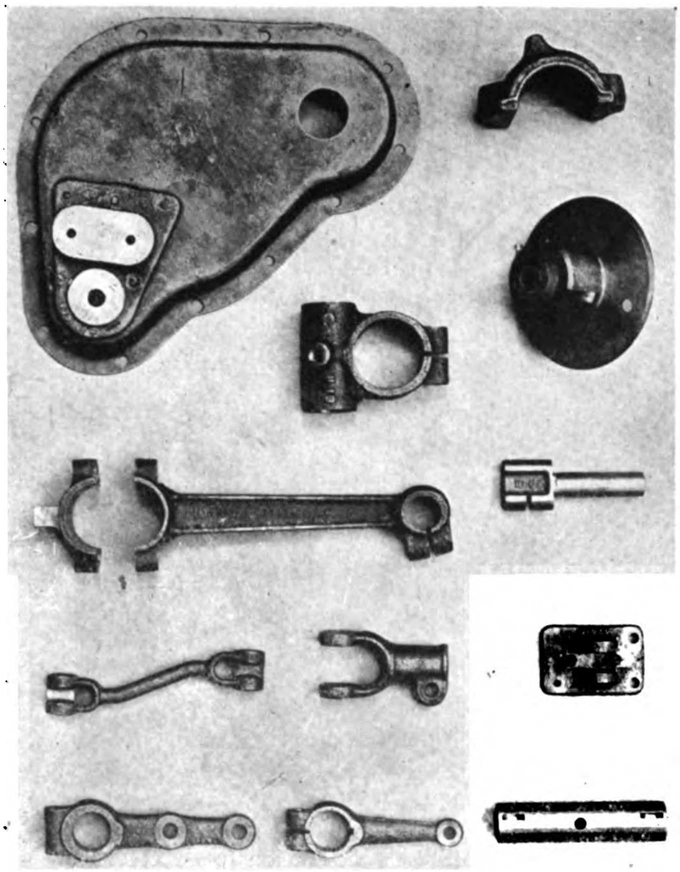
Idle Time Between Cuts

The time spent in returning the ordinary sliding table, removing the finished work, clamping the new piece in the fixture and again bringing the cutter to the working position is non-productive time. Continuous milling eliminates this time loss, with a consequent increase in the output per hour. This is accomplished on the Ohio Tilted Rotary by a rotary table which carries the work to the cutting position, and on which work is being replaced at the opposite side during the cutting operation. This continuous operation of the machine not only eliminates loss of time, but also sets the pace for the loading operation and results in a uniform output over a given period of operation.

The cutter can be held in a fixed position and the table



Straddle milling an automotive part in the Ohio tilting rotary



Samples of automotive parts that can be advantageously finished in the Ohio rotary

rotated continuously by automatic feed for continuous milling, or the cutter may be reciprocated radially in combination with an intermittent motion of the table, controlled by an indexing mechanism. This indexing mechanism is capable of from 2 to 72 divisions, and the table revolves rapidly between divisions so as to reduce the idle time.

By feeding the cutter radially over the surface of the work the loss of time between milling of the surfaces is avoided on such jobs as cannot be compactly spaced. Other advantages gained are that non-productive time of cutter approach is avoided, that the cutter travels the shortest possible distance, that two or more simple fixtures may be used instead of one large fixture, and that the machine will work efficiently on small lots.

Rigidity

Rigidity is secured by using a minimum number of parts and making these of massive construction. The body of the machine is cast in one piece, which in its general lines resembles a punch press or a shear. The working surface of the table and the cutter spindle are both contained in this massive casting, and the possibility of deformation under load is therefore reduced to a minimum. The body of the machine is directly under the circular table. There is no overhang on any part of the machine, the ram bearings being extended in front so that even in the advanced position of the cutters the full length of the ram is effective.

A worm wheel of 28 in. pitch diameter, driven by a worm of 1¼-in. pitch and 4-in. diameter, drives the circular table. The worm wheel is located as close to the table surface as the taper table bearing will permit, and is bolted and pinned to the table at the end of the bearing, the central stud merely serving as a means of aligning the worm wheel and table. This table bearing comprises 475 sq. in. of bearing surface, and this surface is straight. The ram bearing has a total surface of 1000 sq. in. and three gibs are provided for adjustment in all directions.

The spindle carries a No. 16 B & S taper and the cutters are positively driven by means of a clutch in the end of the spindle. A flywheel is mounted on the other end of the spindle to steady the motion of the cutter as it is driven through the work. This feature, in connection with the massive construction of the machine, tends to eliminate vibration, which latter is detrimental to the permanence of the cutting end of the tool.

Provisions for Cooling Cutters

Coolant is raised by means of a pump (circulating 35 gal. per min.) several feet above the surface of the table, and is then expanded into a large pipe so that it falls on the cutter and work under practically no pressure. This system prevents splashing that would be caused by a high velocity of flow, and the coolant is carried around by the revolving cutters so that it passes over the cutting edges during their idle travel.

The tilting table gives a low, pocket-like cutting position, and a greater flow of lubricant may be used without splashing than would be possible on a horizontal table. The flow washes practically all the chips away from the work, the tilting table assisting in condensing them in the space provided in the base of the machine.

The tilting table makes it possible to use an auxiliary pan so that the cutters could be run entirely beneath the surface of the coolant, and the work emerge from it at the loading position. The coolant drains from the chips into the base of the machine, which forms a reservoir of 60-gal. capacity. This "sub-surface" cutting is not provided for in the regular equipment, however.

General Description of Machine

The machine is driven by a 4-in. belt from a line or jack shaft on top of the machine. Power for driving the spindle is transmitted from the pulley, through mitre gears to an intermediate shaft which connects with the first change gear shaft in the speed box by means of a second pair of mitre gears. A single pair of change gears connect the first and second change gear shafts. "Pick-off" gears are used on the two shafts to vary the spindle speeds. A bevel pinion on the second change gear shaft meshes with a bevel gear on the spindle.

The intermediate shaft is splined at the upper end, at the pulley shaft and first intermediate shaft trunnion, to allow reciprocation of the ram.

The intermediate shaft is made in two sections which are joined by means of a coupling. By uncoupling and turning the first change gear shaft through half a revolution the opposite end of the upper half of the intermediate shaft couples with the lower section. This reverses the direction of rotation of the spindle and allows the use of either right or left-hand face mills as desired.

The "pick-off" change gears provide 30 spindle speeds, using 30 (15 pairs) change gears. Ball bearings are used in the driving mechanism wherever practical.

The spindle is carried in a sleeve, on the upper end of which is the speed box casting. The lower spindle bearing is 4½ in. in diameter and runs in a phosphor bronze bushing. The upper spindle bearing is a radio-thrust ball bearing. A clutch in the end of the spindle provides for positive driving of arbors, and the spindle is bored for a No. 16 B & S taper shank.

A flywheel weighing 250 lb. is mounted on the upper end of the spindle. The spindle sleeve is adjustable vertically by means of a graduated collar engaging with a coarse thread on the spindle sleeve. The spindle sleeve

is clamped firmly in the split barrel of the ram after adjustment.

The ram is fed radially over the surface of the table by means of a cam. The cam feeds the ram forward slowly during the cutting operation and allows it to drop back rapidly at the end of the stroke. The relative radial travel of the ram is made adjustable by means of a slide mounted under the ram. The slide is operated from the side of the ram by means of a ball crank lever and is clamped by means of a knurled knob. A double row ball bearing serves as a cam roller.

The pulley shaft extends through the machine and drives the feed box mechanism. Operations of the feed box are controlled by a push rod extending along the side of the machine to within reach of the operator.

The camshaft is driven by a worm and worm wheel in the feed box. A four-gear feed change mechanism regulates the feed of the table when the continuous table motion is used, or the rate of revolution of the cam when the indexing mechanism is used. The cutting feeds, therefore, are established by the ratio of these change gears. "Pick-off" gears are used to obtain these ratios.

The entire indexing mechanism and cam may be omitted for a machine on which only the continuous feeding table is desired, or the indexing mechanism may be added to a continuous feeding machine at any time.

It should be noted that the feed change gears regulate the rate of travel of the ram, and the throw of the cam regulates the length of travel of the ram.

A crank operated shaft is provided so that the feed mechanism may be operated by hand when setting up or trying out a job. A lever is also provided for tripping the index mechanism.

The cam is driven by jaw clutch teeth and may be quickly removed by withdrawing the camshaft.

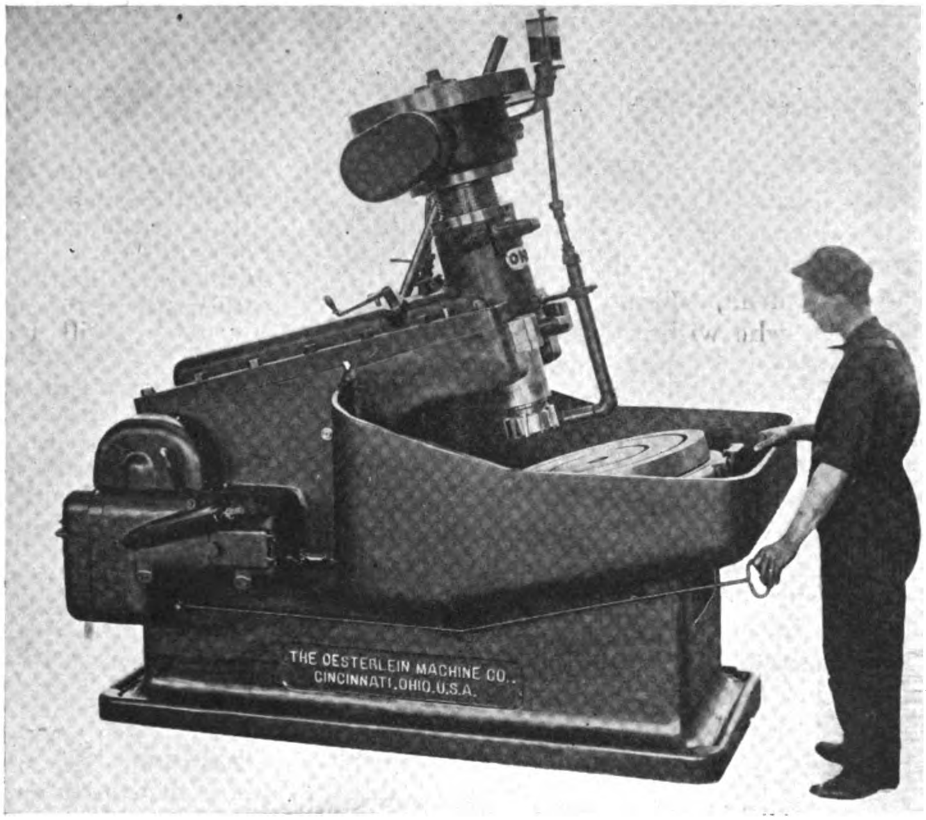
The rotary table is set at an angle of 15 deg. and is 30 in. in diameter. It is driven by a hardened worm and a worm wheel.

A large central distribution oiler on the speed box provides for speed box and spindle requirements, and a similar oiler lubricates the pulley shaft. A central oiling point located at the top of the ram provides distribution to the ram slide, and similar provisions are made for the feed box mechanism and for the table bearings.

Recording wattmeter tests show that the machine running at high speed without cut consumes 1½ kw. of power, including the motor and the lubricant pump. The pump alone delivering full stream requires about ½ kw

Applications of the Machine

The mechanism necessary to provide for quick adjustment of the machine has been omitted, so that simplicity of construction and rigidity may be obtained. The machine is, therefore, a production miller, applicable in a practical way only to such jobs that by reason of the quantity justify the necessary set-up time.



Ohio tilted rotary and operator

The machine when used as an indexing machine permits of the use of two or more simple fixtures instead of a large one-piece fixture holding many pieces. This feature greatly broadens the field of application and reduces the expense of tooling. By feeding the cutter radially over the surface of the table the advantage is gained that the table is indexing while the cutter drops back to the starting position, and the radial travel eliminates cutter approach and also the non-productive time spent in passing from one piece to another on the continuous feeding machine.

The Indexing Table

The indexing table in connection with a radially feeding cutter permits of dropping a cutter into the work, and such operations as Woodruff key-seating are possible with the indexing system, whereas they are impossible on a continuous feeding machine.

Other applications of the machine when used as an indexing miller are: Cutting a keyway along the length of a shaft or stud; facing off bosses or other surfaces in a plane that is not accessible to a stationary cutter and a continuous rotary table feed, and the milling of small surfaces on large pieces, where the loss of idle continuous feeding time would more than offset the gain of continuous loading.

The adaptability of both the continous rotary and indexing combinations permits of the advantageous use of the machine in shops where several widely varying operations are performed and the lots are comparatively small. As an example of the above, in a shop producing 200 warehouse trucks per month, six pieces requiring nine operations entering into the construction of the machine may be performed with equal facility on either the continuous feeding or the indexing combination of the Ohio Tilted Rotary.

Looking Forward—The Engineering Issue

ATTENTION is called to the Engineering Issue of AUTOMOTIVE INDUSTRIES, which will be issued June 12. The material for this special number is well in hand, and it will become an important part of the data of the engineer who wishes to be fully informed of developments in the automotive field.

The AUTOMOTIVE INDUSTRIES' staff has searched the field and special articles, prepared by men connected with different branches of the industry, have been obtained.

The tractor field, which is developing at a marvelous rate, will be discussed from every angle. In addition to several articles on the principles of design there will be an article discussing tractor features from the user's standpoint.

Trucks are presented from similar viewpoints. The question of loading and unloading, always a vital one in the use of the vehicle, is given special attention. The effect of truck design on sales is an interesting question.

The airplane industry has before it some great primary problems. These also are presented by the men who must be depended upon to reach a satisfactory conclusion.

Trends in automobile design, both in this country and abroad, will receive attention, and the articles under this heading will prove both timely and interesting.

The new factors in the labor situation, recently a strong feature of AUTOMOTIVE INDUSTRIES, will be reviewed. The progress made toward the solution of these problems will be presented in an informative and helpful article.

Foreign trade is rapidly developing for the automotive industry, and every factory going into export production now is confronted with new problems in this connection. You will find some of them treated in the Engineering Issue.

Finance, tariff, production and other important phases of the manufacture of automotive products are all covered in this Engineering Issue. They form the link that connects the laboratory and factory with the executive departments.

The war led to much productive research on materials and fuels. These fields are changing, and reports from investigations made for war purposes are becoming available for publication. Some of these reports will be found in the Engineering Issue and they will throw much light on the progress of the industry.

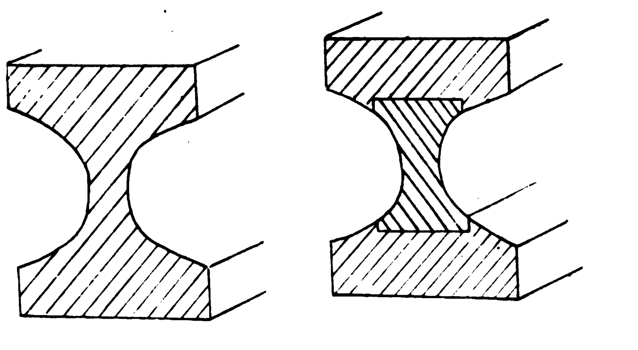
Three-Piece Wing Beams as Strong as Solid Beams

BENDING tests conducted upon DH-4 I-beams built up of three parts (two flanges and a web) and solid beams of the same cross section indicate that the two types have practically the same strength.

Ten test beams of each type were constructed as shown in the accompanying sketch. The specimens were made of closely matched material, the solid beams and the flanges of the 3-piece beams being cut side by side from planks of clear Sitka spruce. Cold casein silicate glue was used in making the built-up beams.

Under 4-point loading, which simulates the actual loading in service, the average maximum loads sustained by the two types were nearly the same. The difference was in favor of the built-up beams, but was too slight to be significant.

The construction of I-beams of 3 pieces as suggested offers certain obvious advantages. It permits the utilization of cross-grained material in the web, and since smaller pieces are required than in the case of the 1-piece I-beam, it is probable that from two to four times as many beams could be produced from a given amount of lumber.

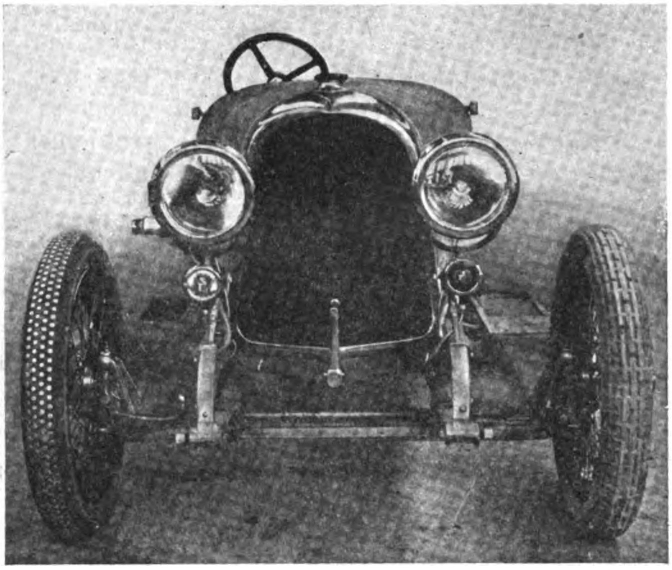


Use of German Army Trucks During the Transition Period

THE German Government "Reichsverwertungsamt" (Reconstruction department) has just organized three new sub-departments with a view to the utilization of returned army trucks, etc., for transit purposes in the country, to help out the situation owing to railway traffic difficulties. The first of these deals with the sale of trucks, tires, etc., the second is concerned with the control and release of available vehicles and the distribution of new tires. The latter, however, are only available in very limited numbers—much less than necessary to meet requirements. There are branches of these organizations in various towns. The third section deals purely with transport matters, and is described as a "general utility undertaking."

Voisin's Initial Chassis

By W. F. Bradley



Head-on view of the Voisin

PARIS, May 1—Gabriel Voisin, pioneer airplane builder, has entered the automobile industry with a high-class 4-cylinder, 30-hp. Knight engine car. The Voisin, which will be built in small volume with a view to the highest possible quality, has a number of distinctive, detail features.

The cylinders, which are a block casting of 95 x 140 mm. (3.5 x 5.5 in.), have a detachable cover over the head completely enclosing the spark plugs. The magneto is driven from a cross-shaft, which also operates the water pump, and the ignition wires are taken to the plugs through a passage cast in the cylinder block. When the fan is removed no working parts are visible.

Although a comparatively small engine, the crankshaft is carried in five bearings, the main bearings having a substantial length of 3.1 in. Lubrication is under pressure to the main bearings and by means of constant level troughs to the connecting rod bearings. In addition to this main lubricating system, there is a supplementary oil feed to a point around the exhaust ports. This supplementary supply is only opened when the throttle is in full open position. Further, the pressure on the supplementary line is reduced by means of a reducing valve in relation to the pressure on the main line. It is found that the pressure suitable for the main bearings is altogether too high for delivery to the sleeves.

In general features of design, the engine follows the usual Knight practice. It should be pointed out, however, that the Knight patents are no longer valid in France. The decision of the courts rendered just before the outbreak of war held that the Rolland-Pilain sleeve valve engine constituted a priority.

In designing the Voisin, considerable attention has been paid to those details which interest the man who spends a considerable amount of time on the road; for instance, the number of sizes of bolts and nuts has been reduced to three throughout the car. The mechanism has been made as self-lubricating as possible. The design is simple, and wherever possible parts have been rounded off in order that dust and dirt may not collect.

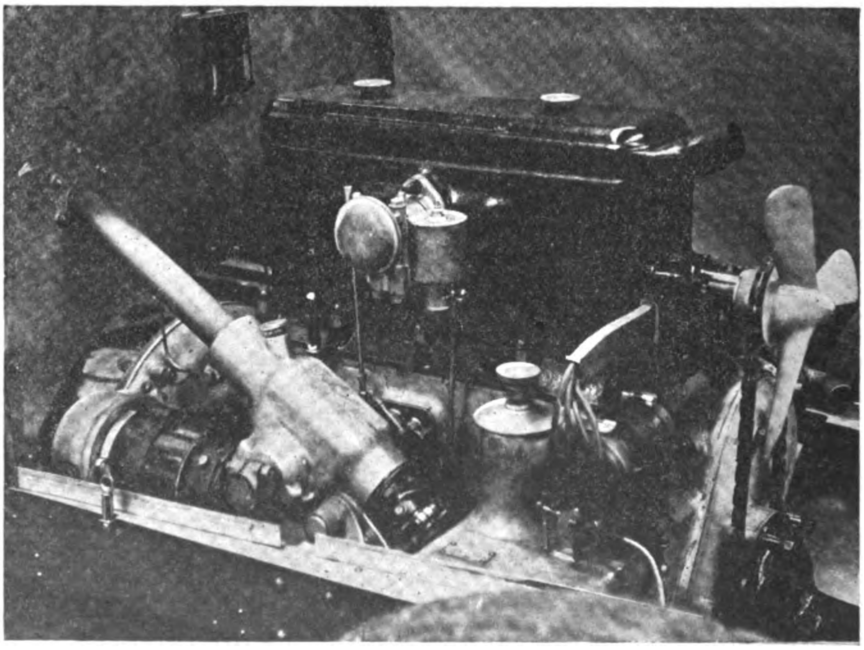
The carbureter is a Zenith horizontal, fed with gasoline by means of the vacuum system. On the right-hand forward crankcase hanger there is a combined oil filler and breather. When this is swung back to allow oil to be poured in the base chamber, a level cock is opened so that if the engine is filled with oil in the dark it is impossible to raise the level above the required limit. At the same time there is an oil level indicator on the side of the engine base chamber.

Water Pump

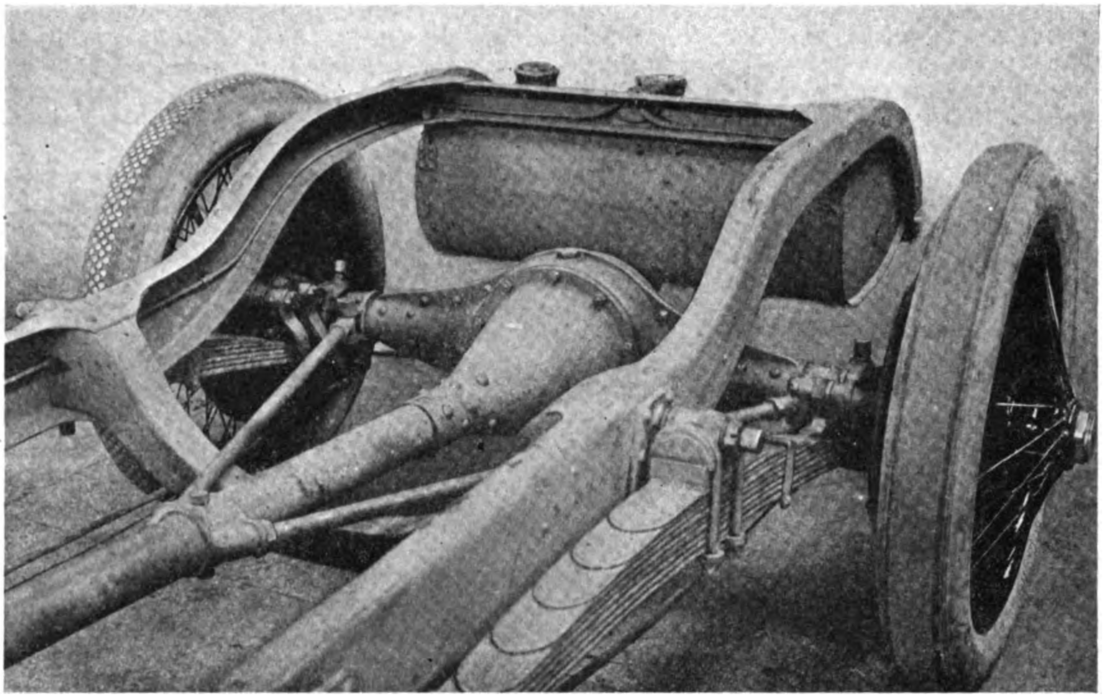
The water pump has a gland kept tight by an internal spring. A case aluminum three-blade fan is fitted, but the claim is made that this is not required except for work in hot cities. The fan and bracket are demountable and a small metal plate covers up the fan attachment.

Aluminum pistons are made use of with forged I-section connecting rods, the wrist pins moving in bronze bushings fixed in the pistons.

A two-unit lighting and starting set is provided, the generator being on the left side, just ahead of the flywheel housing, and the starter on the opposite side, immediately behind the starting gearbox. Unit construction of engine and gearbox with three-point attachment to the frame is adopted. The clutch is a plate type with Ferodo lining.



Carbureter side



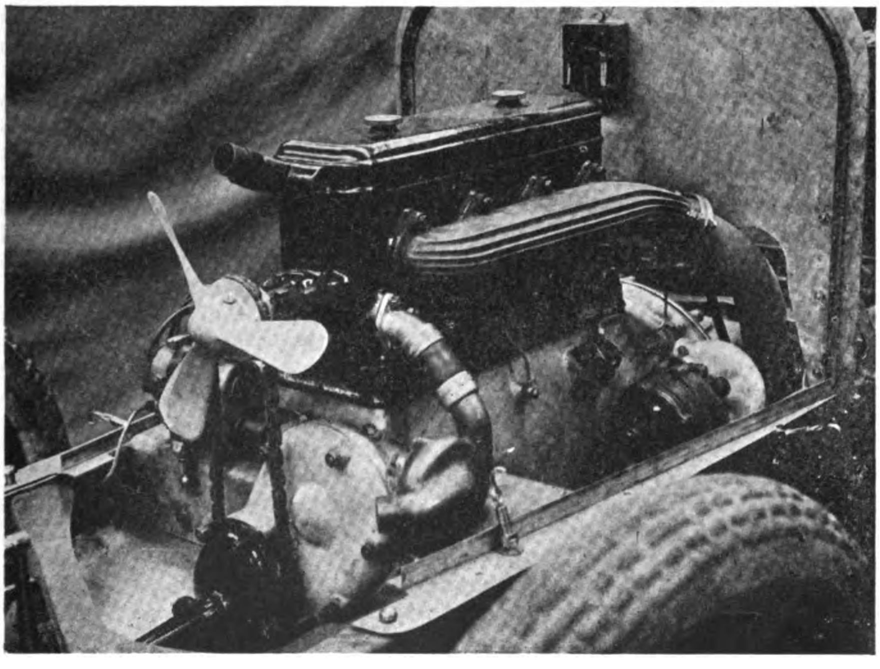
Rear axle construction

A particularity of the gearbox is that it is cast in one piece, with a detachable plate on the right side. This plate carries the change-speed lever, which consequently is quite independent of the frame members, and it also serves to insert the gear shafts. There are oil collectors immediately above the gearbox bearings, and after lubricating the rear bearing the oil flows to the forward universal joint.

The rear axle is of the banjo-type, formed of two forgings, riveted and welded together. To the forward face of the axle housing is bolted the casing carrying the driving pinion, and riveted to this casing is the tube surrounding the propeller shaft. There is diagonal bracing from the two ends of the axle to a collar on the propeller shaft housing. On the rear of the axle housing there is a light aluminum inspection cover.

Springs are long, cantilever type, pivoted to a bracket on the side frame member and attached to the axle by means of a spherical instead of the usual cylindrical attachment. Although a lubricator is provided for the collars receiving the rear ends of the two springs, any oil which leaks along the propeller shaft is carried to this collar and thus provides additional lubrication. Both sets of brakes are on the rear wheel drums, but instead of being set side by side, as is the usual European practice, they are mounted concentrically. The brake shoes are lined with ferodo, and instead of the operating cams coming into direct contact with the shoes, they attack a hardened adjustable nut on the latter. This gives an additional brake adjustment, and also enables the brake cam to operate at a correct angle at all times.

Right-hand steering is adopted, and a polished aluminum dashboard with a false front for carrying the instruments is provided. Standard equipment comprises either detachable wire wheels or the Michelin steel-disk wheels. All chassis are built to receive custom bodies, but the chassis are turned out complete with wheels, tires, wheel carrier, electric lighting and starting, head, side and tail lights.



Exhaust side

—

Italy's Needs in Machine Tools

THE provision of machine tools for their expanding industries after the war is exercising the minds of prominent Italians. One-tenth of these imports before the war was supplied by England, three-tenths by America, and six-tenths by Germany. The last named country will, however, cease to count among Italy's suppliers, and her requirements will have to be met elsewhere. To this end, says *Engineering*, a company was recently formed at Milan which, pending the time when Italy is able to provide for her own wants, will control the business of machine tool imports, among which agricultural motors and machinery take a leading place.

Savings Facilities for Employees Make for Stability of Organization

Plan Must Be Without Taint of Paternalism and Workers Must Have the Freedom of Dealing at Will with Regularly Recognized Financial Institutions—Real Property Interest Serves to Stabilize the Interest in the Work and in the Community

By Harry Tipper

IT requires only a cursory comparison of the present day attitude toward the workers with the attitude of ten or fifteen years ago to determine the advance which has been made in the understanding of the effect which the physical surroundings of the worker have upon his industrial capacity. It is obvious, further, that we have developed a more human standpoint in the consideration of industrial organization and are not ashamed of some sentiment in connection with our business requirements.

We are not yet at the point where we realize that production efficiency is almost a by-product of organization harmony, but we have begun to realize that a man's health, his home conditions, his financial status, his recreation and his surroundings all exercise an influence upon his productive capacity which is none the less important because it is not capable of exact measurement.

There has been a big development in the last fifteen years in the direction of providing light, airy, comfortable and pleasant places to work, in extending the facilities of the industrial establishment for the purpose of the workers' recreation, in establishing hospital facilities and other arrangements calculated to maintain the health of the worker and in providing such surroundings as will tend to suggest pleasant, comfortable and healthful associations and not merely the grinding necessities of labor, which were frequently suggested by the older factories in their deficient conditions and depressing environment.

Surroundings That Stabilize Labor

Managers and employers of labor all over the country are giving attention and consideration to all possible factors which may have a bearing upon either the stability of labor in its productive work, or its efficiency in quantity of production. A trip into this or that factory is always suggestive to the man whose eyes are open, because of the different methods employed by the different concerns in dealing with these human necessities and in endeavoring to provide such working surroundings as will stabilize the conditions.

It is indicative, as a natural development out of the work of the previous years and the present conditions in the building trades, that so many manufacturers should be interested in the housing question at this time and actively engaged in finding a solution, or providing a solution, for the housing trouble in their immediate localities.

Much discussion has occurred upon the best ways of tackling all these matters, the best methods to be adopted in taking care of the necessities of the case and upon the developments which can be worked out without the stigma of paternalism on the one hand or without radical departures from practice, on the other hand, which may not be justified.

About two weeks ago the writer visited a large concern in New England, one of the old established New England manufacturers engaged in the metal trades, noted for fair treatment of the worker and for the justice of their dealings with the workers' demands or necessities. This concern established, some little time ago, a system of representation by elected representatives of the employees upon a joint committee with an equal number of representatives of the management; to have jurisdiction over the question of wages, hours and working conditions which demand consideration from time to time and to evolve a method of dealing with the personal grievances of the individual employee in such a way that they would be properly adjudicated.

System Considered Satisfactory

This system is based upon a similar plan to those adopted by the Standard Oil Co. of New York, The Midvale Steel Co., Colorado Fuel & Iron Co. and others that have been mentioned in AUTOMOTIVE INDUSTRIES. It has been in operation for about a year, and conversation with the executives of the company and with the workers developed that it is considered entirely satisfactory on both sides. The employment manager in this particular institution, or, rather the manager of industrial relations, has proved to be an unusually capable man, having fully satisfied the owners of the concern, and at the same time sufficiently satisfied the workers that his position and the justice of his actions have been commended by the labor leaders in that vicinity.

In the course of the working out of this system, or during the year, it developed that a number of the workers were carrying large amounts of cash, representing their savings, because of the inability to open bank accounts during the hours when they were off duty and their diffidence about going to the banks to deposit money or draw it out during the hours of work while wearing working clothes. This suggested to the management the possibility of making an arrangement with the local banks by which the employees could open savings accounts at the pay office of the company, receiving receipts for these accounts and having them credited on the books of the savings banks as though they were deposited at the receiving teller's window in the ordinary way. The system by which this was arranged was copy-

righted by the man who got it up and bought from him for use by this concern.

In many of its details it is somewhat similar to the thrift stamp book, except that each bank has its own books and stamps and methods of receipting, which have no value outside of its own doors. The details of the system, of course, are important in its actual operations, though the problem is sufficiently simple that any intelligent accountant can arrange for a proper system of taking care of the actual transactions.

The interesting point about this whole thing was that in this manufactory, which is some distance from the business section of town, there were thousands upon thousands of dollars lying idle in the pockets of the workmen, not because they did not see the value of a bank account or because they were unwilling to trust the bank, but because it was inconvenient to get to the bank during the hours when it is open; while during the leisure time of the worker when he was prepared to go into the center of town all the banks were closed and there was no possibility of depositing or withdrawing any money.

Has Met With Enthusiastic Support

It further developed that there was a great deal of enthusiasm among a large proportion of the workers for the opportunity presented by this arrangement and a great many of them took immediate advantage of it to deposit considerable sums, representing savings which they had been obliged to carry around for lack of any other means of care.

This is not the only case in which arrangements have been made to stimulate the saving of money by the workers and to make it easy and convenient for them to deposit those savings in a recognized institution for the purpose.

A departure from this scheme, with the same object in view, was indicated in the annual report of the Lever Bros., Ltd., makers of Sunlight soap, in Liverpool, England. It was stated in this report that the company had decided to do away with the method of paying the workers at the office, necessitating their standing in long lines waiting to be paid, and instead it had arranged with the banks in Liverpool to open an account for every individual employed with the company and had arranged to deposit at the bank each week an amount equal to the amount earned by the employee, which amount could be withdrawn from the bank or used as an account at the bank in the usual way. It was calculated that with the number of employees at the works it was necessary for some of them to wait half an hour in order to be paid, and that this was not only inconvenient for the workers but distasteful to them as well, besides making it troublesome for them to go to the bank afterward and deposit any money. It is understood that the banks arrange to be open special hours to accommodate the employees of this company who may desire to deposit or withdraw money and who cannot arrange to be at the bank during the ordinary hours of operation.

Wherever it has been made convenient for the workers to deposit money in the regular financial institutions and to save money, there has been a large response from a very considerable body. Although the examples of industrial corporations offering these opportunities to their workers are not very numerous, they suggest that the reason why so many of the workers have not used the banks as depositors is not so much because of their dislike for the banks or their desire to spend what they earn, but that the inconvenience of reaching a bank to deposit the money which represents their surplus may have a great deal to do with their neglect in this matter. The advantage, of course, of workers saving money is so obvious that it is not necessary to dwell upon it. The advantage of encouraging them to deposit their savings in the regular banks so that the money may be kept in circulation is equally obvious; but there is an additional advantage to the concern which provides opportunities of this kind for its workers, that they are directly contributing to the stability of the individual worker and to the stability of the workers as a part of their organization and providing a service, the value of which a considerable proportion of the workers appreciate and take advantage of.

The plan, of course, calls for a slight additional expense on the part of the company, and this must be justified by the importance of the matter. The executives of the companies who have adopted the idea in one form or another evidence their information of its value and their impression of its importance from the spirit in which it has been received by the workers and the advantage that has been taken of it wherever any such plan has been put in motion.

It is mentioned because all items of that kind have a bearing upon the labor situation and the interest of the worker in the banks of his locality. The interest of the worker in saving is an important element in stabilizing the organization and in introducing a more conservative viewpoint among the workers themselves. They are apt to judge matters more carefully when they own a little property and have a real interest in the locality and the country.

Property Ownership Creates Sense of Responsibility

Comfortable housing conditions and the ownership of property, either in the form of a house or in the form of bank savings, bonds or some other tangible property, are very important incentives to the development of responsibility and a sense of orderly necessity in politics and in business. It is not a mere coincidence that most of the irresponsible radicals of all types are born and brought up in the cities or among the classes who have no interest from a financial standpoint in their local community, in their national government. To such people any change is a good change. Having no responsibility either from the standpoint of ownership or the direct payment of taxes, but possessing political power to the extent of the vote, they cannot lose much as far as they see by any radical development, no matter how theoretical it may be, and they may gain a great deal.

The stability of the French nation is largely due to the individual financial interest in the Government and the locality, and the employer who encourages, even to the extent of considerable expense, the habit of saving and the development of property ownership, by extending the convenience so that it will be easy for the workers to arrange such savings, is providing an opportunity for the development of stability in its organization and its locality which will more than compensate for any expense which may be involved.

BRITISH aircraft papers publish particulars of the Tarrant Giant triplane, said to be the largest heavier-than-air machine ever built. It has six Napier Lion engines, four of which are mounted on the bottom plane and the other two between the middle and top plane. The fuselage is of the monocoque type and of very good streamline form. Originally the machine was designed for long distance bombing, but after the armistice was signed it was decided to convert her into a passenger carrying plane. The span of the middle plane is 130 ft. and the height from the ground to the top plane 37 ft. 3 in. The weight of the machine is approximately 45,000 lb., of which 9000 lb. is available for passengers and cargo and 10,000 lb. is taken up by the fuel.

HORSELESS AGE SUBSCRIBERS
Subscriptions for the Horseless Age transferred to the subscription list of AUTOMOTIVE INDUSTRIES in the merging of the two publications will be completed in full by the weekly issues of AUTOMOTIVE INDUSTRIES to the dates of expiration shown on the records of the Horseless Age Co.

Owned by United Publishers Corporation, Address 239 West 39th St., New York; H. M. Swetland, President; Charles G. Phillips, Vice-President; W. H. Taylor, Treasurer; A. C. Pearson, Secretary.

Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.

Member of the Audit Bureau of Circulations.

Automotive Industries—The Automobile is a consolidation of The Automobi'e (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Less Publicity, More Action

IF official Washington would actually put into effect but a small percentage of the numerous excellent plans for co-operating with industry that have been announced in the past six months, the American government would be the most helpful of all governments to the industries of the nation.

The desire for publicity has become the "wrench in the gears" of government operation. Department heads apparently call meetings of their subordinates, ask for suggestions, list them and then call for the publicity director, who turns out many pages telling what the department plans to do for the benefit of American industry.

Newspapers and other publications carry the stories. The bureau clips the notices and files them for evidence to be presented to the Congressional committees, and then, as the main object—publicity—has been secured, the enthusiasm wanes and the schemes die. Later a new set of ideas is compiled and the same plan followed. When the bureaus and departments think more of aiding industry—of direct profitable action—and less of publicity, the only value of which is to obtain the appropriations necessary to insure jobs, there will be a more genuine governmental co-operation with business.

What Shall We Do With Our Bureau of Standards?

DURING the past two years the Bureau of Standards at Washington was engaged almost entirely in scientific work connected with the prosecution of the war. Feverish activity was developed by practically every department; new buildings were erected, much new equipment was installed, and the personnel was greatly increased. Under the imperative demands of the war the Bureau grew as much in two years as it probably would have grown in two decades under normal conditions.

The cessation of hostilities, and of practically all manufacturing activities in connection with the war, has caused a slackening in the demands made upon the Bureau. As an instance in point, the immense amount of work which was done in connection with the development of the Liberty engine and its accessories has been carried to fruition, and there is less demand than during the war for the use of the special facilities collected for this work. The activities of practically all branches of the Government are shrinking at a very rapid rate, and the calls made by Government departments have greatly lessened.

We are thus left with a highly developed national institution for scientific research, without any definite program for its utilization for the best interests of the Nation. True enough, the Bureau was originally organized for a definite purpose, and previous to the war it had a well-defined program, but anyone who watched its expansion during the war knows that it has long outgrown this program.

During the past few years, industrial research has become a subject of tremendous importance. It was well-organized research that gave Germany its lead in certain industrial lines previous to the war. Thus, when hostilities broke out the allied countries were cut off from their sources of dyes, optical glass, and certain medicines, among other products. Their only salvation lay in rapidly organizing for intensive research work, and this the respective countries did at once. According to all accounts, the work undertaken along these lines proved highly efficacious. The men engaged in it thus proved themselves capable research workers, and incidentally the value of scientific research was strongly brought home to many people who formerly were inclined to scoff at it. In England, particularly, there has been much talk of co-operative industrial research, and a committee has been appointed under Government auspices to look into plans.

It is generally felt that in the coming struggle for the world's markets for manufactured products,

scientific research will play a very important rôle. At the present time very effective research work is being done by a few of our large corporations, such as the E. du Pont de Nemours Corp., General Electric Co., Eastman Kodak Co., and others, but the great majority of our manufacturers cannot afford their own research laboratories, and if these are to be benefited by the possibilities of research work it must be carried on co-operatively or through the instrumentality of the Government.

As already stated, the Bureau of Standards has far outgrown its original purpose. It is no longer an institution merely for calibrating thermometers and checking weights and measures, but it is a vast research laboratory well organized, well equipped and well staffed. It is quite apparent that the Bureau could be of great service to the Nation's industries, and particularly to the automotive industries, if it were placed on a somewhat different basis. At the present time it concerns itself only with the scientific problems which arise in the work of the various Government departments. Of course, during the war these problems covered nearly the whole range of industrial activities, but in peace times the situation is entirely different.

The Bureau of Standards could act both as a research and a testing laboratory for the industries. As a testing laboratory, it would be an authority in which the public would have confidence. It may not be amiss to mention a specific example of the class of testing work in which the Bureau could engage. Since the sharp increase in the price of gasoline some years ago, a large number of so-called fuel savers have been placed on the market, for some of which rather extravagant claims have been made. It is impracticable for the manufacturers or dealers to give a convincing demonstration of these devices to each customer, as to do so would often involve expense greater than the cost of the instrument. If the inventor or manufacturer of such a device could have it tested by the Bureau, and get a certificate of performance, it would be a tremendous help to him if the performance was creditable. In this way the Bureau would help to gain recognition for inventions of merit, while at the same time its activity would tend to keep off the market devices without practical value, as the public probably would soon become educated to asking for an official performance certificate.

The Bureau and the Automotive Industry

To the automotive industry the Bureau could be of immense service in connection with fuel problems. It is true that problems connected with the production of petroleum fuels are being dealt with by the Bureau of Mines, but this department does not concern itself with the utilization of the fuels in engines. Other automotive problems that can only be solved by scientific research on a large scale relate to lubrication, ignition, and to the properties of metals and other materials of construction.

We would urge upon the automotive industry and the various organizations representing it, such as the National Automobile Chamber of Commerce, the Motor and Accessory Manufacturers, the National Boat and Engine Manufacturers' Association, and the National Implement and Vehicle Association, to ponder this question thoroughly. If they believe that the Bureau of Standards can be of material service to them it behooves them to speak out and ask that it be made available for that purpose. The fate of the Bureau rests with Congress. But we cannot expect our Senators and Representatives to try to find work for the Bureau. If no demands are made for its services from the industries, then it is likely that appropriations will be withheld and that some parts of the institution will be closed. We all know that there is a strong demand for retrenchment, and the tendency for Congress would be to cut expenses where it could be done with the least opposition.

Now, economy is generally regarded as a virtue, and correctly, but there is such a thing as false economy, and it would certainly seem false economy to condemn to idleness an institution in which the Nation has invested millions of money, which during the war demonstrated its ability to "produce results," and which could be of great assistance to our industries in improving their products.

More Intimate Contact Needed

What is needed is more intimate contact between the Bureau and the industries. The Bureau should be organized on such a basis that its services would be available to any firm requiring research or test work done for such equipment as the Bureau possesses is necessary. Of course, the tests or other work should not be made entirely gratis, as in that case the staff might be overwhelmed with requests for investigations of matters of little importance. Some of the expense might well be borne by the Government, however, as any results achieved would be of commercial advantage to the Nation, and it is a legitimate function of the National Government to aid the Nation's commercial interests. In any case, any fees paid for tests should go directly into the National Treasury and not to the Bureau, the latter being supported entirely by Government appropriations, so that any causes that might tend toward commercialism would be eliminated.

If the automotive industry feels that it can profit from continued research work of the Bureau, somewhat along the lines on which the latter has been working the past two years, then it should not fail to make its voice heard immediately, for once a decision has been made it is always difficult to get a question reopened for discussion. Let the National Automobile Chamber of Commerce, the Motor and Accessory Manufacturers, the National Boat and Engine Manufacturers' Association, the National Implement and Vehicle Association, the American Gear Manufacturers' Association, the American Drop Forge Association, the Electrical Equipment Manufacturers' Association and other industrial organizations petition Congress. Let every individual manufacturer write to his Congressman, that the necessary appropriation should be made to keep the Bureau of Standards going at full capacity, for the benefit of American industries.

Latest News of the

Average Speed of 92.46 M.P.H. Made by NC-4 in Flight to Lisbon

Last Leg of Trip Made Without Incident, Under Favorable Conditions—Hawker Made 1289 Miles Before He Was Forced to Alight

NEW YORK, May 28—The flight of the NC-4 yesterday from Ponta Delgada to Lisbon, 921.21 land miles, in 9.44 hr., completes the initial flight from American to European shores. The NC-4, an American naval plane, was commanded by Lieut. Commander A. C. Read. The following data of the flight, reduced to land miles, were compiled at Washington:

Course	Date May	Distance Miles	Time Hrs.	Speed M.P.H.
Rockaway-Chatham (forced landing about 100 miles off Chatham)	8	345.45	5.45	59.87
Chatham-Halifax	14	368.42	3.51	97.87
Halifax-Trepassey	15	529.69	6.20	83.60
Trepassey-Horta	16-17	1,381.81	15.18	90.27
Horta-Ponta Delgada	20	172.72	1.45	99.83
Ponta Delgada-Lisbon	27	921.21	9.44	94.50
Complete Ocean Flight Trepassey-Lisbon		2,475.75	26.47	92.46

The average speed of the planes is an interesting part of the table. The wind velocity is a factor in the variation. The NC boats in tests before this flight developed an average speed of 65 m.p.h. in still air.

The NC-1 and the NC-3, which started with the NC-4 from Rockaway Air Station, made the flight to Trepassey successfully, but failed to reach Horta because of fog. The NC-1 was within 250 miles of Horta when forced to descend to get its bearings and was unable to again take the air. The plane became waterlogged and the crew had despaired of rescue when picked up by the steamer Ionia. The steamer took the plane in tow but the line broke and the craft was lost. The NC-3, commanded by Commander Towers, lost its bearings in the fog and was forced to alight 80 miles south of the course. The flight was equal to the distance to Ponta Delgada. Only a 2-hour supply of fuel remained and no effort was made to take the air. Instead the NC-3 taxied to Ponta Delgada, 205 miles, entering the harbor under its own power. These flights were not in competition for the London Daily Mail prize.

Hawker Rescue

The dramatic rescue of Harry G. Hawker, pilot, and Commander McKenzie Grieve, navigator, of the Sopwith biplane, as announced last Sunday, was a feature of the week's air news. This plane started from St. John's, Newfoundland, at 1:51 (New York time) Sunday, May 19, competing for the London Daily Mail prize of $50,000 for a continuous transatlantic flight.

The plane and crew were not heard from after the start until the Danish steamer Mary signalled on Sunday that the men were aboard. The steamer had no wireless and had been unable to announce the rescue of the aviators. Hawker and Grieve were taken off the Mary by a British destroyer and given a tumultuous welcome in Scotland and England on their trip from Scapa Flow to London.

Hawker, in his own account of the flight, says that for the first 5½ hours of the journey all went well at a height of 15,000 ft. Owing to choking of the filter, the plane was lowered, but after 12 hours of flight the circulation system again choked. It was found that the trouble was caused by solder and other refuse and it was realized that the trip could not be continued. Then the plane turned across the steamer lane and after two hours sighted the steamer Mary and dropped to the water in front of it. Owing to the rough sea, the men were taken off with difficulty and the airplane and contents were abandoned, but later picked up intact by the American ship Lake Charlottesville and will be taken to Falmouth.

An official announcement by the British Admiralty was:

THE HANDLEY-PAGE TRANSATLANTIC FLIER

Handley-Page "Berlin Bomber," which will attempt a transatlantic flight from Newfoundland. It is fitted with Rolls-Royce engines and with both tractor and pusher propellers, the latter having four blades. It was a machine of this type which last winter made the flight from England to India, a distance of approximately 5800 miles, including 700 miles across the Mediterranean.

Automotive Industries

"Hawker and Grieve were picked up in làtitude 50.20, longitude 29.30, having alighted close to the little Danish steamer Mary, owing to stoppage of circulation in the water pipes between the radiator and the water pump."

This statement would indicate that the aviators landed in the Atlantic 813 land miles from the coast of Ireland and approximately 1289 land miles from the point of their departure from Newfoundland.

Hawker, in his statement, says that he and Grieve were picked up 14½ hours after the start from St. John's.

—

A French Flight

It was announced from Paris that Lieut. Roget left that city at 6 a. m. May 24, and flew 1367 miles to Kenita, 18.6 miles from Rabat, at an average speed of 118.8 miles per hour. He has started on a transatlantic flight to Brazil by the way of Rabat. His descent was caused by engine trouble and the machine was damaged in landing on rough ground. It is expected that the flight will have to be abandoned.

—

Wills and Lee to Put Up Plant for New 6-Cylinder Car

DETROIT, May 28—C. L. Wills and John R. Lee, both recentiy connected with the Ford Motor Co., to-day announced that they have taken an option on 2000 acres on the St. Clair River between St. Clair and Port Huron, 50 miles north of Detroit, on which they will build an automobile factory to employ, eventually, 35,000 men.

The factory will build a 6-cylinder car which Mr. Wills has designed. The price of the car has not been announced.

The site has a 3-mile frontage on the St. Clair River and a plant will be designed for the entire production. Arrangements are being made to bring iron ore from the mines by boat.

Included in this site is a village which will be the foundation of a model city to be constructed by this company.

Mr. Wills was chief engineer of the Ford company and had been associated with Henry Ford for two years before the present company was organized. He had been with the Ford organization for 18 years.

Mr. Lee was in charge of the social welfare, profit sharing and bonus departments of the Ford Motor Co.

These men are regarded as having ample capital, but reports have it that other men are associated with them, but no names are mentioned.

Belgian Manufacturers Preparing to Get Back Into Production

Plants in Deplorable Condition—Ready Cash Scarce—Minerva Motors Reveals Definite Plans of Production and Gives Picture of Recovered Factory

ANTWERP, May 1.—(Special Correspondence.)—The automobile manufacturers of Belgium, who recovered their factories shortly after the signing of the armistice, are at a loss to predict when they will be able to resume production. The plants were in a deplorable condition, and most of the manufacturers have been so busy cleaning up and restoring their plants that they have been unable to give the proper attention to future work. Another drawback is that most factories have an abundance of requisition bonds and no money, and it is difficult in the present market to buy without ready cash.

An exception to this is the Minerva Motors Societe Anonyme. S. de Jong, director of the Minerva works, has definite plans for production, and says that he expects his company to be the first in the market. Mr. de Jong began his preparations for production while in exile in Holland and now will benefit by the plans and the work done there during the war. To a representative of AUTOMOTIVE INDUSTRIES, Mr. de Jong said:

"The first impression when I walked through our plant was that a few thousand Bolsheviks had been let loose in our place for a certain length of time, after which an earthquake had knocked everything to pieces. Not one thing was in its accustomed place, where we left it in 1914. Things which used to be on the ground floor at one time we found in the opposite direction on the roof on the sixth floor.

"We missed 750 machine tools which the Germans had carried somewhere in Germany, with the necessary electric motors, shaftings, pulleys, belting and lots of other installation material. Our warehouses have been robbed of a great part of their contents, and especially of practically every part of brass, aluminum, antimony and other valuable goods. The last six months the Germans had requisitioned us to deliver them every week 1,000 kgs. of brass or bronze goods, and, of course, our stock of spares in that metal has practically disappeared.

"On the other hand, as they had been repairing cars in our place for the last four years, we found several hundreds of broken up lorries of German make, and a few hundred broken up passenger cars from the same source. They were of the most heterogeneous types and ages, and probably included all cars found unrepairable during the war.

"More than 200 beds were distributed in practically all parts of the building, as parts of it had been used for sleeping quarters.

"The first few months we have been employing 400 to 500 men in cleaning the premises. We have been whitewashing, cleaning, painting as much as we could. Everything which did not belong to us has been removed and we have put in order as much as possible what remained that belonged to us and tried to take an invenotry of what was missing.

"We are having some trouble with labor, but fortunately until now these troubles are not so great that we cannot overcome them. Practically all our workmen, a great many of whom had been spread all over England, France, Holland and other countries, have come back and are happy to work in the old place again.

"Fortunately, we had been working during our stay in Holland to prepare substitutes for what we knew had been taken away from our factory. Several hundreds of special machines had been ordered in your country, many others in England and in Holland. During the war we have been making, with the help of a few hundred interned Belgian soldiers, 150 machine tools which we have since brought here.

"As soon as we returned we started buying material and as we have prepared to a great extent the jigs and tools for the new types of cars we will bring out soon, we are now simply awaiting the steamers which will bring over in time the machines and material from your country, as well as from England and France, to be able to start deliveries of our new cars within four to five months.

"In the meantime, we have about 300 men busy repairing the cars for the Belgian army, which army, as you know, has still in use a great proportion of Minerva cars. These were requisitioned in August, 1914, from the private owners and have all been through the war. Some of these cars requisitioned in 1914 were of respectable age then."

France Will Drop 45 Per Cent Import Duty to 15 Per Cent in 1920

Import Restrictions and Heavy Duty on American Cars During War Led Manufacturers to Protest to C. C. Hanch—Demand for American Cars Interrupted by War

Special cable to AUTOMOTIVE INDUSTRIES

PARIS, May 26—It is announced that after the signing of the Peace Treaty, France will adopt a 45 per cent duty on American automobiles until January, 1920. After that date, the duty will be made 15 per cent.

—

This announcement by cable from W. F. Bradley, European correspondent of AUTOMOTIVE INDUSTRIES, follows recommendations of similar import that were made by the International Congress of Automobile Manufacturers, which met in Paris early in March. The Congress, which included automobile manufacturers of all European countries except the German allies, recommended a tax of 10 per cent on European automobiles and a 45 per cent tax on American.

At that time the import tax in France was 70 per cent on vehicles weighing less than 2700 kilos, but the importation was allowed only by license. About that time the Groupement des Importateurs d'Automobiles Americaines sent a protest to C. C. Hanch, then in Europe as representative of the N. A. C. C. This protest asked Mr. Hanch to take up at once the problem of opening French trade to American cars. The importers in this protest said:

"Before the war the customs duty on American automobiles was frs. 750 ($150) per 100 kgs. Now, on June 24, 1916, the tariff was increased to 70 per cent ad valorem on the value of the goods, augmented by all charges for the transportation, war and maritime insurance; this in order to protect French industry, as all the factories were occupied on war work. At this rate, a car costing, say, frs. 8500 ($1700) in America would pay about frs. 10,000 ($2000) duty. On April 1, 1917, the French government passed a law prohibiting, purely and simply, all importations of cars of foreign manufacture."

They also pointed out that during the period of hostilities they made no plea for their trade but had waited patiently until conditions had changed. At the time of writing the protest they asserted that the French manufacturers were advertising new models as ready for sale to the public. Hence, the further restrictions of importations could not be with a view of protecting the French manufacturers. They expressed the belief that importation of American cars would be beneficial to the entire country. They did not ask a return to pre-war custom tariffs but asked a tariff that would permit them to resume business.

Figures on American passenger cars exported to France follow:

Fiscal years ending June 30

Year	Number	Value
1912	574	$469,721
1913	818	615,086
*1914	1,427	919,060
1915	451	252,909
1916	2,087	1,428,825
1917	1,367	836,557
1918	1,169	1,518,858

*Government year 1914 includes 1914 to June 30—two months before declaration of war.

Calendar year 1918 (to Dec. 31)	1,003	1,134,818
(Obviously this overlaps fiscal year 1918)		
1919		
Jan.	28	128,619
Feb.	82	281,131
Mar.	73	170,893

These figures indicate that there was, before the war, a growing demand in France for American cars. The interruption of the growth of this business in 1915 was due to war conditions. The figures during the war have no direct bearing on the trade situation.

—

Champion to Make 35,000,000 Spark Plugs

TOLEDO, May 26—The Champion Spark Plug Co. proposes to make 35,000,000 plugs this year. Last year 25,000,000 were produced as against 24,000,000 in 1917. Increased production is made possible by the enlargement of the plant through the purchase of the old Bissell Mfg. Co. buildings. The company now employs 850 in Toledo and 750 in its insulator plant in Detroit.

—

Nitro Carbureter Sales Through C. A. S. Engineering

NEWBURGH, N. Y., May 26—The Sunderman Carbureter Corp. has closed a deal with the C. A. S. Engineering Co., Detroit, whereby the latter company will handle the sales of the Nitro carbureter to the manufacturing trade.

Hollier Back in Production

CHELSEA, MICH., May 26—The Lewis Spring & Axle Co. is now getting into fair production on the Hollier six. Manufacture of this car, which was discontinued during the war, has now been permanently resumed, but no production schedule has been prepared for the coming year. About 400 men are on the payroll and this number will be increased as production expands.

—

Standard-Detroit Tractor Dissolving

DETROIT, May 26—The Standard-Detroit Tractor Co. has filed a petition for dissolution in the circuit court. The petition was signed by M. L. Pulcher, head of the Federal Motor Truck Co., and Edward P. Hammond, both stock holders in the company, and others. Assets amount to $1,811, and liabilities $59,490. The company was incorporated some time ago for $100,000 for the purpose of manufacturing a tractor attachment to Ford cars.

—

Annual Convention of Drop Forge Assns.

PITTSBURGH, May 26—The annual convention of the American Drop Forge Association and of the Drop Forge Supply Association will be held June 12 to 14, at the William Penn Hotel. Some of the subjects to be discussed are: "The Bonus System in the Entire Forge Shop;" "Testing Materials;" "Electric Welding as Applied to the Forging Industry;" "Sand Blasting versus Pickling;" "Heat Treating Problems That Originate in the Forge Shop;" "Powdered Coal Developments in the Forging Fields."

Officers of both organizations will probably be continued in office. Officers of the American Drop Forge Association are: President, E. J. Frost, of the Frost Gear & Forge Co., Jackson, Mich.; vice-president, J. F. Connelly, of the Champion Machine & Forging Co., Cleveland; secretary, A. W. Peterson, of the American Drop Forger, Pittsburgh; treasurer, E. B. Horne, of the Packard Motor Car Co., Detroit.

Officers of the Drop Forge Supply Association are: President, H. N. Taylor, of N. & G. Taylor Co., Philadelphia; vice-president, Charles Harmon, Jr., of the National Machinery Co., Tiffin, Ohio; secretary-treasurer, A. L. Wurster, of the Sizer Forge Co., Philadelphia.

Passengers Landed on Hotel Roof

WASHINGTON, May 24—An army dirigible type A-4 made a successful landing of passengers on the roof of the Hotel Statler, Cleveland, to-day, following a flight from Akron. The dirigible discharged two passengers and took two others aboard for the return trip. The transfer was made on a landing stage built especially on the roof of the hotel.

—

Record Washington-New York Flight in 84 Minutes

WASHINGTON, May 26—An airplane piloted by Col. Gerald C. Brant and Lieut. Howard Birkett flew 220 miles, from Washington to New York, Saturday in 84 minutes, an average of 157.2 m.p.h., breaking all speed records between these points. The aviators had the advantage of a 60-mile gale behind them. They maintained an altitude of 8000 ft. This trip ended a flight from Houston, Tex., by way of Dayton, Ohio, and Washington. The entire distance of 1725 miles was covered in 994 minutes of actual flying time.

—

National Gas Engine Assn. to Discuss Bigger Business

CHICAGO, May 26—Bigger business is the general theme of the annual convention of the National Gas Engine Association to be held here at the Sherman hotel, June 2-3. Informal group meetings will consider stationary and oil en-

gines, farm engines, tractor engines, farm lighting plants and accessories. The two-day meeting will be closed by a Victory dinner Tuesday night at which the guest of honor will be W. B. Wilson, Secretary of Labor. He will speak on relations of capital and labor before and after the war. James H. Carter of the National City Bank of New York is the other speaker for the dinner.

—

150 Manufacturers to Be Represented at Denver

DENVER, May 27—About 100 tractors and 750 farm implements, representing a total of nearly 150 manufacturers, will take part in the Mountain States National Tractor Demonstration, to be held June 9-12 under the auspices of the Denver Tractor Club, Denver Civic and Commercial Association and the civic body's Agricultural and Livestock Bureau. On the 2300-acre demonstration ground, 100 tents will be put up for the exhibiting firms.

—

Investigation of Rubber Substitute Wanted

WASHINGTON, May 26—Investigation and study of methods for using sage brush and greasewood to produce rubber, alcohol and acetic acid was asked in a bill introduced in Congress by Representative Raker. The bill provides for the appropriation of $5,000 for making the investigations and tests.

—

Extend Time of Tax Payments

WASHINGTON, May 26—An extension of time has been allowed to automobile and parts manufacturers and operators of motor truck, freight or express routes for filing return of taxes due under the Revenue Act for the periods from February 25 to March 31, and from April 1 to April 30, 1919, until June 15, 1919. The extension has been granted because of an unavoidable delay in the printing and distribution of the necessary blank forms for making the returns.

The specific sections of the Act referred to are No. 900, which is on the manufacturer's selling price of trucks, passenger cars, motorcycles, accessories and parts, and No. 500, which imposes the tax on transportation of goods by freight or express on motor trucks competing with rail or water.

Delay has also been granted for the filing of returns on admissions to automobile shows for the same reason, until June 15.

—

Splitdorf Training Foremen

NEWARK, N. J., May 24—The Splitdorf Electrical Co. has organized a group of foremen of its various departments to study modern production methods. The course will last three months and will include training in handling men, a complete study of materials from purchase to final product, a study of the plant, organization, costs, industrial relations, safety and co-operation.

Labor Shortage In Detroit Reduced

Automotive Concerns and Other Agencies Brought Many Here—Fear of Losing Foreign Labor

DETROIT, May 24—The last week has seen a great improvement in labor conditions in Detroit. The shortage, which a month ago was estimated at 50,000 workers, has been decreased to 20,000 by the efforts of all automotive concerns, the United States employment office and other employment agencies, which have brought thousands of men to Detroit. Many of the factories are advertising outside the city for men, while others have field representatives busy in many sections. Hundreds of mechanics and other skilled workers have come in from Buffalo and New York City within the last few days.

Grand Rapids Short 2000 Men

Grand Rapids, a furniture center, is short 2000 men, while Pontiac, Battle Creek, Flint, Jackson, Lansing, Traverse City, Port Huron, Saginaw, and Bay City have all sent in urgent requests for workers at once. The shortage seems to be general in all of the manufacturing cities of the State.

Hundreds of men, both skilled and unskilled, are being brought from the copper countries. Work in the copper fields is slack at this time, many of the mines operating only on a 50 per cent schedule, resulting in a labor surplus there. So many automobile labor representatives from Detroit, Flint, Lansing and other lower Michigan points are working in upper Michigan, employing workers for the industrial centers, that the newspapers of that section are voicing a protest. The press is urging the workers not to be stampeded because there is a little lull in the copper industry, following a very high pressure in production because of war needs. They declare that with the signing of peace terms a great boom is due to hit that section.

Workers Brought from Other Cities

Factories bringing the men in from outside find this method very costly and sometimes without fair results. One plant recently brought 300 workers to Detroit from Chicago and nearby points. The men were told to report for work at a certain time, but out of the 300 only 75 appeared. There are many instances of this sort. Pontiac recently imported 400 workers, 320 of whom left town within a week. The great reason for a laboring man leaving is the living condition. He finds homes unobtainable, rents excessive and food prices extravagant. If Detroit and neighboring industrial towns hope to solve the present shortage by bringing in men from the outside, they must first solve the housing and living problems.

Common labor in Detroit is being paid from 50 cents to 60 cents an hour, while skilled labor runs from 65 cents up to $1.25. Tool makers and other highly skilled mechanics are working on scales ranging from 80 to 90 cents an hour. The minimum day wage for common labor is approximately $5, and in some cases more. The skilled employee is averaging between $35 and $50 weekly.

One problem causing the employer of labor more or less concern is the exodus of foreign workers and a threatened permanent shortage of common labor. In the last 4 months 2700 Detroit aliens have left for their native lands. Between 600 and 700 are applying monthly at an emigration office for passports. If this exodus of aliens continues, and there is every indication that the movement is spreading, Detroit alone is going to lose between 10,000 and 12,000 workers within the next few months. Emigration restrictions are rather rigid at present, owing to the continued enforcement of war rulings, but with the declaration of peace there will be a relaxation of many emigration laws, and hundreds of men barred because of technicalities at present will then be permitted to leave.

Few Germans Apply for Passports

The greatest percentage of those desiring to return are Italians, Belgians, Russians, Serbians, Austrians, and French. The Austrian, while clamoring for passports, is held up, except in rare cases, because he is still an alien enemy. Few Germans have applied for passports because they know they will be refused.

Employers here are closely watching legislative developments at Washington regarding immigration. It is feared that Congress may decide to bar newcomers, which manufacturers regard as serious, taken in connection with the tendency on the part of many European countries to keep workers at home.

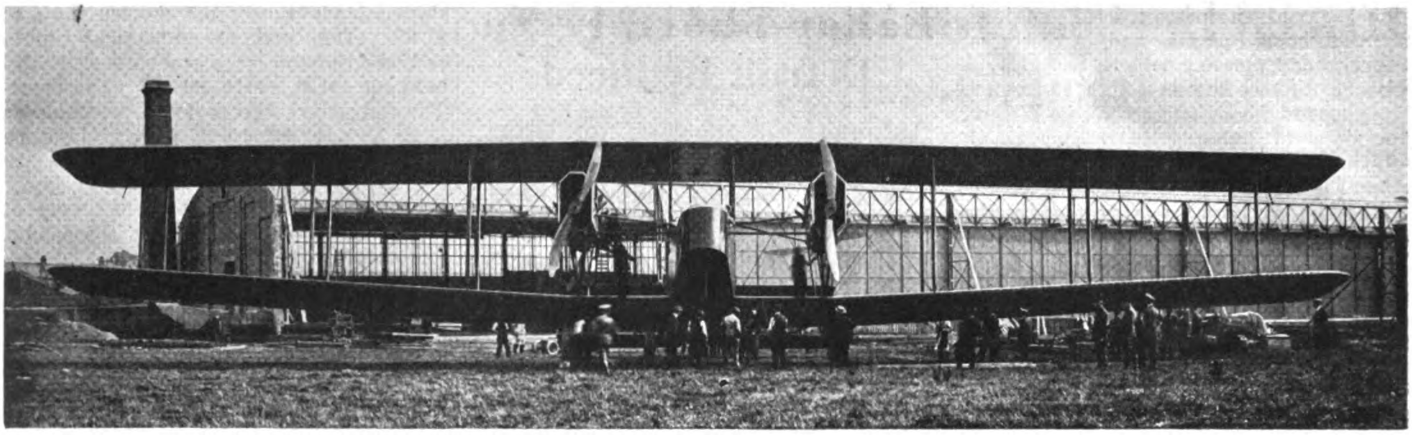
—

Employment Conditions Improve

WASHINGTON, May 23—Reports received from the U. S. Employment Service for the week ended May 17 show an improvement in unemployment conditions. Reports from 87 cities show 39 reporting a surplus as compared with 42 cities reporting a surplus the week previous. Fifteen cities report a labor shortage.

New York reported 126,000 surplus, Cleveland 30,000 and Pittsburgh, 20,000. The Middle Atlantic and New England states report labor surpluses. Cleveland, Youngstown, Cincinnati, and Dayton report unemployment, and Akron reports a shortage.

There is a shortage of labor throughout the South, chiefly in the agricultural district. Los Angeles reports 5600 unemployed, San Francisco, 2000 and Oakland a shortage of 350. Conditions in the Northwest are good, with a shortage of labor reported from all cities. The aggregate surplus of labor shortage of the country of 310,000 is not a serious total and is considered close to the normal.



The Handley-Page airplane, now at Newfoundland in preparation for a transatlantic flight

Rubber Exports for February from Brazil and Peru

WASHINGTON, May 28—The total exports of crude rubber from Para and Manaos, Brazil, and Iquitos, Peru, during the month of February, 1919, amounted to 9,242,309 lb. compared with 6,587,710 lb. for the same month in 1918. Shipments to the United States aggregated 4,434,206 lb. and to Europe 4,808,-103 lb. compared with 3,453,272 lb. and 3,134,438 lb., respectively, last year.

The several grades of rubber are shown in the following table:

	From Para		From Manaos		From Iquitos	
	To United States lbs.	To Europe lbs.	To United States lbs.	To Europe lbs.	To United States lbs.	To Europe lbs.
Fine	634,075	1,863,401	1,274,344	1,570,468	.....	317,444
Medium	111,422	38,147	585,247	122,965	.....	4,256
Coarse	334,319	98,152	821,488	152,251	.....	14,521
Caucho	189,533	348,617	439,686	242,817	44,092	34,064
Total	1,269,349	2,348,317	3,120,765	2,089,501	44,092	370,285

Foreign Trade Opportunities

WASHINGTON, May 27—The Bureau of Foreign and Domestic Commerce has received requests for cars and parts, airplanes and parts, tractors, motorcycles, and accessories agencies of business from individuals and companies in foreign countries. For further information address the Bureau of Foreign and Domestic Commerce, Department of Commerce, and specify the Foreign Trade Opportunity number.

Norway—Cars and supplies. Quotations should be f. o. b. New York. Terms, cash against documents at destination. No. 29403.

New Zealand—Cars, accessories, trucks; electric trucks, ½ to 7-ton; tractors. No. 29420.

Uruguay—Cars and motorcycles. No. 29423.

Switzerland—Cars, bicycles and pneumatic tires. Correspondence may be in English. No. 29434

Italy—Trucks, 5- to 7-ton, heavy construction. High grade passenger cars. Correspondence should be in Italian or French. No. 29440.

Brazil—Rubber tires. Correspondence may be in English. No. 29443.

France—Tractors. Terms cash. Correspondence in French. No. 29448.

Gillett Products to Have Plant

HOWARD CITY, MICH., May 26—The Gillett Motor Products Co., recently organized to make automobile parts, is breaking ground for a new steel and concrete manufacturing building.

E. M. Landis Co. Newly Incorporated

TOLEDO, May 24—The E. M. Landis Co. has been incorporated to take over the plant and business of E. M. Landis at 6 North St. Clair Street, and to manufacture a kerosene carbureter and automobile lock. The officers of the new company are: President, E. M. Landis; vice-president, Eugene Rheinfrank; secretary, C. E. Shanteau; treasurer, A. J. Hilt. The latter two gentlemen are the new members of the firm. The company will also continue to sell and repair gas engines, trucks and farm machinery.

National Tool Becomes Bluebird

ST. LOUIS, May 23—The National Tool & Manufacturing Co., maker of Bluebird products, has changed its name to the Bluebird Manufacturing Co. to more closely identify itself with its products.

India Tire Dividend

India Tire & Rubber Co., Akron, 2 per cent quarterly dividend on common, 1¾ per cent on preferred, declared payable July 1.

Router to Make Tools

OSHKOSH, WIS., May 26—The Router Mfg. Co. has been organized with a capital stock of $100,000 to engage in the manufacture of tools, metal goods, hardware, motor car accessories and similar goods. William P. Casey, E. G. Race and James C. Casey appear as incorporators.

To Reintroduce Townsend Highway Commission Bill

WASHINGTON, May. 24—The reintroduction of the bill providing for the establishment of a Federal Highway Commission to take over the control of the national highways, the distribution of funds under the Federal Road Aid Act and to co-operate with the state highway departments was forecast by a meeting held here recently by Senator Charles E. Townsend, father of the bill, with members of the automobile and highway industries.

The bill, which takes over the present duties and authority of the Bureau of Public Roads, Department of Agriculture, greatly enlarges the scope and duties of the road authorities.

Senator Townsend is the chairman of the committee on post offices and post roads. He informed the convention here to-day that he plans to again introduce the bill as soon as he can add various amendments and improvements that have been suggested since the last Congress.

Among those present at the meeting were Roy D. Chapin, president of the Hudson Motor Car Co.; W. O. Rutherford, vice-president of B. F. Goodrich Co.; S. N. Williams, president of the Highway Industries Association; Pyke Johnson, representing the National Automobile Chamber of Commerce and the National Automobile Dealers' Association; Windsor T. White, the White Co.; David Ludlum, president of the Autocar Co., and various road officials.

Auto Specialties Foundry in Operation

ST. JOSEPH, MICH., May 26—The first heat in the newly completed foundry of the Auto Specialties Co. was drawn May 17. The new foundry is now in full operation with enough orders ahead to keep it running several months.

Connor Physical Director for Goodyear

AKRON, OHIO, May 26—Edward Connor, former athletic director at Lincoln High School, is now with the Goodyear Tire & Rubber Co. as physical director. He was athletic director at Camp Sherman during the war with the title of major.

Official Decision for Disposal of U. S. Army Vehicles in France

Manufacturers Oppose Sale of American Cars and Trucks in France —Dealers and Users Anxious to Buy—Service Stations and Repair Shops to Be Disposed Of

PARIS, May 10 (Special Correspondence)—An official decision regarding the disposal of the American Army trucks and passenger cars now in France is expected within a few days. At the end of December, 1918, the Army possessed 7575 passenger cars and 32,500 trucks. Only a small number of these is required for the Army of Occupation, and the rest must be disposed of in Europe or returned to America. This week the Liquidation Board prepared a detailed statement of automotive material no longer required by the army and submitted the same to the French Government, which alone has authority to say whether the material shall remain in France or not. It is hoped that the French reply will be received early, as the clearing up of this question will permit the Americans concerned to return home.

The situation is rather peculiar. French automobile manufacturers are bitterly opposed to any American army cars being allowed to remain in France, and are bringing the greatest possible pressure to bear on the Government to force their return to America. They maintain that if it is necessary to sell these vehicles in France, the purchasers should be called upon to pay the 70 per cent import duty which is now in vogue, not on their present value, but on the original value of the cars and trucks.

Dealers and users, on the other hand, are just as earnest in their endeavors to buy this army material. One of the officers of the Liquidation Board said: "Buyers are literally shaking good money in our faces in order to get delivery of these automobiles."

Offers are coming from all quarters and from men with the best financial backing who want to buy in big quantities. No offers can be accepted, however, until the French Government decision has been rendered as to the conditions under which the material shall be disposed of.

It is stated that the Army has neither Dodges nor Fords for sale, all those now in hand being required for the Army of Occupation. The only other car of which large numbers exist in France is the Cadillac; but while this has an excellent reputation, it is too powerful a car and has too high a gas consumption to suit the average purchaser of used cars in France.

Some of the American army vehicles have already been sold to Allies other than France, who are in urgent need of them. A number of trucks has gone to Roumania, Serbia and Belgium. In addition, the Reconstruction Department of the French Government has taken for its own use some American army trucks.

When these purchases have been made, the officers of the Liquidation Board have insisted on sufficient spare parts being taken to keep the vehicles in efficient service for at least 6 months. This has been done in an unofficial manner in order to protect the interests of the American manufacturer. Nothing could be more disastrous to the reputation of the American automotive industry than to allow trucks to go to foreign countries without any means of maintenance.

In addition to the vehicles, there are large service depots and repair shops to be disposed of. The most important of these is the Reconstruction Park at Verneuil. This place has big machine shops and immense stocks of spares, including 146,000 solid tires. Owing to the shortage of buildings, these tires had to spend the winter out of doors without protection and have suffered a little in consequence. Probably they will be sold with the trucks, for they are inch sizes and could not be used on European vehicles.

Numerous rumors have been afloat regarding the disposal of the Verneuil shops. One of the most persistent is to the effect that the White Co. had an option on the entire place. Inquiries at headquarters show that while the White people are interested, no option has been given to them.

New British Engine Combines Internal Combustion and Steam Principles

LONDON, May 27—A new design of liquid fuel engine, for which a thermal efficiency higher than that of the Diesel is claimed, was described in a paper before the Society of Arts yesterday afternoon. It is the invention of William Joseph Still, who spent the past eight years on its development.

With the ordinary internal combustion engine a greater amount of heat than is converted into useful work passes into the cooling jacket and is dissipated by the radiator. Still recovers some of this heat by making the cylinder jacket into a steam boiler and using the steam generated therein in the same cylinder in which the combustible charge is expanded, but at the opposite end of the piston. The engine is thus double-acting and, inasmuch as there is always a store of energy in the steam and hot water of the boiler, the engine cannot be stalled by temporary small overloads.

It appears that the engine is intended mainly for marine propulsion where the use of large units would increase the importance of any saving in fuel and minimize the objection to increased complication of plant. It is claimed that a marine propulsion set weighs 20 per cent less than a geared steam turbine plant, and uses 2000 tons less fuel for a double journey lasting 1000 hours, this comparison being based evidently on a vessel of given tonnage and speed.

C. C. Hanch Returns

NEW YORK, May 28—C. C. Hanch, secretary of the National Automobile Chamber of Commerce, returned Saturday from a 4 months' investigating trip in European countries. Mr. Hanch is engaged in preparing reports of his investigations abroad.

Schwab Elected President of Adams-Williams

NEW YORK, May 27—F. C. Schwab, who resigned as president of the Adams-Williams Manufacturing Corp. to enter government service, was re-elected to that position at a special meeting of the directors of the company. S. H. Crittenden, who also returned from service recently, was elected vice-president. Leo W. Schwab was re-elected secretary and treasurer. Plans have been completed to enlarge factory space and increase production this year.

Wright-Fisher Engineering Co. Formed

DETROIT, May 24—The Wright-Fisher Engineering Co. has been formed here by James A. Wright, W. Ruben Fisher, W. E. Jominy, Albert Harwith, William J. Kurth and L. F. Merritt, all of whom were engaged until recently in the Bureau of Aircraft production. The company will engage in the designing of tools, dies, jigs, fixtures, special machinery, automatic machinery, heat treating equipment, etc.

Increased Production for Marshall Starter

ADRIAN, MICH., May 26—The Adrian Castings Co. is increasing its working force and the output of the Marshall automobile starter. The Marshall starter is the invention of Hal Marshall of this city, and was manufactured for over a year by the Page Steel & Wire Co. before it was taken over by the Adrian Castings Co. The latter is preparing to produce 200 starters per day.

John Bohnet to Make Truck Bodies

LANSING, May 26—The John Bohnet Co. has increased its capitalization $100,000. The company will enter the truck body field, making a specialty of hearse, delivery and ambulance bodies.

Rubber Association to Study Taxes

AKRON, May 26—The Rubber Association of America has appointed a committee of seven to make a study of the new federal tax on tires, tubes and accessories. Among those on the committee are F. C. Van Cleef of the B. F. Goodrich Co.; B. M. Robinson, Firestone Tire & Rubber Co.; and C. L. Landon of the Goodyear Tire & Rubber Co.

New members of the association just admitted include H. J. Adams, C. R. Quine, Akron Equipment Co.; T. M. Gregory, Jr., M. D. Kuhlke Machine Co.; John Hadfield, Lincoln Rubber Co.; Leo Meyer, A. P. Whetlen and F. E. Holcomb of the J. K. Williams Foundry & Machine Co.; Paul E. Collette of the Oak Rubber Co., and Joe S. Benner of the Electric Rubber Reclaiming Co.

N. A. C. C. Meetings to Discuss Problems of Industry

NEW YORK, May 26—The National Automobile Chamber of Commerce has arranged a number of special meetings to be held at the general headquarters in New York during the week of June 2, to deal with problems arising in the industry. There will also be meetings at Washington.

Following is the schedule of meetings:

June 2, 10 a. m., Washington, D. C.—Export Committee, J. Walter Drake, chairman, for conference with officials of Department of State and Department of Commerce on foreign trade limitations.

June 3, 10 a. m., Washington, D. C.—Meeting of Tax Committee in connection with elimination of taxes on cars, trucks and parts.

June 4, 10 a. m., New York Headquarters—Directors' meeting.

June 4, 2 p. m., New York Headquarters—Meeting of Truck Committee, Windsor T. White, chairman.

June 5, 10 a. m., New York Headquarters—Annual meeting of members.

June 5, 1.30 p. m., New York Headquarters—Regular meeting of truck manufacturers, members of N. A. C. C.

June 6, 10 a. m.—Meeting of export managers, N. A. C. C., New York Headquarters.

Highways Committee to Study Short Hauls

WASHINGTON, May 26—The Highways Transport Committee, Council of National Defense, will make an intensive study of short haul problems at Boston, New York, Philadelphia, Pittsburgh, Baltimore, Washington, Atlanta, New Orleans, St. Louis, Chicago, Detroit, Cleveland, Omaha, Denver, Dallas, San Francisco, Los Angeles, Portland and St. Paul. The committee asks the co-operation of all manufacturers and dealers so it may obtain the maximum amount of data. Any information relative to the names and addresses of operators, number and capacities of trucks in use, routes and schedules and rates with copy of the tariff when it is available is desired. Such information should be sent directly to the Highways Transport Committee, Council of National Defense, Washington, D. C.

Haynes to Increase Capacity

KOKOMO, IND., May 26—The capacity output of the Haynes Automobile Co. will be increased to 15,000 cars annually, according to plans which were decided upon at a recent meeting of the directors of the company. To make this expansion possible the directors voted to construct a large new factory building and a forge shop and to increase the capital stock from $3,500,000 to $5,000,000.

A. G. Seiberling was elected second vice-president. He will continue as general manager. March Haynes, son of Elwood Haynes, was chosen assistant treasurer and secretary.

The new factory building will be 4 stories, 500 x 150 ft., adding 300,000 sq. ft. The building will be of fireproof steel and concrete construction, and will be used for assembling, trimming, painting and storage. It is estimated the normal output of the enlarged factory will be 50 cars a day. Work on the new building has been started.

"Wilson-Built" Trade-Mark

DETROIT, May 26—The C. R. Wilson Body Co. will trade-mark with the Wilson triangle, containing the words "Wilson-Built," all bodies turned out by its plant.

Suggestions Asked as to Form of Census of Automotive Manufactures

Tentative Form for General and Supplemental Information—Bureau of Census Anxious for Suggestions and Criticisms

WASHINGTON, May 24—A survey of the manufactures of 1919 will be taken by the Bureau of Census, Department of Commerce, in connection with the next census. A blank form has been prepared for both general and supplemental information, the latter including the kind, quantity and value of manufactured product, and will be mailed to the manufacturers of the automotive industry in December of this year.

The form which is presented herewith is tentative and subject to revision, and the Bureau of Census will welcome every suggestion from the industry that will be helpful to a better presentation of the statistics and which will be in harmony with the bookkeeping methods of the manufacturers.

All recommendations and criticisms may be addressed directly to the Chief Statistician for Manufactures, Bureau of The Census, Department of Commerce, Washington, D. C.

3. Remarks:

Seventh Foreign Trade Convention Next May

NEW YORK, May 26—The Seventh National Foreign Trade Convention is scheduled to be held in San Francisco on May 12-15, 1920. This will be the first convention of the National Foreign Trade Council to be held on the Pacific coast, and will give special opportunities for the study of export possibilities in South America, China, Japan, Siberia, India, and Australasia.

May Make Licenses Valid Everywhere

WASHINGTON, May 23—A bill has been introduced in Congress to allow anyone qualified to drive an automobile in his residential state to go into another state for business or pleasure without taking out an additional license or tag or paying an additional tax. It is also provided that no owner of an automobile who has complied with the laws of his own state shall be required to make any additional registration or pay any additional tax to operate an automobile in any other state. The bill, which was presented by Senator Pittman of Nevada, was referred to the Committee on Interstate Commerce.

Government to Standardize Army Tractors

DETROIT, May 26—The Government has established at 1492 Federal Avenue an experimental station for artillery tractors which is in charge of Don Ferguson, consulting engineer. Associated with Mr. Ferguson at the station is William H. Oliver, former chief engineer of the Hyatt Roller Bearing Co. The station will devote its efforts to standardizing the army tractor. There is a large corps of regular army men, enlisted men and civilians.

Grand Central Palace for Commercial Exhibits

NEW YORK, May 24—The Grand Central Palace will be used as a show place for all sorts of manufactured products when it is returned from service as a base hospital on September 30. The Merchants and Manufacturers Exchange will take it over as a commercial exhibit building, and plans for reconstruction of the interior to make it suitable for this purpose are under way. It is a 12-story structure, each floor having approximately 60,000 sq. ft. of floor space.

The four lower floors will continue to be used for annual expositions, and the eight upper floors will be divided among the industries for permanent showings of their products, to be opened beginning Oct. 15. Some of the industries will occupy an entire floor, such as the International Farm Tractor and Implement Exchange, to occupy the sixth floor. Detailed information may be obtained from the Merchants and Manufacturers Exchange, Room 421, 405 Lexington Avenue.

Whitcomb Heads Kenosha Wheel

KENOSH, WIS., May 26—The Kenosha Wheel & Axle Co., organized with a capital stock of $500,000, as already reported, has completed its organization by the election of the following officers: President, James A. Whitcomb; vice-president, Adolph Epstein; secretary and treasurer, Lloyd E. Wood; directors, Martin P. Winther, F. E. Dunnebacke. Mr. Whitcomb is the owner of the Whitcomb Tool & Machine Co., Kenosha, which merges its business with the new concern. Mr. Wood was associated with the Mitchell Motors Co., Racine. The former plant of the Winther Motor Truck Co., Winthrop Harbor, Ill., has been acquired by the new company and is being equipped for use until a new manufacturing group is built in Kenosha.

Sunbeams Barred From Race

NEW YORK, May 26—The two Sunbeams brought over for the Indianapolis 500-mile race on May 31 by Louis Coatalen, their designer, have been barred from the event because the machines were found to be oversize with a piston displacement greater than that permitted by the American Automobile Association. This means that Dario Resta and Jean Chassagne, who were to have piloted these cars in the 500-mile Victory sweepstakes, have lost their chance to take part.

Discontinue Motor Transport Shipments to A. E. F.

WASHINGTON, May 24—Cables from the A. E. F. have ordered cancellation of all shipments of motor transport corps supplies to France. The supplies now on hand in Europe are sufficient to meet the requirements until evacuation is completed.

$300 Fee for 7-Ton Trucks Proposed

Charge from $10 Up Recommended by Massachusetts Legislature Considered Prohibitive

BOSTON, May 26—The Roads and Bridges Committee of the Massachusetts Legislature has recommended registration fees for trucks that are regarded as practically prohibitive for the use of larger trucks. The report begins with $10 for 1-ton trucks and is increased to $50 for 4-tons, $200 for 6-tons and $300 for 7-tons.

The present fees are $5 for the 1-ton truck, rising gradually to $23 for 7-ton trucks. When the Truck Dealers' Committee was asked for suggestions, they recommended fees ranging from $10 for a 1-ton truck to $46 for a 7-ton. The Massachusetts Highway Commission outlined a scale of fees ranging from $10 for a ½-ton truck and $20 for a 1-ton to $260 for a 7-ton truck.

The controversy over the fees has had a material influence in retarding truck sales. Users now decline to buy heavy trucks until this question is settled.

The truck owners protested any increase, basing their objection on the fact that they pay heavy personal property taxes as well as registration fees. Truck owners did not at any time admit that the registration fees should be increased. The bill as drafted by the committee has been referred to the Committee on Ways and Means and the opponents plan that if they do not get a report to their liking in the committee they will carry it to the floor of the House.

One element entering into the present controversy is the fact that the Highway Commission is to be reorganized and this may change the general status of the proposed legislation.

Complete Airplanes Made by Mexican Government

WASHINGTON, May 27—The Mexican Government has established aviation shops, together with an aviation school, on the outskirts of Mexico City. Both the school and shops were opened in January under direction of the War Department. There are 40 airplanes in Mexico, 10 of which were constructed at the shops and the others assembled there.

The shops are equipped for the manufacture of complete planes, and the present capacity is placed at one airplane and six propellers per week, with facilities for increasing the propeller capacity to 40 per week. At first European and American engines were used entirely, but reports now indicate that engines are being manufactured at the shops. This engine, known as the Aztatl motor, is described as being 80-hp., 120 r.p.m., and functions perfectly at 2500 meters. Work is also being done, according to reliable reports, on an engine of 150 to 180 hp. Propellers of good quality are maufactured from mahogany and other native wood. The anahuac propeller, made of mahogany and "pople," functions perfectly at 2500 meters. It reached 1200 r.p.m. Steps have been taken toward the construction of bombs for airplanes and of bombing planes. The Government expects to build armored bombing machines this year.

Goliath Attains Record Height of 16,730 Feet

PARIS, May 10 (Special Correspondence)—Henry Farman's biplane, the Goliath, which for the past 3 months has been running between Paris and London, and Paris and Brussels, has established a height record of 16,730 feet with 25 persons aboard. This altitude was attained in 1 hr. 15 min.; the descent occupied 25 min. The Goliath, with its load, weighed over 4 tons, made up as follows:

	Lb.
25 passengers	3582
Airplane	4400
Gasoline	770
Oil	66
	8818

The Goliath is fitted with two Salmson star engines developing a total of 550 hp. During the record flight the engines were never run at their full power, in order not to subject the plane to undue strains. It is asserted that the pilot never made use of more than 360 hp.

This biplane has made two previous attempts at height records. On April 1 it attained an altitude of 20,670 ft., with 5 persons aboard, in 65 min., and 3 days later it rose to 20,340 ft. in 65 min. with 14 persons aboard.

Young Industries Gets Patterson Plant

HOLLY, MICH., May 23—The L. A. Young Industries, Inc., Detroit, at a receiver's sale, purchased the plant of the Patterson Manufacturing Co. here, and will start operating immediately. The company will make cushion springs for automobiles and 250 men will be employed. Plans for the building of 50 homes for the new workers are also under way.

New Automobile Signal Co.

GRAND RAPIDS, MICH., May 21—The Automobile Signal Co. has been formed with a $400,000 capital. Of the capital stock, $100,000 is preferred stock subject to redemption at par April 1, 1949, and the holder is entitled to an 8 per cent dividend. It is provided that the corporation may redeem the preferred stock on any dividend date at 105 per cent of its par value, plus accrued dividends. None of the common stock has been subscribed, but all of the common stock has been paid in through the receipt of United States and Canadian patents and the trade-mark registered in the U. S. patent office. The stockholders are Joseph Renihan, V. I. Cilley, and I. J. Cilley.

Program Outline for Pan American Meeting

Aviation Up for Discussion—All Aspects of Pan-American Trade to Be Considered

WASHINGTON, May 26—The Pan-American Commercial Conference will open here on June 2 at 4 p. m. instead of June 3 at 10 a. m. as was first planned. The change has been made to allow certain speakers to attend who will be absent at the later days.

Aviation will be one of the topics discussed, particularly in its relation to Pan-American commerce.

Beginning June 3 at 9.30 a. m., and continuing thereafter with morning, afternoon and evening sessions, the conference will take up the following principal topics:

I—General Review of Pan-American Export and Import Situation.

II—Trading Methods for Both Exports and Imports, subdivided into:
- (a) Business ethics,
- (b) Merchandising,
- (c) Commission service and direct trade,
- (d) Export and import combinations.

III—Shipping and Other Transportation, subdivided into:
- (a) Steamship lines and ships.
- (b) Other transportation, including airplanes as an aid to commerce.

IV—Financing Trade; Investments; Loans, Etc., subdivided into:
- (a) Banking,
- (b) Credits,
- (c) Investments, loans, etc.,
- (d) Government aid to commerce, including the War Finance Corporation.

V—Engineering Aids to Commerce, subdivided into:
- (a) Railways and highways,
- (b) Waterways and harbors,
- (c) Irrigation,
- (d) Sanitation.

VI—Parcel Post, Trade Regulations, Etc., subdivided into:
- (a) Parcel post,
- (b) Patents and trade marks,
- (c) Consular and other trade regulations,
- (d) Packing and insurance.

VII—Commercial Intelligence, subdivided into:
- (a) Advertising and publicity,
- (b) Newspapers and periodicals.

VIII—Educational and Social Auxiliaries to Commerce, subdivided into:
- (a) Vocational training,
- (b) Language study,
- (c) Exchange of students and professors,
- (d) General influences.

The governors of the various states have been invited to attend or send representatives. The conference will open on Monday afternoon with addresses by Vice-President Marshall, the Ambassador of Mexico, the Minister of Bolivia and others. Speakers on various topics at the following sessions include William C. Redfield, Secretary of Commerce; Dr. Carlos de Cespedes, Minister of Cuba; Dr. L. S. Rowe, Assistant Secretary of the Treasury; Don Julio Zamora, Financial Commissioner of Bolivia; Dr. José Santiago Rodriguez, Special Commissioner of Venezuela; Julius G. Lay, Foreign Trade Adviser of the State Department; Francisco J. Yanes, Assistant Director of the Pan-American Union; Don Ernesto Perez, Argentine Consul General of New York, and Dr. Burwell S. Cutler, Chief of the Bureau of Foreign and Domestic Commerce.

Wireless Telephony at S. A. E. Meeting

Connection Will Be Made Between Boat on Lake and Lecture Room—450 Reserved

NEW YORK, May 28—A demonstration and lecture on wireless telephony will be the feature on Tuesday evening, June 24, at the Summer Meeting of the Society of Automotive Engineers at Ottawa Beach. E. H. Colpitts, of the Western Electric Co., who has been identified with the development of wireless telephony, and who spent many months in France during 1918 on radio transmission, is preparing to give a combined lecture and demonstration that will occupy an hour to an hour and a half.

A high speed motor boat is being fitted with apparatus and the lecture room at Ottawa Beach will also be equipped so that all of those attending the lecture can listen to the conversation by wireless telephony between the demonstrator and the operator on the motorboat, which will be several miles out on Lake Michigan. In addition Mr. Colpitts will explain wireless telephony by means of many illustrations, still pictures, and various demonstrating apparatus.

One of the sessions will be given over to members of army and navy departments, who will tell to members of the S. A. E. what their plans are with regard to the future, so that industry may be kept as closely in touch with government as possible. Already the Aircraft Department, Ordnance Department and Motor Transport Departments have agreed to send representatives to Ottawa Beach for this express purpose. Not only will they outline the program of these departments but will answer questions.

The forenoon, given over to the future passenger car, promises to be of unusual interest. Already seven or eight leading engineers have prepared their views on the future passenger car, and it is expected that upwards of 50 or more engineers will express their opinions on this subject during the session given over to it.

It is very probable that an exhibit of captured German trucks will be one of the features of the meeting. These trucks are already on their way to America and it is expected that a portion of them will be on hand at Ottawa Beach.

Four hundred and fifty reservations have been made at the hotel for the entire 5 days of the meeting. Reservations are coming in at the rate of practically 30 per day.

—

Advance Pump Additions

BATTLE CREEK, May 26—The Advance Pump & Compressor Co., Battle Creek, is adding to its plant and equipment. Building additions and installations of machinery aggregating $75,000 in value are being completed.

Overland Strikers Resume Work

Thirty Departments Opened Monday—Number of Men Back Is Disputed

TOLEDO, OHIO, May 27—The Willys-Overland Co. resumed operation in 30 of its departments yesterday. Thirty more departments opened to-day and to-morrow will see the remaining units in operation. In spite of the strike, which has been in progress for 3 weeks and the fact that the plant was heavily picketed by the strikers, the returned workers were not molested. There was no disorder. All gates to the plant were heavily guarded by police, special deputies, Overland guards and United States troops. Two hundred soldiers, members of the 135th Field Artillery and 147th Infantry, under command of Colonel Loyd W. Howard, are on duty.

Car Production Curtailed

No cars were made yesterday, the departments in operation producing parts only, and it is doubtful if the company will get back into production this week. Vice-President Clarence A. Earl was unable to give an estimate of the number of men returning to their posts. From the number of men still out, it is apparent that the trouble is far from settled, and it will take the company 2 or 3 weeks to get back into reasonable production. Practically all the machinists are holding out.

Workers Not Interfered With

When the company closed its doors 2 weeks ago it was producing 435 cars daily. In a statement to AUTOMOTIVE INDUSTRIES, Mr. Earl said: "We are very much pleased with the result of the first 2 days' operation. I cannot tell how many men have returned. Workmen who quit because of fear have been given ample protection."

Joseph D. LaDonde, head of the workers' wage committee, said: "Not over 800 men went to work Monday. Of this number about 350 were foremen and assistant foremen. No attempt was made by pickets or union supervisors to interfere with the returning workers."

—

Henry Ford & Son Resume

DEARBORN, MICH., May 28—Henry Ford & Son, which closed for inventory the first of the month, has resumed operations. Completed tractors will be coming through again in quantity by June 1.

—

Wright-Martin Merging With International Motors

NEW BRUNSWICK, N. J., May 27—The Wright-Martin Aircraft Corp. and the International Motors Corp. are formulating plans by which the two companies will be merged. All plans are tentative and no details can be obtained.

General Motors Officers Visit Michigan Plants

DETROIT, May 26—A delegation of officers and directors of the General Motors Corp. and du Pont de Nemours Co. visited this city last week for an inspection of the corporation's plants in Michigan. The executives, headed by President W. C. Durant, spent one day each in Detroit, Pontiac, Saginaw, Flint, and Lansing.

The visiting executives included Irenee du Pont, Felix du Pont, Eugene du Pont, E. E. du Pont, H. F. du Pont, J. A. Haskell, H. G. Haskell, William Coyne, H. F. Brown, F. Donaldson Brown, F. W. Pickard, F. G. Tolman, H. F. Pierce, J. J. Raskob.

—

Horace Mills, director of sales of the Stroh Casting Co., Detroit, has resigned and will be associated with Walter O. Adams in a new enterprise. **E. Betts**, foundry engineer, has also resigned to become interested in the same project.

—

Benjamin Briscoe, president of the Briscoe Motor Corp., Kalamazoo, Mich., who is also a Lieutenant-Commander in the U. S. Navy, has just been made a Commander and has been taken from the retired list. He has been ordered to Great Lakes Naval Training Station and will again assume active duties.

—

J. G. Cashin, for four years with the Curtis Co., Detroit, has been made advertising manager of the Standard Motor Truck Co., Detroit.

—

George Ostendorf, formerly with the Tropical Paint & Oil Co., Cleveland, has joined the sales force of the Hilo Varnish Co., Brooklyn, N. Y., and will make his headquarters in Cleveland.

—

W. D. Hopson, who for three years represented the Studebaker Corp. of America as service supervisor in the Orient, has been appointed service representative for the General Motors Export Co. in the Far East. He expects to sail for Shanghai about June 15.

—

J. A. Teach, contracting, mechanical and structural engineer, is now at the New York office of the Minneapolis Steel & Machinery Co. C. W. Hadden continues as export manager.

—

T. C. Luce and **W. Storrie** have been added to the engineering department of the Apco Manufacturing Co., Providence. Mr. Luce for the past five years has been on the engineering force of the American Chain Co. Mr. Storrie was one of the early designers of Argyll cars, made in Glasgow, Scotland.

—

Raymond G. Lambe, formerly on the purchasing staff of the Ford Motor Co., has been appointed sales manager of the Detroit Reamer Salvage Co.

Men of the Industry

Changes in Personnel and Position

Mahoney New Buda Sales Manager

HARVEY, ILL., May 24—J. P. Mahoney, for three years general purchasing agent of the Buda Co., has been appointed sales manager to succeed Lon R. Smith, who resigned.

—

Fred C. Young will be in charge of the Cleveland office of the Union Drawn Steel Co., Beaver Falls, Pa., which was recently opened at 608-610 Rockefeller Building.

—

Donald P. Hess, director of the Priorities Section of the Motors and Vehicles Division of the War Department during hostilities, has been appointed assistant factory manager of the Timken Roller Bearing Co., Canton, Ohio.

—

A. H. Jessup, a captain in the Sanitary Corps with the 77th Division, has received his discharge from service, and has returned as plant engineer to the Lakeside Forge Co., Erie, Pa.

—

A. J. Collins has been appointed advertising manager of the Ajax Rubber Co., New York. He was formerly assistant to the publicity manager of the Atlas Portland Cement Co.

—

A. R. Ruggles, vice-president and production manager of the Panhard Motors Co., Grand Haven, Mich., has resigned, due to ill health.

—

E. P. Barnett has been appointed sales manager in the Milwaukee territory for the Titan Truck Co., Milwaukee. He was formerly connected with the Sterling Motor Truck Co. and M. D. Newald & Co., Stewart distributers at Milwaukee.

—

E Leidich has been appointed foreign sales manager of the Columbia Motors Co., Detroit. He was formerly in a similar position with the Paige company.

—

William J. Moore, who has been director of purchases at the Fordson Tractor Co. almost from the time the company was organized, has resigned. His future plans are not known.

—

Charles A. Sinclair, assistant secretary and treasurer of the Anderson Forge & Machine Co., Detroit, died suddenly of pneumonia on May 22. He was 45 years old and was connected with the company for 8 years. He leaves a widow and two sons.

Pope to Represent S. A. E. at Engineering Conference

NEW YORK, May 23—At the May meeting of the Society of Automotive Engineers, Metropolitan Section, held at the Automobile Club of America last night, N. B. Pope was appointed a delegate to a conference of representatives of New York sections of engineering societies. For the nominating committee of the S. A. E., the Metropolitan Section appointed C. F. Scott as first choice and H. W. Slauson as alternate.

C. F. Scott spoke on preparations for the summer meeting at Ottawa Beach, Mich., and urged everyone to attend. The paper of the evening, on Four Wheel Drive Trucks, is abstracted elsewhere in this issue.

—

Frank H. Dewey, for some time truck engineer for the Packard Motor Car Co., Detroit, is now associated with the Horizontal Hydraulic Hoist Co., Milwaukee, as sales engineer, and has opened a Detroit office for the company.

—

Bruce E. Anderson, formerly with the Ideal Engine Co., has been appointed general manager of the Lansing Body Co., Lansing, succeeding Frank Thoman, who has retired from the managership, but retains his position on the board of directors.

—

Glenn H. Harker, who spent 21 months in France, has now become manager of the Falls Tire Co., Detroit. He was connected with the Federal Tire & Rubber Co. when he enlisted.

—

Harry S. Finkenstadt, who enlisted in the aviation corps shortly after the United States' entry into the war, has recently been honorably discharged and returned to Detroit as western sales agent of the Carbon Steel Co., Pittsburgh.

—

L. R. Scafe, who was comptroller of the Dayton-Wright Airplane Co., Dayton, is secretary and treasurer of the American Finance Investment Co. of that city.

—

John H. Hertzler, who was with J. S. Bretz, has been appointed sales manager of the Cleveland Worm Gear Co., Cleveland.

—

Miss Jelliffe Leaves S. C. Johnson & Son

RACINE, WIS., May 23—Miss Sarah Jelliffe, who has been advertising manager of the S. C. Johnson & Son Co. for a number of years, is resigning to become connected with the Western Advertising Agency.

—

Jordan Erecting New Buildings

CLEVELAND, May 26—The Jordan Motor Car Co. has commenced work on several additions to its factory, which include a power plant, assembly plant, office building, japanning plant and engine test building.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

M. & S. Now Powrlock

CLEVELAND, May 26—The M. & S. Corp., which recently moved here from Detroit, has changed the name of its product from the M. & S. differential to Powrlock, and has also changed its corporate name to the Powrlock Co. M. T. Walker, formerly vice-president and general manager of the Walker-Weiss Co., is president of the new concern. Other officers are: sales manager, L. O. Haskins; factory manager, R. S. Townsend; chief engineer, R. H. Goodrich. A new plant is in operation which will give increased manufacturing facilities.

Kalamazoo Sheet Metal Co. Organized

KALAMAZOO, May 24—The Kalamazoo Blow Pipe & Sheet Metal Co. is a new concern organized by H. F. Brundage and Harry Baird. It will act as sheet metal engineer and contractor, and render specialist service in installing exhaust and blow piping, heating and ventilating, air drying and cooling systems.

Chicago Pneumatic Tool Coming East

NEW YORK, May 23—The Chicago Pneumatic Tool Co. will put up a 10-story brick building here at 6-8 West 44th Street, and will move its general offices to this city from Chicago.

Buda Establishes Service Companies

HARVEY, ILL., May 24—The Buda Co. will establish Buda engine service companies all over the country. The first will be opened in Los Angeles, San Francisco, Seattle, and possibly Portland, Ore. The establishment of a service company in Kansas City will take care of the Middle West, and New York City will be the eastern headquarters.

International Corp. Groups Subsidiaries Under Allied Machinery Co.

NEW YORK, May 23—An increase in the capital stock of the Allied Machinery Co., bringing it up to $5,000,000, was made necessary by the decision of the American International Corp. to group all its machinery export selling subsidiaries under one head. The Allied Machinery Co. of America will thus become the parent organization of the Allied Machinery Co. de France and the Allied Machinery Co. d'Italia and of the Horne Co., Ltd., of Japan, purchased early in the year by the American International Corp. These companies will, however, retain their corporate entities.

The Allied Machinery Co. of America formed in 1911 was taken over in 1916 by the American International Corp. J. W. Hook is president in general charge of the business. Other officers are: Vice-presidents, F. A. Monroe, in charge of administrative affairs, S. T. Henry, in charge of sales and advertising, and T. G. Nee, who is at present in Japan, in the interests of the Horne Co., Ltd. R. P. Redier is general sales manager with headquarters in Paris.

The Detroit, a New Assembled Truck

DETROIT, May 24—Leonard B. Orloff Co., automobile distributer, will assemble a 1-ton truck bearing the name Detroit. The truck will be on exhibition at the Orloff salesrooms, 811-815 Second Avenue.

The truck is assembled almost exclusively of units turned out in local factories. The engine is a Continental model N; the frame is from the Detroit Pressed Steel Co.; the springs from the Detroit Steel Products Co.; the front axle is Timken and the rear, Russel; the clutch and transmission from the Detroit Gear & Machine Co. factories; the radiator is made by the Long Mfg. Co.; the steering is Gemmer; the wheels are made by the Hayes plants; the fenders and hood by the Motor Metal Products.

Kalamazoo Motors Takes Over Lane Truck

KALAMAZOO, MICH., May 23—The Kalamazoo Motors Corp. has been formed with a paid in capital of $250,000 to take over the business formerly conducted by the Lane Motor Truck Co. The officers of the new company are: President, H. A. Crawford; vice-president, C. J. Johnson; secretary, R. M. Gregory; treasurer, W. B. Milham; chief engineer and production manager, L. W. Coppock. The company has already taken possession of the Lane Motor Truck Co. building. The truck which will be made by the new company will be known as the Kalamazoo, and will come in three sizes, 1½, 2½ and 3½-ton models. The company plans an output of 1000 trucks a year.

Harroun Issues Additional Stock

DETROIT, May 23—The Harroun Motors Corp., because of its inability to secure an adjustment on a war claim of approximately $700,000, has just issued a call on its stockholders for funds, the basis being the purchase of additional stock at $5 per share. Lack of operating capital has prevented the Harroun company from getting into passenger car production, and drastic steps to re-finance it are now being taken. A committee representing Kansas City investors, who advanced $650,000 some time ago, is supervising affairs of the plant at Wayne.

The company, it is explained, exhausted its working capital through government work. The money received from shareholders will be needed in changing to a normal basis. The entire output now in contemplation has been sold to its distributers for five years.

Liberty Building New Plant

DETROIT, May 25—The new factory site for the Liberty Motor Car Co. comprises 12 acres, on which three principal buildings and a power house are being erected. The administration headquarters will front on Charlevoix Avenue, and will be 50 x 200 ft., of brick colonial construction. Production offices and display rooms will be on the first floor, and executive and sales offices on the second. The second building, 60 x 320, immediately behind the first, will include a service, experimental and closed body mounting department. Back of this will be the main assembly building, which is to be 120 x 600 ft., and power house will complete present plans.

Van Dorn to Put Up New Building

CLEVELAND, May 23—The Van Dorn Electric Tool Co. will erect a $100,000 4-story concrete manufacturing building. It will cover ground space 60 x 100 ft. with a 1-story addition 125 ft. deep.

Briscoe Devices Co. Succeeds Jackson Carbureter

JACKSON, MICH., May 24—The Jackson Carbureter Co., maker of Dave Buick carbureters, will be succeeded by the Briscoe Devices Co., and its product will be known as the Scoe carbureter. Frank Briscoe is president and general manager of the new concern. A. W. McCalmont, formerly with the Jackson Automobile Co. and the Briscoe Motor Co., and more recently an engineering officer in the Air Service in France, will be sales engineer.

KAENJAY Moves to New Jersey

NEW YORK, May 24—The Auto Leather Mfg. Co. has removed its plant and equipment from 21 Warren Street, New York, to a new building in Arlington, N. J. The company manufactures KAENJAY products.

Republic Opens Eastern Office

ALMA, MICH., May 24—The Republic Motor Truck Co., Inc., has opened Eastern headquarters in New York City with J. Martin Van Harlingen as district manager. John Sawan will be associated with Mr. Van Harlingen. He will make his headquarters at Pittsburgh, operating from the New York office.

Airplanes in Stewart Salesroom

BOSTON, May 23—C. E. West, manager of the Stewart Truck Co., has leased ground at Boxford, and six hangars are being erected, each of which will be 190 ft. long, 48 ft. wide and 48 ft. high. This will be used as training grounds for flyers and for an exhibition field. Mr. West has five machines in shipment and five more are to be delivered before June 15. He has one on exhibition in his salesrooms, where he will also keep a stock of parts. The machines are of the Curtiss JN-4 type, each with a 90 hp. engine. They were used by the Canadian government. One sale has been made.

24,199 War Contracts Cancelled

Claims for $150,000,000 Are Awaiting Examination and Adjustment by War Department

WASHINGTON, May 28—The War Department has cancelled 24,199 contracts to date since the signing of the armistice, of which 15,756 have been finally disposed of by release, supplementary agreement or award. In addition, definite agreements have been reached on 2500 others, and of those remaining all have been taken up by the Claims Board and are in process of examination and verification. A total of $150,000,000 of claims has not yet been formally presented because of their extent and complexity. These facts about the war contracts were revealed to-day in a report made by Assistant Secretary of War Benedict Crowell to Secretary Newton D. Baker.

It is estimated that the total cost to complete those contracts that have been eliminated would have been $3,600,000,000, and this figure has been reduced by the termination of the orders to claims amounting to $700,000,000. Up to date $153,476,000 has been awarded and $125,000,000 paid.

Following the passage of the act authorizing payment of informal contracts, and up to May, 17,568 awards were made under the law, including a total of $38,081,623 to be paid, of which $33,596,168 has been paid. The total number of claims filed under the act amounts to 2844.

Outlining the methods of settlement, the report states that where performance of a contract was curtailed adjustment was effected by agreement as to the extent of the curtailment, the contractor accepting a reduced order in lieu of the original one, and payments in addition to those for completed articles being only nominal.

Where the contractor made expenditures or commitments on the uncompleted portion of the contract he is reimbursed for the expenditures or commitments with an additional remuneration for the use of his capital and services that did not result in completed articles. In detail this settlement is made according to the following plans:

1. Reimbursement to the contractor for raw materials, direct and indirect, and component parts on hand in an amount not exceeding the requirements for the completion of the contract: Cost plus inward handling charges plus such portion of overhead as is directly applicable, less such sums as may represent the fair agreed value of all or any portion thereof, if the title and possession of the same are retained by the contractor.

2. Reimbursement to the contractor for articles in process, in an amount not exceeding the requirements for the completion of the contract: Cost of raw materials and labor plus such portion of overhead as is directly applicable, less such sums as may represent the fair agreed value of all or any portion thereof, if the title and possession of the same are retained by the contractor.

3. Payment to the contractor of a fair and equitable remuneration (1) for expenses and services of the contractor in connection with the items included in paragraph 1, but not to exceed interest at 6 per cent per annum on the capital invested therein, or, if the capital was borrowed, interest at the rate paid by the contractor; and (2) for expenses and services of the contractor in connection with the items included in paragraph 2, but not to exceed 10 per cent of the cost thereof.

4. Reimbursement of the contractor for such amounts as are properly paid by him in the adjustment and termination of unperformed sub-contracts and unperformed commitments for supplies which were properly entered into or made in connection with the performance of said original contract.

5. Reimbursement to the contractor for pay rolls and expenses paid or incurred with the approval of the contracting officer, or properly paid or incurred without such approval, for the custody and protection of property since the date of suspension above recited and pending final settlement.

6. Reimbursement to the contractor where special facilities were properly provided in connection with the performance of the original contract, necessity of which was contemplated by the contractor and included in his estimate of cost at the time the original contract was made, of such portion of the cost thereof as would reasonably have been recouped had the uncompleted portion of the original contract been performed.

7. Payment to the contractor of such additional sums, if any, as the Secretary of War may deem necessary fairly and justly to compensate the contractor for expenditures, obligations, and liabilities necessarily incurred, including work, labor, and service necessarily rendered, under the original contract or in preparation for the performance thereof, or under this supplemental agreement.

Explaining the task of settling the huge number of contracts, the Assistant Secretary stated that many contracts involve the history of a vast amount of material, complicated questions of the apportionment of overhead and the determination of the contractor's own obligations on his commitments on his sub-contracts which he has had in turn to curtail by reason of the termination of his contract by the War Department. In some prime contracts the sub-contracts run into the hundreds in number, and each must be verified by the department before settlement is made. Because of this the local bureaus were established in 34 sections of the country to first handle the claims before they were transmitted to Washington.

Racine-Sattley Will Put Up Engine Plant

SPRINGFIELD, ILL., May 24—The Racine-Sattley Co. has purchased land adjacent to its present site and will erect a $300,000 plant for the construction of gasoline engines from 1½ to 15 horsepower. Employment will be given to 600. It was planned to construct these buildings two years ago, but postponement was forced by the war.

Post Tractor Factory

CLEVELAND, May 15—The Post Tractor Co. has taken a 10-year lease on a structure to be erected as the first unit of its tractor plant. It will be increased in size as business permits.

Detroit Axle Bought by Puritan Machine

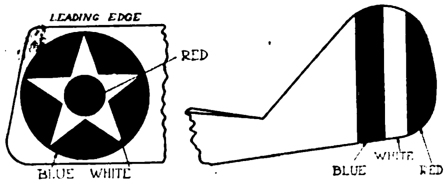
DETROIT, May 23—The entire stock and equipment of the Detroit Axle Co. has been purchased by the Puritan Machine Co.

Tower Truck Enlarging Plant

GREENVILLE, MICH., May 24—The Tower Motor Truck Co. has increased its capitalization from $200,000 to $500,000. New buildings will be erected at once to accommodate production increases on both the 2- and 3½-ton models.

New Insignia for U. S. Military Airplane

War and Navy Departments Authorize Change in Emblems for Wing and Rudder



Wing Insignia *Rudder Insignia*

WASHINGTON, May 24—The distinguishing insignia on American aircraft has been changed by order of the War and Navy Departments and will hereafter be a red circle inside of a white five-pointed star inside of a blue circumscribed circle. The circumference of the inner circle will be tangent to the lines forming a pentagon made by connecting the inner points of the star. The inner circle will be red, that part of the star not covered by the inner circle, white, and that part of the circumscribed circle not covered by either the inner circle or star will be blue.

The insignia is to be placed on the upper and lower surfaces of the upper and lower planes of each wing so the circumference of the circumscribed circle will be tangent to the outer tips of the planes. One point of each star must be pointed directly forward and the diameter of the insignia which can be either painted on or applied by decalcomania transfer, must be 60 in.

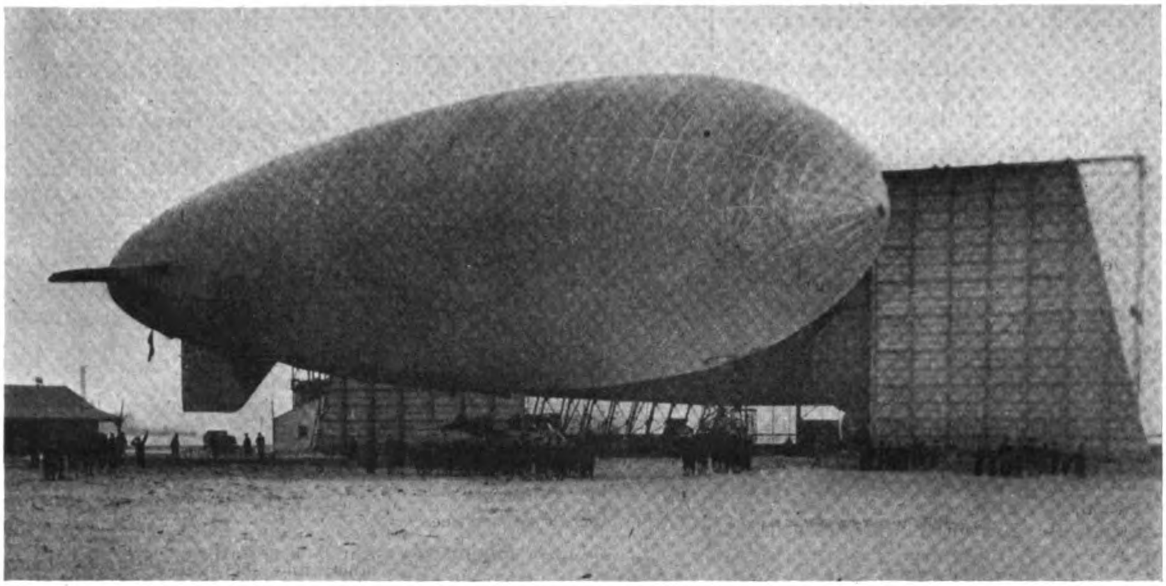
The rudder insignia will be three equally wide bands, red, white and blue. Both sides of the rudder, in the rear of the rudder post, will be striped parallel to the vertical axis of the plane, with the blue stripe nearest the rudder post, the white in the center and the red at the tail of the rudder.

Two Companies Under Bates Machine & Tractor Co.

JOLIET, ILL., May 23—The Bates Machine & Tractor Co. is the successor to the two merged firms of the Bates Machine Co. and the Joliet Oil Tractor Co.

New Steam Carbureter on Market

DETROIT, May 24—The Security Sales Co. is marketing a steam carbureter operating on any gas or kerosene engine for cars, trucks and tractors. According to the company, the water taken from the motor drips into the valve, where it is converted into steam, then uniformly injected into all cylinders by operating the control from the dash or steering column. The extra hydrogen from the steam gives perfect combustion, it is said. The company is now getting into production on a fair scale.



C-1
The type of dirigible now used by the Navy

Fleet of Dirigibles for Navy Recommended by Navy Board

WASHINGTON, May 24—The construction of a fleet of dirigible aircraft for the Navy is expected to be recommended by the General Navy Board in its report to Secretary Daniels within a few days. As a result particularly of the NC seaplane flights, and also because of other general investigations and experiments, the board believes that a great part of the future aerial expansion will include dirigibles. The opinion prevails here that this aircraft can make the flight across the Atlantic with heavy loads and are safer because they can remain in the air indefinitely while any mechanical damage is being repaired.

Secretary Daniels says that in his opinion the Navy should make no effort toward any large aerial expansion during the next year or two but should experiment to improve existing types. He anticipates further flights similar to the transatlantic attempt as new airplanes and dirigible aircraft are developed. He pointed out that the transatlantic flight had already shown defects in the NC seaplanes which, he said, are now far in advance of the development along this line reached by any other country.

It is expected that the naval bill which was lost in the filibuster of the last Congress, and which contained an appropriation for $10,000,000 toward the development of dirigible and other lighter-than-air machines, will be re-introduced in this special session.

Chicago-Cleveland Air Mail Successful

WASHINGTON, May 23—The air mail service established between Chicago and Cleveland on May 15 has had an unusual record for its first week of operation. In the 7 days 4160 miles were flown out of a possible 4480, and 28 trips accomplished out of 30, making a score of 93⅓ per cent.

There were no forced landings, but a 43-mile gale made the trips impossible one day. A total of 87,200 letters were carried west from Cleveland and 74,600 east from Chicago. The average flying time from Cleveland to Chicago was 3 hr. 40 min., and from Chicago to Cleveland 3 hr. 20 min., the difference being due to prevailing head winds. The best time made was on one trip from Chicago to Cleveland when the 325 miles were traveled in 2 hr. 48 min., and the longest trip was 4 hr. from Cleveland to Chicago. The rebuilt De Haviland fours are being used, equipped with Liberty engines. These have a mail carrying capacity of 400 lb. each.

Dallas-Boston Flyers Continue Flight

WASHINGTON, May 23—The six De Haviland airplanes flying from Dallas to Boston are continuing their flight according to schedule. Following is the route traveled:

May	From	To	Miles	Min.
15	Dallas	Oklahoma	208	105
17	Oklahoma	Camp Funston	300	170
20	Camp Funston	Topeka	60	45
		Total......	568	320

Col. H. B. Claggett, commanding the flight, has received requests to make several stops en route to Boston and will give them favorable consideration if landing facilities are adequate. Capt. W. H. Chandler, the automobile racer, who tested the first Liberty motor; Lieutenants J. E. Duke, Jr., R. F. Midkiff and W. T. Campbell, well-known stunt fliers, are in this service. During the flight a record will be made of the condition of land passed over, photographs taken, and emergency and regular landing fields noted.

Wright Field Re-Leased

WASHINGTON, May 26—The Wilbur Wright aviation field at Dayton has been re-leased by the War Department and will be used as a permanent storage and training depot. The field comprises 1100 acres.

Allied Planes Double Number Controlled by the Enemy

WASHINGTON, May 23—The Allies had 5972 airplanes at the French-Belgian front on Nov. 11, 1918, when the armistice was signed, as compared with 2730, the total number controlled by the enemy. The balloon strength of the enemy, however, totaled 170, as against 144 of the Allies.

France had the greatest number of planes with an aggregate of 3321; the Germans, 2730; Great Britain, 1758, and the United States, 740. Italy controlled 812 planes over her front, against 622 under the Austrian forces. Following is the tabular comparison showing the number of planes at the fronts when the armistice was signed:

French-Belgian Front	Number of Planes
France	3321
Germany	2730
Great Britain	1758
United States	740
Belgium	153
Total Allied	5972
Total Enemy	2730
Italian Front	
Italy	812
Austria	622

Following is the comparison of balloon strength:

French-Belgian Front	Number of Balloons
Germany	170
France	72
Great Britain	43
United States	23
Belgium	6
Total Allied	144
Total Enemy	170
Italian Front	
Italy	32
Austria	26

Air Service Studies Meteorological Conditions

WASHINGTON, May 26—That the upper currents of air run parallel to isobars was discovered in recent studies of currents and meteorological conditions by the Army Air Service in Nebraska, Arkansas and Missouri, when balloon

ascensions were made for this purpose. Two 35,000 ft. hydrogen filled balloons started at the same time, one maintaining an altitude of 5000 ft., the other 10,000 ft. The balloon at 10,000 ft. rose at 10.30 p. m. at the U. S. Army Balloon School, Ft. Omaha, Neb., and landed at 1.30 p. m. the following day at Arcola, Miss. The lower altitude balloon remained in the air 16 hr. and landed at Little Rock, Ark.

71.3 Per Cent Casualties Among French Aviators

PARIS, May 10—During the first six months of 1918 casualties among French air pilots and observers attained 71.3 per cent. This included 16 per cent killed, 25.8 per cent wounded and 29.4 per cent missing. Of these latter 70 per cent were afterward reported killed. In aerial flights 116 pilots were killed, and 218 by accident. In comparison with this it may be stated that the infantry during the same period lost only 51 per cent. Gunners, bombers and mechanics are not included in the figures of losses.

Experimental Station for Tractors

WASHINGTON, May 24—The Mexican Government has granted a concession of 247 acres to a Mexican citizen at Mazatlan and as much more ground as may be necessary at Ose, State of Sinaloa, where an experimental farm will be established and American manufacturers can demonstrate their tractors at a nominal cost. The plan is to promote the sales of American tractors and farm implements and educate the people in modern farming methods. There are no Mexican import duties on tractors, and it is stated that any farmers taking advantage of the offer will be exempt from all local taxes. The soil offered for experiment is level and fertile, and during the dry season can be irrigated from the Quila River.

Huge Increase in Exports

WASHINGTON, May 23—April exports surpassed previous high records by nearly $100,000,000, according to total figures announced to-day by the Bureau of Foreign and Domestic Commerce, Department of Commerce.

Exports for the month totaled $715,000,000, as compared with $623,000,000 for January, the previous high mark. For March of this year the total was $605,000,000, and for April a year ago $501,000,000. For the ten months ended with April the exports were valued at $5,705,000,000, as against $4,884,000,000 for the corresponding period last year.

Imports for April totaled $273,000,000 in value, a gain of $5,000,000 over the $268,000,000 announced for March and a decrease of $6,000,000 as compared with the $279,000,000 for April of last year. Imports for the ten months ended with April are put at $2,474,000,000, as compared with $2,362,000,000 for a similar period in 1918.

Ford Enters Denial In Infringement Suit

Thomson Spot Welding Alleges Illegitimate Use of Patent Welding Device

DETROIT, May 23—The Ford Motor Co. has been charged by the Thomson Spot Welding Co. of Lynn, Mass., with infringement upon the patents held by the Massachusetts firm on an electric welding device which the plaintiff alleges is being used in the Ford plants without their permission or license. Damages, which may total millions, are being asked by the complaining company, which has just filed its declaration of action in the Federal Court of Equity here.

The plaintiff alleges that on Jan. 3, 1903, Johann Harmatta, an Austrian, invented an electric spot welder and filed his application for a letters patent on the same. One month prior to applying for a patent, the inventor, in writing, assigned his invention and patent right to the Thomson Electric Welding Co. In December, 1912, a letters patent, No. 1,046,055, was issued. The Thomson company then granted exclusive rights under the patent to the Universal Electric Welding Co., New York, and the two concerns assigned their joint rights to the plaintiff, the Thomson Spot Welding Co.

In March, 1913, the Thomson company started infringement proceedings against the Barney & Berry Co., but after two years of litigation lost their action when the Massachusetts district court ordered the bill of complaint dismissed. The case was appealed, however, and on Oct. 5, 1919, the Circuit Court of Appeals reversed the decision and returned the case to the district court for a new trial. Here the district court declared an infringement and granted an injunction prohibiting the Barney & Berry Co. from further use of the patents and awarded costs and damages.

In charging Ford with infringement upon the patents, the Thomson company asks for a perpetual injunction and a temporary injunction prohibiting the use of this welding device during the pendency of the suit. Damages, royalty for past use, and costs are also asked.

The Ford Motor Co., in its answer, which also has been filed, admits the existence of the patents in question, also ownership of these patents, but denies that it used and sold articles whose manufacture was covered by these patents, and adds that it never practised the patented process. The Ford company also declares that it was never duly notified of an infringement and denies that it was a party to the Barney & Berry litigation.

The company further states that upon investigation it finds that the patents are invalid and that they had the right to use them if they desired, because 19 American patents were filed on a similar process prior to the filing of the original Thomson application in 1903. The first of these alleged priority patents was filed in 1886 and the last in 1909. Besides the American patents, similar devices have been patented in France, Great Britain and Germany. The defendant also declares that seven United States manufacturing concerns are daily using the same device and process, and asserts that the Thomson Spot Welding Co. is involved in a patent interference proceedings brought by Sebastian De Ferranti, who claims he holds patents on the same process, granted as early as 1900.

Mexican Employees for Ford Held Up

DETROIT, May 24—Henry Ford's delegation of Mexican workmen, which he was bringing here to take a course of instruction in tractor manufacture, has been held up at the border by order of the United States Immigration Department, and will not be permitted to enter the United States until Mr. Ford puts up a bond of $500 for each man.

There are 50 Mexicans in the party, all of them recommended as especially adapted for manufacturing by the Mexican government. It is Mr. Ford's idea to make shop superintendents, department heads and foremen out of them and he has arranged for a school at his Dearborn plant. They will be employed in the Mexican tractor plant which Mr. Ford proposes to build soon. He refuses to pay the bond required and has appealed to Washington.

King Company Fighting for Purchase Option

DETROIT, May 23—The King Motor Co. has filed suit against the Wadsworth Real Estate Co., Morgan & Wright, the United States Rubber Co., Central Trust Co. of New York, and James N. Wallace, trustee of New York, to enforce an option the King company claims it holds on the site of its proposed new factory.

Under a 10-year lease given by the Hupp Motor Car Corp., the King company occupies a plant, the lease of which contains an option permitting purchase at any time during the life of the lease for $27,500, plus the value of improvements. Buildings erected by the owners have been appraised at $65,925. A year ago the King company formally notified the owners of its desire to exercise the purchase option on May 1, 1919. On that date, and on the day previous, formal tender of the sum stated was made to the owners of the property, but they declined to accept the cash or execute a deed. The King company is now asking the court to enforce the option.

Foreign Agencies for Duplex

LANSING, May 23—The Duplex Truck Co. has established agencies in Barcelona, Spain, and Copenhagen, Denmark. The company now has 65 direct distributers covering every part of the United States.

Monthly production of Bessemer steel ingots, although showing a substantial advance during January and February, 1919, fell off considerably during March and April. Output of open-hearth steel shows a similar drop

AUTOMOBILE SHEET PRICES

(Based on No. 22 Gage. Other gages at usual differentials)

	Primes only per 100 lbs.	Primes when seconds up to 15 per cent are taken per 100 lbs.
Automobile body stock	$5.95	$5.85
Automobile body stock, deep stamping	6.20	6.10
Automobile body stock, extra deep stamping	6.45	6.35
Hood, flat, fender, door and apron, or splash guard stock	6.05	5.95
Crown fender, cowl and radiator casing, extra deep stamping	6.55	6.45
Crown fender, cowl and radiator casing, deep stamping	6.30	6.20

Automobile Sheet Extras for Extreme Widths:
- Nos. 17 and 18 over 36 in. to 44 in., 10c. per 100 lbs.
- Nos. 19 and 21 over 36 in. to 44 in., 30c. per 100 lbs.
- Nos. 22 to 24 over 26 in. to 40 in., 40c. per 100 lbs.
- Nos. 22 to 24 over 40 in. to 44 in., 80c. per 100 lbs.

Blank Sheet Extras to Apply to Narrow Widths:
- Oiling, 10c. per 100 lb.
- Patent leveling, 25c. per 100 lb.

Resquaring, 5 per cent of gage price after quality, finish and size extras have been added.

Seconds 10 per cent less than the invoice Pittsburgh price for corresponding primes.

CONVENTIONS

May 1-June 1—Atlantic City, N. J. Pan-American Aeronautic Convention and Exhibition—Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation.

June 2-3—Chicago, Ill. Natl. Gas Engine Assn. Hotel Sherman.

June 2-6—Hot Springs, Va. Convention Automotive Equipment Assn., Homestead Hotel.

June 3-6 — Washington. Pan-American Commercial Conference, Pan-American Building.

June 12-14—Pittsburgh. Annual convention of American Drop Forge Assn. and Drop Forge Supply Assn., William Penn Hotel.

June 23-28—Ottawa Beach. Mich. S. A. E. Mid-summer Meeting.

Sept. 22-24 — Philadelphia. Annual Convention, National Association of Purchasing Agents, Bellevue-Stratford.

May 12-15, 1920—San Francisco. Seventh National Foreign Trade Convention.

Foreign Trade Opportunities

WASHINGTON, May 24—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has received requests for automobiles or parts, airplanes, trucks and tractors and accessories agencies from individuals and companies in foreign countries. These are listed below. For further information address the Bureau of Foreign and Domestic Commerce and specify the foreign trade opportunity number.

Belgium—Medium priced cars and accessories. No. 29337.

Denmark—Medium priced cars, accessories and tractors in the Scandinavian and Balkan countries. No. 29342.

Spain—Cars, motorcycles and bicycles. Correspondence should be in Spanish. No. 29346.

American firm to represent manufacturers throughout Holland, Belgium and France in the sale of cars and accessories, etc. No. 29352.

American firm—representative to South America via Cuba—cars and accessories. No. 29365.

Mexico.—Tractors for Northern Mexico. Correspondence may be in English. No. 29390.

Spain.—Cars, bicycles, motorcycles and automobile accessories. No. 29400.

A National Trademark

WASHINGTON, May 24—A bill introduced in the House yesterday by Congressman Sims provides for a trademark to be selected by the Secretary of Commerce and which will be known as "The National Trademark." It is to be registered in the Patent Office in the name of the United States of America, without limitation of time and covering all classes of goods which are recognized under trademark laws.

The Secretary of Commerce is authorized to issue licenses for the use of the trademark under certain rules and regulations to any American manufacturer or producer. He is also given the right to institute and maintain proceedings when the rights of the trademark have been infringed upon.

The bill provides for the sum of $25,000 to be used in the expense of carrying the provisions of the act into effect, and has penalties for using any trademark similar enough to deceive purchasers into believing it to be the national trademark.

Change in British Import Restrictions

WASHINGTON, May 24—All restrictions have been removed on a number of commodities to Great Britain which may be shipped without individual licenses and which include: lubricators, injectors and ejectors, expansion joints, iron or brass pressed steel union couplings, copper, steel and iron wire rods, waste or scrap rubber.

Restrictions on the importation of motor car jacks have also been removed by Great Britain.

Farm tractors and tractor plows will be allowed only under special licenses and only in exceptional cases.

Lotex to Make Casings and Tubes

FOND DU LAC, WIS., May 24—The Lotex Tire Co. has been organized with an authorized capital of $100,000 to manufacture pneumatic casings and tubes. Work will begin in about a week on the erection of the first unit of its plant here to cost $35,000. The factory will employ 60 to 75 operatives at the start.

Goverment Places Orders for Parts

WASHINGTON, May 24—The Motors and Vehicles Division, War Department, has placed orders as follows:

B. F. Goodrich Rubber Co., Akron, 500 35x4½ fabric Q. D. clinchers, non-skid casings, and packing, $11,672.50.

Continental Motors Corp., Muskegon, Mich., miscellaneous spare parts for maintenance of 738 light aviation trucks, including boxing, $17,686.25.

Kelly-Springfield Motor Truck Co., Springfield, O., spare parts for 280 trucks, $14,223.26.

The Nash Motors Co., Kenosha, Wis., spare parts for trucks, $442,354.74.

Garford Motor Truck Co., Lima, O., four sets spare parts for repair and maintenance of 1½-ton trucks, $740,604.16.

International Motor Co., New York City, spare parts for maintenance of Mack 5½-ton trucks, $1,482,080.76.

Macomber & Whyte Open Branches

KENOSHA, WIS., May 23—The Macomber & Whyte Rope Co. has opened a branch at Birmingham, Ala., under the management of James A. Boope, southern manager, at 805 American Trust Bank Building. A New York City branch, with E. E. Robirds in charge, has been opened at 30 Church Street.

New York to Spend $16,000,000 on Roads

ALBANY, N. Y., May 23—The expenditure of over $16,000,000 is contemplated by New York state this year. The state is to receive from the Automobile Bureau in 1920 over $8,000,000 to be spent for maintenance and repair of highways as against $2,700,000 from the same source in 1918. In addition the various towns and counties will spend over $5,000,000 for the same purpose.

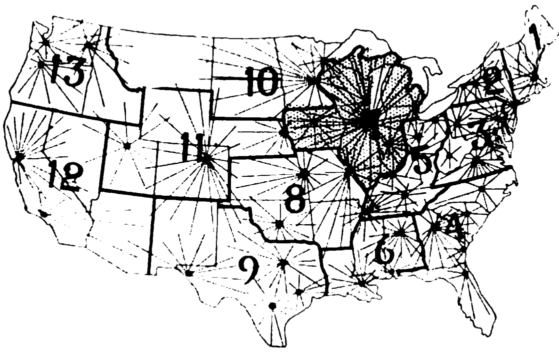
Link Advertising To Merchandising



This nation of 100,000,000 people cannot be handled efficiently from a sales standpoint until it is broken up into sections. Every large organization purporting to cover the entire United States finds branch houses, district managers, sales territories, etc., absolutely imperative. With population equal to half a dozen European kingdoms, and vast distances, it becomes elementary common sense to break the United States up into a number of logical merchandising units such as are shown on the map above.

This map pictures how each of these zones, and therefore the entire United States, can be covered by advertising in the forty-eight cities indicated, using newspapers with radiating circulation. The last four columns of the tabulation below prove that metropolitan newspapers cover the territory OUTSIDE the cities in which they are published even better than this territory is covered by any magazine.

Cultivate Each Jobbing Zone Intensively by Means of Metropolitan Newspapers

No jobber can sell the Chicago grocer but the Chicago jobber. No jobber can sell the San Francisco grocer but a San Francisco jobber. The grocers of Vinton, Iowa, are sold by jobbers from Chicago and from Iowa cities, but seldom by New York jobbers. The grocers of White Pigeon, Michigan, are sold by jobbers from Michigan and from Chicago, but never by jobbers from Philadelphia.

These are obvious merchandising axioms. One would think that his everyday knowledge of their truth would inspire every advertiser to adopt the corollary of localized advertising effort. Nevertheless, many advertisers seem to feel that general publicity thinly spread over a continent constitutes "national" advertising. As a matter of fact it is merely "geographical" advertising—advertising which covers the map of the United States but does not reach the people of the United States. The only true national advertising is that which moves the American people.

Note that the 78 Sunday newspapers listed below have a circulation in excess of 10,000,000 and a rate of .0015 per agate line per thousand. Twenty-one "general" or "standard" magazines have a combined circulation of 6,184,658 with considerable duplication and a rate per agate line per thousand four times that of the 78 Sunday newspapers.

Indianapolis Speedway Adopts the 3-Liter Limit for Future Races

Recent Contest Convinced Officials That 300 Cu. In. Cylinder Displacement Cars Had Developed Too Much Speed for Track — 183 Cu. In., New Maximum, Is Same as for French Grand Prix — Europe's New Cars a Disappointment — Mechanical Notes

INDIANAPOLIS, June 2—Next year's 500-mile classic in the speedway here will be confined to cars having a maximum cylinder displacement of 183 cu. in. This was announced, after Saturday's race, by Carl Fisher, the moving spirit behind the oval. Fisher said that he and his associates had become convinced that the 300 cu. in. cars have developed too much speed for the track, also that the track was too rough for 500 miles at the speed of the larger cars.

Fisher's idea is that, as the Indianapolis track is maintained for the purpose of developing motor cars, its best service to the industry will be the encouragement of smaller engines and lighter cars. His position is that there are many more cars being made with a smaller displacement than 300 cu. in. than there are above that figure.

The new limitation is the 3-liter limit adopted for the French Grand Prix and is the size to which all of the new European racing models will be built. With the support of the French rule, it is not anticipated that there will be any objection to this decision on the part of the Indianapolis officials. It will probably encourage European competition, but it will not lessen the advantage that will come to American racing and the American industry. It is worthy of note that Boillot's baby Peugeot is even smaller than the new limit, and this car ran well until it turned over within 20 miles of the finish, when it was in third place.

The victory of Howard Wilcox, driving a Speedway-owned Peugeot, was not a victory of speed so much as it was a victory of preparedness, thorough acquaintance with the track, and generalship, combined, as always, with good luck. The Peugeot is the same car with which the late Aitken campaigned so successfully. It has been worked over so much and so many parts of American manufacture incorporated, that it cannot now be called foreign. Wilcox has it in such shape that he went through the race without having to make adjustments. His three short halts at the pits were for tires and supplies. He did not drive exceptionally hard; made no exceptionally fast laps. He won because others, who drove faster while on the track, could not keep going.

The race this year did not make a record for the distance. Wilcox's time was more than 10 minutes longer than DePalma's record for the 500 miles in 1915. Saturday's average speed was 87.12 m.p.h., 2.72 m.p.h. less than the 1915 records.

If DePalma or Gaston Chevrolet, who between them led the field for the first half of the race, could have kept on the track, the record for the distance would have been broken. DePalma led the field for the first 150 miles at an average of better than 92 m.p.h. His stop threw Chevrolet in the lead and the speed dropped to 90 m.p.h. The Italian gained the lead again and pushed the pace up to 91.6 m.p.h., until valves and wheel bearings checked him. His speed of 92.20 at the 100-mile mark is a track record for that distance.

Wilcox led almost the entire last half of the race, taking the pace when the Packard was held at the pits for repairs. The Peugeot, which the winner drove, was well up among the leaders most of the way. It was in third place at 25 miles and second at 50. Then Wilcox fell out of the money for nearly 50 miles, but, climbing steadily, at 125 miles he was back in third place and crowding DePalma and Gaston Chevrolet. He took second place when the Frontenac hung up at the pits at 200 miles and was in

position to take advantage of DePalma's difficulty at the halfway mark. This put Wilcox in first place with only a slight lead over Cooper. The menace of the Stutz ceased, however, when the Californian stuck a valve, but continued, slowly dropping behind while the engine thumped a wail of protest that could be heard half around the track.

By the time the race was within 60 miles of the finish, the field had divided itself into two sections. With Wilcox leading Hearne by 5 miles, and 14 miles ahead of Goux for third, Alley, Guyot and Louis Chevrolet, at the wheel of Gaston's car, were fighting for position. This bunch of six cars was 40 miles ahead of the rest of the field, with Vail's Hudson and Boillot's Baby Peugeot fighting for the doubtful honor of leading the second contingent.

Hearne Finishes Second

Hearne, by heady driving, brought his Durant Special into second money and finished less than 2 minutes behind the leader. He made only two stops and these for supplies. Like Wilcox, Hearne scored by steady, consistent driving. There never was a time during the race when he was not in the money and he climbed till, when the race was half over, he was in second place and only 10 miles behind the leader. This was the status till Willcox stopped to prepare for the final dash, which gave Hearne a chance to pick up two laps.

The Durant Special which Hearne drove was entered by Clifford Durant, son of W. C. Durant, one of the big men of the industry. The car is the Stutz that Gil Anderson drove.

Two Out of Four Ballots Finished

Another Speedway-owned Peugeot captured third place under the piloting of Jules Goux, winner of the 1913 sweepstakes. Goux did not show among the contenders until the race was about half over, but at 350 miles he had climbed into fourth place, jumping to third with 50 miles to go when the Frontenac got into difficulties. Goux made only 5 stops, all of short duration.

Of the four Ballots started, only two finished, but both in the money. Guyot captured fourth place, and Rene Thomas, winner of the 1914 race, nosed into the purse for tenth place. The other two came to grief. Bablot's machine, with Chassagne, the former Sunbeam pilot, at the wheel, turned over. Louis Wagner's machine broke a wheel early in the day.

The Ballot cars, built especially for this race at an expense of $120,000, and brought over from France with a

crew of Europe's best drivers, did not come up to expectations. That they had speed was shown in practice and in the elimination trials. They did not stand the 500 miles on the bricks. Guyot only made three stops, and these not of long duration. Thomas made five stops for supplies and tires. He seemed to be taking things very easy.

Joe Boyer, in his Frontenac, threw a left rear wheel and broke the axle. The accident occurred near the pits and the car coasted in on the hub of the broken wheel.

This accident resulted in a serious tie-up of the whole race.

Toft Seriously Injured

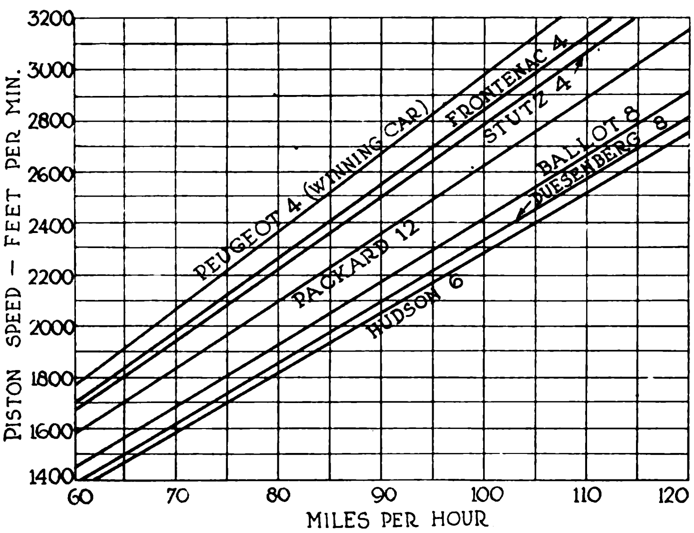
The car crossing the timing wire with its broken wheel cut the timing wire. Omar Toft in his Toft Special was following Boyer. The wire released from the tension of the springs curled up in the air and struck Toft, cutting him severely in the throat and opening the jugular vein. Toft was bleeding profusely, but continued to drive his car. He was forced to stop for medical attention, though, in the thirtieth lap. Inspection showed that he was injured rather severely and therefore did not continue the race.

The breaking of the timing wire also caused some commotion in the timing stand. A new wire was hastily substituted and the click of the chronometer continued.

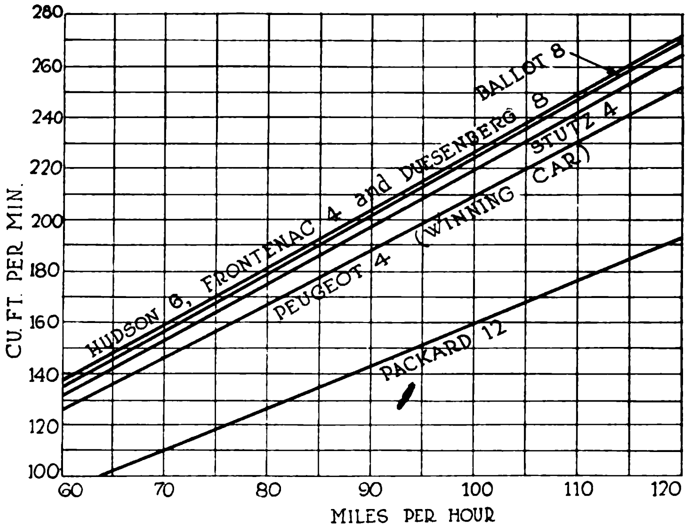
The real race was between Louis Chevrolet and DePalma for sixth and seventh places. Lap after lap they fought, DePalma coming up from the ruck after changing a wheel bearing and Chevrolet fighting to make up the time lost in changing a steering knuckle. The battle brought the grandstand folk to their feet time after time, this after the race had been won. So close was the finish that only a re-check of the timing tape could determine who got in first. In the re-check DePalma, who had been given sixth, unofficially, had to take seventh in favor of Chevrolet.

The Frontenacs seemed too lightly constructed for the track. Boyer lost a wheel and Louis Chevrolet lost two by the aluminum drum failing. The latter also broke a steering knuckle and Mulford broke an axle driveshaft.

It was estimated by Speedway officials that there were over 100,000 present. In addition there were a great number of machines in the center of the oval and around the inside of the ring. The roads leading to the course were heavily congested with traffic an hour after the race had started.



Piston speeds in feet per minute of some of the cars in the race



Cubic feet of gas displaced per minute at different speeds by some of the cars

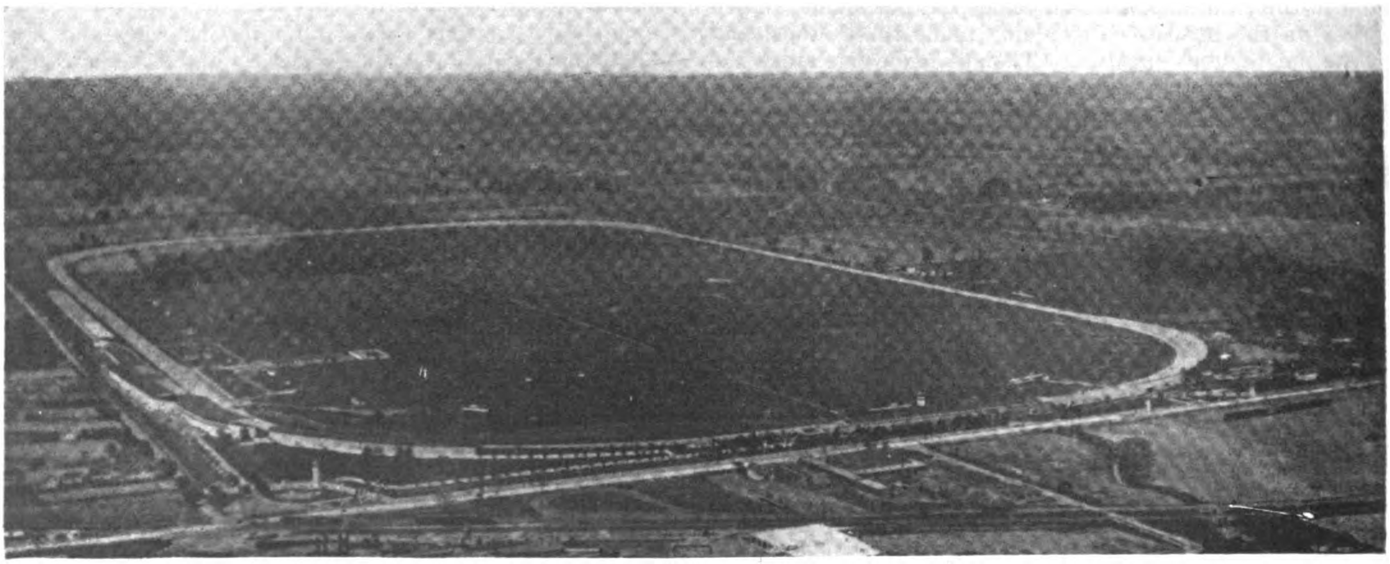
Mechanical Notes from the Race

One of the best reasons for racing is that it enables us to determine the weakest links in the chain of car components and by this knowledge to profit in the design and construction of vehicles intended for passenger or commercial purposes. The mortality among racing cars is always so high under the severe stresses which they are compelled to stand that the conclusion of a race brings to light a total list of minor and major troubles which often indicate to the designer what it is permissible to do in ordinary construction.

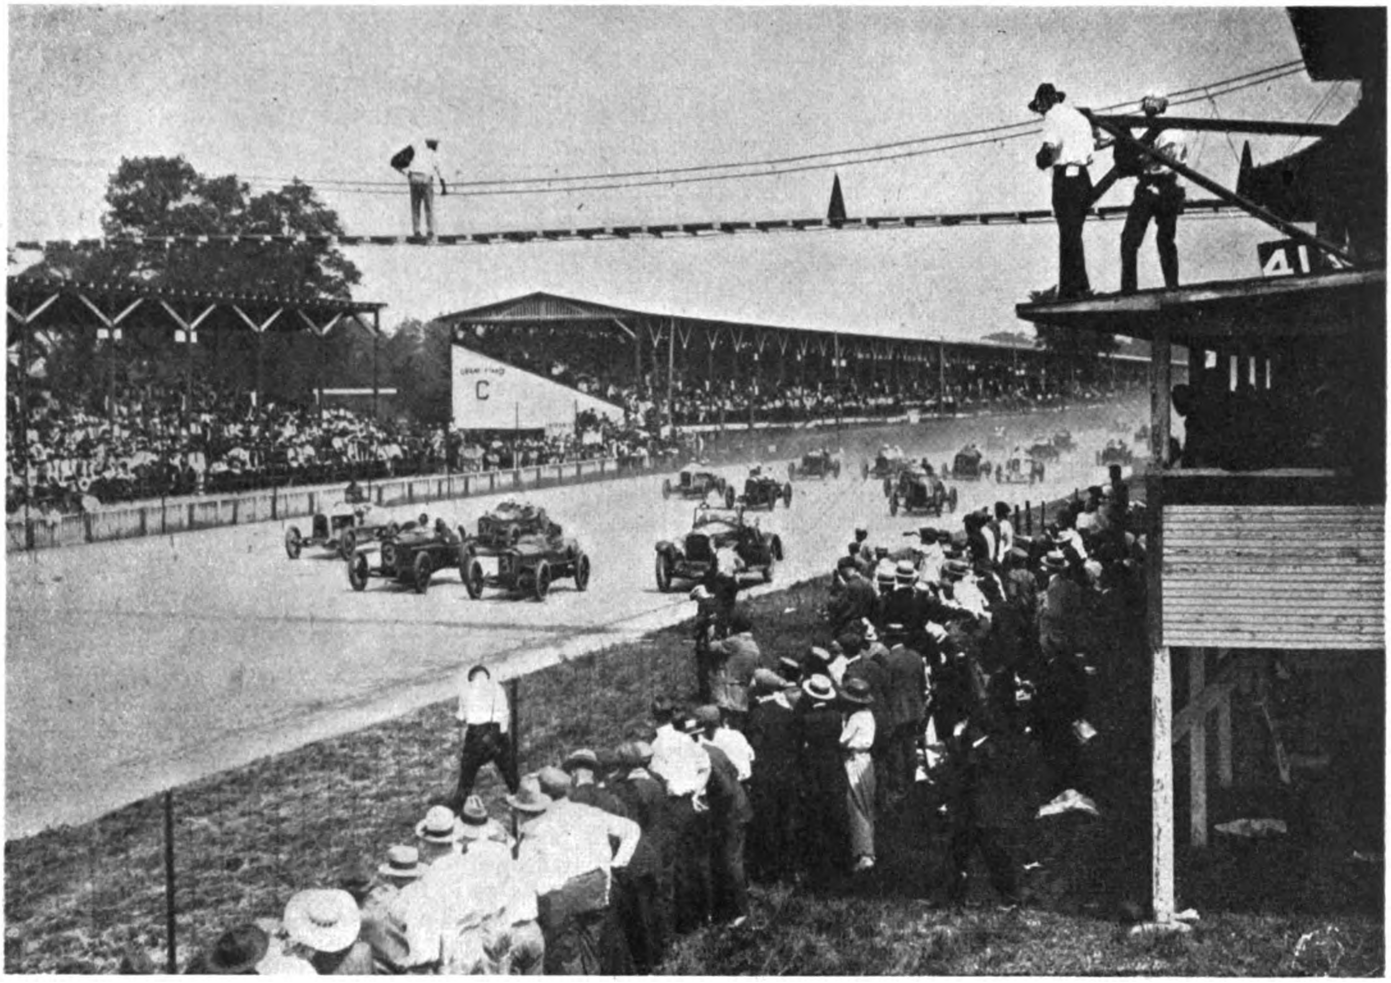
Furthermore, from a theoretical standpoint there is much to be learned in regard to what can be done in the handling of gases at high velocity and what is the limit in allowable piston speeds. Little or no problems of carburetion are, as a rule, apparent, but there is always much to learn in manifold design and, particularly, weak spots in the cooling system are brought to light by the failure of spark plugs and often through the tendency to overheat, as indicated by excessive steaming, etc.

The major number of stops at the pits was directly due to tire failure. This would be expected, as the race was run under a burning sun on a track which was already superheated by two days of exceedingly hot weather which preceded the start of the classic. Sixty-seven tire changes were made. Of this number thirty-one, or nearly 50 per cent, were right rears, which is the usual percentage for the Indianapolis track. Fifteen were left rears, twelve left fronts, and nine right fronts. It would be wrong to assume from these figures that tire performance has not improved. In the first place, probably 30 per cent of the tires were changed before it became necessary, because the cars were drawn up to the pits for other purposes, affording the opportunity to make the replacement. Secondly, the conditions as far as heat and direct sunlight were concerned were never equaled at an Indianapolis race. During practically the entire period the track was in the direct glare of the sun, with no sheltering clouds in sight.

Three cars changed tires six times, these being De Palma's Packard, the Hudson Special driven by Haibe, and the Ballot driven by Guyot. Three cars changed five times; two changed four times; three changed three times and the remainder changed at least once. No car went for the entire distance without a change.



Airplane view of the speedway



As usual, the start was a flying one, J. G. Vincent and Eddie Rickenbacker pacing the pack for a lap and then drawing to one side. This is the end of the paced lap

The winner made only one stop, at which time he took on a complete set of tires as well as oil, gas and water, and he also tightened his shock absorbers. Disregarding this stop, it was the steady running program of Wilcox which won. De Palma and Louis Chevrolet, who proved in the early part of the race that they were the most dangerous contenders as far as actual speed was concerned, had to make stops for failure in vital parts. De Palma had to make adjustments on his valve drive mechanism during his first stop, and on his second stop had to replace an entire front right wheel bearing assembly. This took such a long time that it put him out of the running so far as first place was concerned. While the car was on the track, however, its steady, fast running made it the pace maker, and had it not been for these two mechanical mishaps, De Palma probably would have been the winner. At the 100-mile and 200-mile marks he was in the lead, having broken the speedway record for these distances.

The failure of the Frontenacs showed that they were too lightly built to withstand the stresses imposed by the Indianapolis track. In fact, dangerous weakness was apparent on the rear axle drums. Before the race, on the brake test, the drum on Louis Chevrolet's car cracked under the strain imposed by bringing the car to a stop. This break became apparent immediately the brake was applied. It was on the left rear drum carrier. The right rear drum on the same car broke during the race.

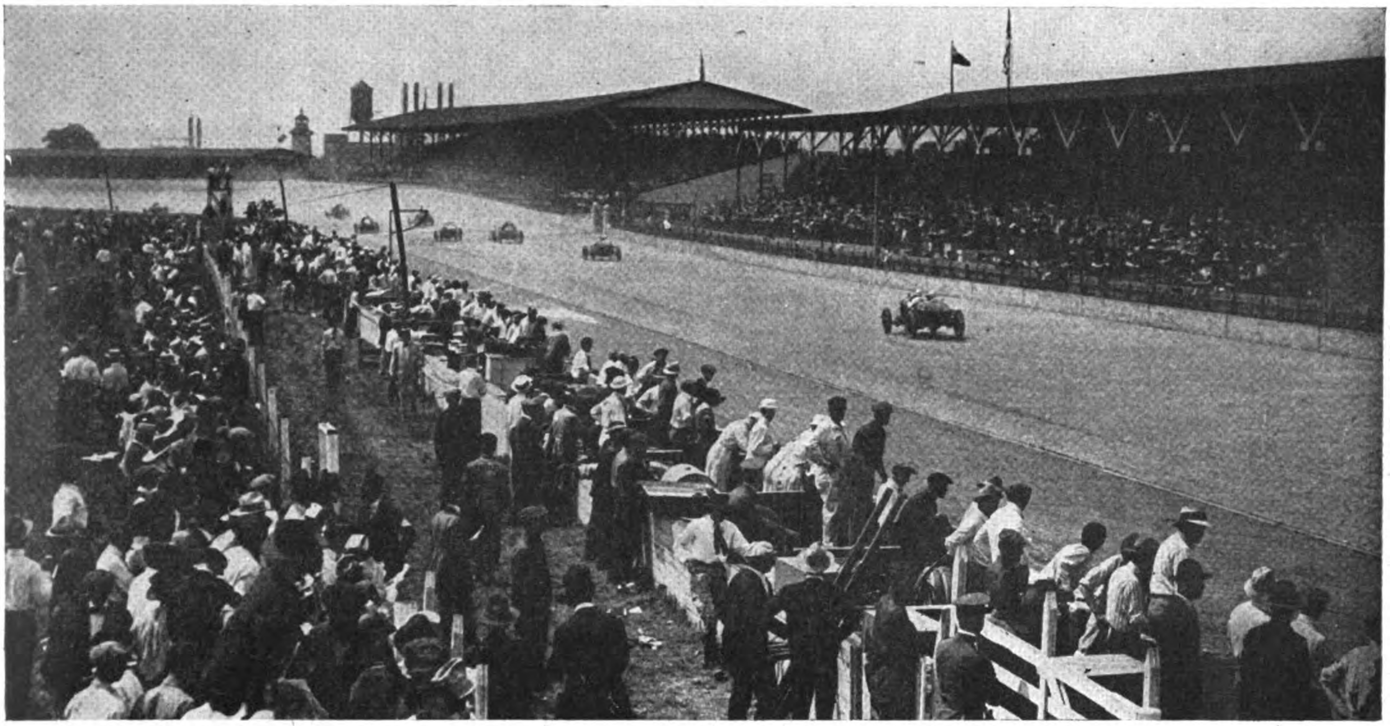
The front axle was also too light, at least the steering knuckle spindle. This became crystallized, due to the continuous bouncing over the rough track, and when the car was on the turn entering the home stretch it broke off, throwing the wheel over the fence, and it was only by the most skillful driving that Chevrolet was able to bring the Frontenac to a halt before his pit on three wheels.

Twice during the race this three-wheel performance was necessitated by failures of the front and rear axles on these cars. The rear axle failures were evidently due to the fact that the aluminum employed was not strong enough to endure the torsional strains resulting from the tremendous acceleration upon leaving the curves.

The Indianapolis track is banked for 90 m.p.h., which makes it distinctly a drivers' track and allows the human element to enter in the management of a car on the turns to a far greater extent than on the 120 m.p.h. New York Speedway. For this reason spark plug troubles are always more apparent on this track, due to the fact that it is necessary to shut off on the turns, allowing the oiling systems a chance to load up before the throttle is again opened. Puffs of smoke are always apparent at the entrances to the back and home stretches, due to the use of the accelerator in gaining speed for the straightaways. It is not surprising that there were twelve stops for spark plugs, during some of which the whole set of plugs was renewed.

The Ballot cars proved a disappointment. While steady, they either did not possess the necessary speed to bring them into prominent position, or else the drivers did not take the same chances on the curves as the others.

The Sunbeams were withdrawn just before the race, and a rumor went around that this was due to the fact



Cars bunched at the southeast turn

that their cylinder displacement was 304 cu. in. and thus beyond the set limit. Investigation has about disproved this, and it is now stated that Resta, in a test drive, found that at 2500 r.p.m. of the engine there was a critical speed at which vibration was so severe that it would have been impossible for the cars to withstand a 500-mile grind. The cars are to be shipped back to England.

There is no doubt that the rough track greatly bothered the Ballot drivers. These cars may show higher speeds in future events than they did at Indianapolis, as there was a feeling before and during the race that they were being held back.

Engineering opinion is growing that 300 cu. in. is too high a limit for cars for the Indianapolis track: it is felt that the limit should be materially reduced in order that racing may be of the greatest possible benefit to the designer. Under present conditions, the cars are so much faster than the drivers (to use a track expression), particularly on tracks like the Indianapolis, that most of the value of the race is lost.

The Duesenberg 4-cylinder, 16-valve engine of 3¾-in. bore by 6¾-in. stroke, was used by O'Donnell (Duesenberg), Hitke (Roamer Special) LeCocq (Roamer Special), Thurman (Thurman Special), and D'Alene (Duesenberg-Shannon Special). These cars showed sufficient speed to put them well up in the race, but owing to the inexperience of their drivers, two of the cars were involved in fatal accidents.

A careful study of the race makes it very apparent that practically all of the cars were much faster than the drivers, which is to say that the cars were capable of developing a speed beyond the limit at which their drivers could safely handle them. This is particularly

All cars carried Goodyear tires. All cars carried Hartford shock absorbers. All cars carried Rudge-Whitworth wheels.

Valve Sizes of Some of the Cars

Car No.	Car	Diameter Exhaust Valve, In.	Diameter Intake Valve, In.	Lift Exhaust, In.	Lift Intake, In.
6	Peugeot (Goux)	2	1	1/2	1/2
37	Peugeot (Boillot)	1 3/8	1 [illegible]/16	[illegible]/16	[illegible]/16
46	Premier	1 [illegible]	1 [illegible]	3/8	[illegible]
47	Premier	1 [illegible]	1 [illegible]	3/8	[illegible]
45	Peugeot (Wilcox)	1 [illegible]	1 [illegible]	3/8	[illegible]
15	Roamer (Le Cocq)	2 3/8	2 3/8	3/8	3/8

Most drivers are very secretive about valve sizes. Those given in the table are known to be accurate.

true in those cases where the drivers had had little or no experience in track racing. The Ballot cars may show up better in races on speedways which are banked for a speed of 120 m.p.h. The drivers on the Ballot cars were also too much exposed to the wind pressure. This should be corrected and the seating arrangement should be so changed that the drivers may occupy a more lax position than was possible in the Indianapolis race, where they were notably tense and not at all at ease.

Car Characteristics

Widely differing characteristics were possessed by the cars entering the race. An analysis shows that the winning Peugeot had the highest piston speed of any of the cars. At 87.9 m.p.h., the average speed maintained by the Peugeot in winning the race, the piston speed was 2620 ft. per min., or about 600 ft. per min. more than that of the Hudson, which had about the lowest piston speed of any of the cars in the race. The accompanying chart gives graphically the piston speeds of the typical cars in the race and it will be noticed that the winning Peugeot was considerably faster as regards piston velocity for a given car speed than the other cars.

Considering gas velocities, in the absence of complete statistics on valve areas, these may be plotted on a basis of cubic inches of gas displaced at definite speeds. It is interesting to note that outside of the twelve-cylinder Packard, the winning Peugeot had a lower displacement per minute at any given speed than the other types. This is in spite of the fact that its piston velocity was the highest and is due to the dimensions of the Peugeots, which have a piston displacement of 287 cu. in., as compared with the others, which are close to the 300 mark. The only small displacement car in the race was 150 cu. in., this being the Baby Peugeot with a 2.15 15/16 x 5½ in. engine.

The 12-Cylinder Packard

The Packard 12-cylinder car, which, from its performance on the first 100 miles of the race, was probably as fast as any car on the track, if not the fastest, has only a 4½ in. stroke. Thus, although turning at sufficient speed to give it an intermediate position as far as piston speed is concerned, its position is low on a gas volume basis, and the car probably would show up notably from an economy standpoint were it possible to secure accurate records. Unfortunately, this is not the case, owing to the impossibility of measuring the fuel remaining in the tanks at the conclusion of the race or of measuring the amount put in during the race because of the quantity spilled.

From close observations it appears that the 500 miles were run by the winner on 45 gal. of gasoline. This would give an average of approximately 11 miles to the gallon, showing a high thermal efficiency, as would be expected under conditions of practically wide-open throttle at high speed.

The spark plug troubles were due to fouling more than to fusing, as only little of the latter was seen. The fouling trouble is no doubt the result of the oil-loading due to the acceleration on the turns, as previously pointed out. The only car which showed symptoms of plug fusing due to overheating was car 19, Hudson Special. This car had to change plugs four times and took on water six times, showing that it was badly troubled with overheating. On this same car a sticking valve gave a great amount of trouble.

In studying the reasons which eliminated the different cars, the fact becomes apparent that more failures were due to drivers not experienced on the Indianapolis track than to any imperfection in the cars themselves, although such defects showed up in some instances. The list of eliminations is as follows:

Car No.	Lap		Cause
5	11	Frontenac	Burned out rod bearing
39	30	Premier	Broken hub
28	9	Baby Peugeot	Broken rocker arm
2	37	Durant Special	Broken driveshaft
9	49	Richards Special	Burned out rod bearing
34	45	Ballot	Broken right rear wheel
12	57	Duesenberg	Burned out bearing
18	44	Hudson Special	Turned over on back stretch
10	66	Stutz	Broken piston pin
33	63	Ballot	Ran into wall on back stretch
29	71	Mesaba Special	Burned out connecting rod bearing
1	55	Durant Special	Broken steering connection
43	45	Thurman Special	Trouble unknown
36	37	Ogren Special	Broken oil line
19	70	Hudson Special	Broken oil line
15	96	Roamer	Burned up
22	119	Hudson Special	Broken steering gear
37	191	McCoy Special	Turned over on back stretch

While it is almost impossible to tell the cause of accidents such as those which marred Saturday's race, it is certain that in practically every case the lack of experience was one of the main factors.

Minor Troubles Cause Delays

As in all long-distance races, minor troubles were responsible for a great many delays. For instance, one of the Peugeots had to come into the pit twelve times owing to oiling troubles. This car could not hold its pressure and had to draw up to the pit to have the oil pump manipulated at frequent intervals. Trouble of this kind can, of course, be readily avoided if it is foreseen. The same ap-

Wilcox, the winner receiving congratulations

Co-operation Profitable to Employer and Worker

IT IS not always easy to see the practical application of plans dealing with the question of human relations and containing departures from the general practice.

The questions asked by manufacturers to-day indicate the desire to see results. If the human side of industry had been studied with the care given to the more mechanical elements of production, those questions would not arise so insistently. Under the circumstances, it is fortunate that there are a number of cases in practice which can be reported upon from the results obtained, and the account printed here tells of the benefits to one manufacturer after two years' experience with such a plan.

By Harry Tipper

IN previous articles AUTOMOTIVE INDUSTRIES has explained in more or less detail the organization and form of "employes' representation" plans as adopted by several important American industrial establishments. It will be of interest now to study the results of some of these experiments and to find out just how they work out in actual practice.

A good example of an "employes' representation" plan or "Industrial Democracy," as it is called, is that in operation for the past two years at the tobacco pipe manufacturing plant of Wm. Delmuth & Co., at Richmond Hill, Long Island, N. Y., where 900 men and women are employed.

Leopold Delmuth, president of the company, who considers the experiment a success, says that the plan is "based upon the confidence and co-operation of the whole body of workers." According to Mr. Delmuth, "one of the best features of the plan is that it has succeeded in establishing a happy relationship between employer and employes. It has also helped to produce more and still better pipes."

Profit Sharing an Incentive

Not only does the plan bring about co-operation between the employer and employes in the conduct of the works, but it also provides a means for giving the workers a share of the profits, as the savings obtained under the plan through increased output or reduction in overhead are divided between the company and the employes on a 50-50 basis. The profit-sharing is made effective every two weeks, the employes receiving separate pay envelopes marked "Employe's Dividend." In two years this bi-weekly dividend has never been less than 6½ per cent the wage and it has been as high as 17½ per cent.

Regarding this method of profit-sharing, Mr. Delmuth says: "We believe that profit-sharing is one method, and ours, based upon actual performance of the worker, is another. The profit-sharing plan has many worthy features, but we do not believe that many workmen understand the inevitable variation of the percentage of profit. Furthermore, we do not believe that he should be made to suffer for any losses connected with sales, finances or raw merchandise investments, all of which are beyond his control. Our plan is based upon a saving accomplished by the worker in both production as well as overhead.

"Furthermore, under our plan whereby we give our employe his dividend every two weeks, incidentally in a separate envelope marked "employe's dividend," he does not have to wait for what seems to him the indefinite future to learn whether or not the employer is living up to his promises. He can watch his dividend grow larger or smaller, and soon he will begin to learn that when every machine is running all the time he makes more money than when his fellow workers take holidays and machines are left idle. Thus he comes to know that co-operation means a larger pay envelope."

What's in a Name?

It makes little difference as to what name a plant organization of this kind is given, whether "Employe's Representation" plan, the name applied at the plants of the Colorado Fuel & Iron Co. and the Midvale Steel & Ordnance Co., or "Industrial Relationship" plan, as it is named by the Standard Oil Co., or "Industrial Democracy," the name adopted by the Delmuth Co.

In England the much-talked-of "Whitley Councils" plan of "Works Committees" is of a similar character, except that it goes further and provides for District and National Joint Councils of employers and employes. In America co-operative methods of this kind have been applied only to individual industrial enterprises.

In the Delmuth plant the originators have chosen to give the plan character by calling the representatives, or council, chosen by the employes the "House of Representatives." Carrying the governmental idea of or-

ganization further, they call the council of foremen and heads of departments the "Senate," and they call the sessions of company executives the "Cabinet."

In several of the "employe's representation" plans adopted by other industrial enterprises in this country machinery is provided by means of which differences between the employers and employes can be carried up from the body directly representing the employes to higher and still higher authorities, and finally, if necessary, settled by some form of arbitration.

In the plan used at the Demuth works no provision appears to have been made for arbitration of differences. In fact, if the employes take action contrary to the opinion of the company executives, means are provided by which such action can be "vetoed" by the "Cabinet" or company officials. It is stated, however, that during the past two years the "Cabinet" has never had occasion to exercise this power.

The first question that naturally arises is, "Why did Demuth & Co. feel that it was wise or necessary to inaugurate such a plan in their works?"

Mr. Demuth denies emphatically that the scheme was inaugurated because of labor trouble, or for fear of any. He says they went ahead with it simply because they considered it a wise and liberal, "as well as a paying policy." As he puts it: "When the growth of our business made intimate relationship between the employer and employe impossible, we realized that only through giving the worker his say in the running of the plant could we get the co-operation so urgently needed to further promote business. Hitherto, the labor leader has been the only teacher of the working man, and we knew it would pay us to endeavor to educate the worker in a way that would teach him the value of co-operation."

Effect on Production

As to whether the plan turned out, as was hoped, to be a "paying" investment, Mr. Demuth is equally emphatic in his affirmative, though he says the profit of the plan to the company was indirect, defining his opinion as to the results as follows: "We did not, in the beginning, have any illusion that Industrial Democracy would keep our costs down to pre-war basis. How much lower they have been under Industrial Democracy than they would have been without this plan is largely a matter of speculation. We honestly feel that we have benefited distinctly from this point of view. We are convinced that under the old system we would have had a much more rapidly rising scale of wages, and would have had the difficulties with employes suffered by many other firms, all of which would have increased costs far beyond the point to which they did rise.

"Many of our men are piece workers. Some were in the habit of rushing their work so that they could make the most money regardless of the quality of their output. At the meetings of the Lower House, the representatives of the workers learned that this policy was lowering their dividends, for it was resulting in a large amount of waste. The representatives brought home this fact to the workers, who began to realize that any gain made by rushing their work was more than offset by the loss in dividends caused by this method. Consequently, they soon began to turn out better pipes.

"Another important factor in raising the standard of quality is that, by reason of his having a voice in the management of the plant, the worker takes more pride in his product, as in the case of the craftsmen of old."

Another good effect that the plan has had upon the business of Demuth & Co. has been in the reduction of the turnover. This has gone down to so low a point at this plant that it is no longer a serious factor. During the height of the war, when the high wages of the munitions plants were tempting all workers, and other manufacturers were feeling the shortage of labor, the mutual interests created by the Industrial Democracy plan at the Demuth works kept the men at their jobs. Knowing that lack of help would reduce their dividends, the employes saw to it that their fellow workers stayed.

Before the plan became operative, the employes worked fifty-three hours a week. At one of their "House of Representatives" meetings they voted to reduce the working time to fifty hours. The "Cabinet" did not veto the change, and it became effective. A trial of the new time schedule showed that instead of a decrease in output, the production had been increased 8 per cent.

This change worked out so well that another reduction was made in the working week to forty-eight hours. The company officials admit that this reduction of working time has not decreased production.

How the Workers Like It

At the start many of the employes looked upon the plan with suspicion and doubt, but all now seem to favor it. As one workman reviews it:

"I have seen Industrial Democracy in operation at this factory for the past two years, and the main reason I am for it heart and soul, is because I know that, through it, I can always get a square deal.

"When a man in my department has a grievance, he comes to me and tells me about it, and he knows that I will take the question up at the next meeting of the 'House of Representatives,' and, consequently, the foremen in the 'Senate' and the 'bosses' in the 'Cabinet' will know about it. They will act on it one way or another, and my experience has been that every question has been settled fairly.

"Nowadays at the plant you never hear a foreman urging the men to get on the job. There is no need for it. We all know that by doing our best all the time we are increasing our own dividends. Now whenever a man 'knocks off' early, comes in late or takes a holiday, it is not the boss who wants to know the reason, but the other men and women workers whose dividends he is lowering Before Industrial Democracy was put into effect, it was every man for himself; now it is all for one and one for all.

Things Are Different Now

"Years ago, if a worker had a grudge against the foreman he would probably lay down on the job whenever he thought he wasn't being watched; but that is a thing of the past, for whatever complaints a man has are now quickly settled in a way satisfactory to everybody.

"And another thing, Industrial Democracy has proven that some of our men had, stored up in their minds, ideas for new machinery and other labor-saving devices; but they kept these plans to themselves because they were not sure how they would be received by the management. Now, a man with a good idea knows that not only will his suggestion be welcomed, but that if practicable it will be rewarded. In our plant to-day, labor and time-saving machinery, invented by the men, is lowering the cost, increasing production, and thus earning dividends.

"Industrial Democracy has given us 'a say' in the management of the shop; it has reduced our working hours from 53 to 48 a week; it has given us insurance; it has given us a lunch room where we can get good meals for 20 cents; it has made this shop a better place to work in; it is teaching English to our foreigners and helping them to become Americans; it has taught us that the firm has troubles and worries just the same as we have, and that by working together we all benefit."

German Destruction of the Belgian Automotive Industry

Only One Factory Escaped the Complete Blight, Due to the Use of Plant As Machine Shop—Its Present Capacity Is One Car Daily—Country Likely to Prove New Field for Trucks and Tractors

By W. F. Bradley

THE Minerva automobile factory at Antwerp has as its managing director Mr. S. Dejong, who is of Dutch nationality. It might have been thought that this would have had a restraining influence on the German authorities. Mr. Dejong was under no delusions. He fled to Holland the day the German army entered Antwerp and was not long in receiving an official communication in the name of the German Emperor ordering him to return and take control of the factory.

Taking possession of the Minerva factory in October, 1914, the German forces immediately began to strip it. When the armistice went into effect they had removed 750 machine tools, all the automobiles and stocks of raw material to the value of $1,200,000, on pre-war estimates. Removals were continued until the last moment. On Nov. 11, 1918, boxes were standing in the street labelled for shipment into Germany. The electric transformers were not taken away, for these were required to furnish current for lighting the buildings. They had been numbered and catalogued, however, in view of a requisition. During the last 6 months they were in possession the Germans exacted 1 ton of brass or bronze goods per week. This was the work of the R. O. H. M. A. (Rettung, Ordnung und Hilfe, Militarische Abteilung).

When the Germans departed, there was not a single machine tool in the whole of the Minerva factory. But the buildings were stacked with wrecked German automobiles and automobile trucks, and the refuse of war was to be found everywhere, even on the flat roofs. Two hundred beds had been placed in the factory buildings. There was unmistakable evidence that these had not been used exclusively by soldiers. The filth was indescribable.

When I visited the Minerva factory I was shown a most complete selection of drills, taps and dies, reamers, jigs, etc. The question naturally was asked why this valuable material had been left behind when everything else had been taken away or destroyed.

From the beginning of the war to the middle of October, 1914, when Antwerp fell into the hands of the German army, the Minerva factory had been producing war material. The directors realized two weeks in advance that the city would fall, and in the belief that the war could not last more than 6 months they had all their small tools, jigs, dies, etc., wrapped in oiled paper and hidden in the factory chimney. For 4 years German soldiers leaned against the chimney, within which this valuable material was hidden.

One day they suggested that a fire should be made in this particular chimney. One of the staff remaining at the factory informed them that there had been an accident at an earlier date, and suggested that the fire should be made elsewhere and the pipe brought into the chimney above the obstruction. His advice was taken, and more than 4 years later, when the enemy retreated, this material was found practically intact.

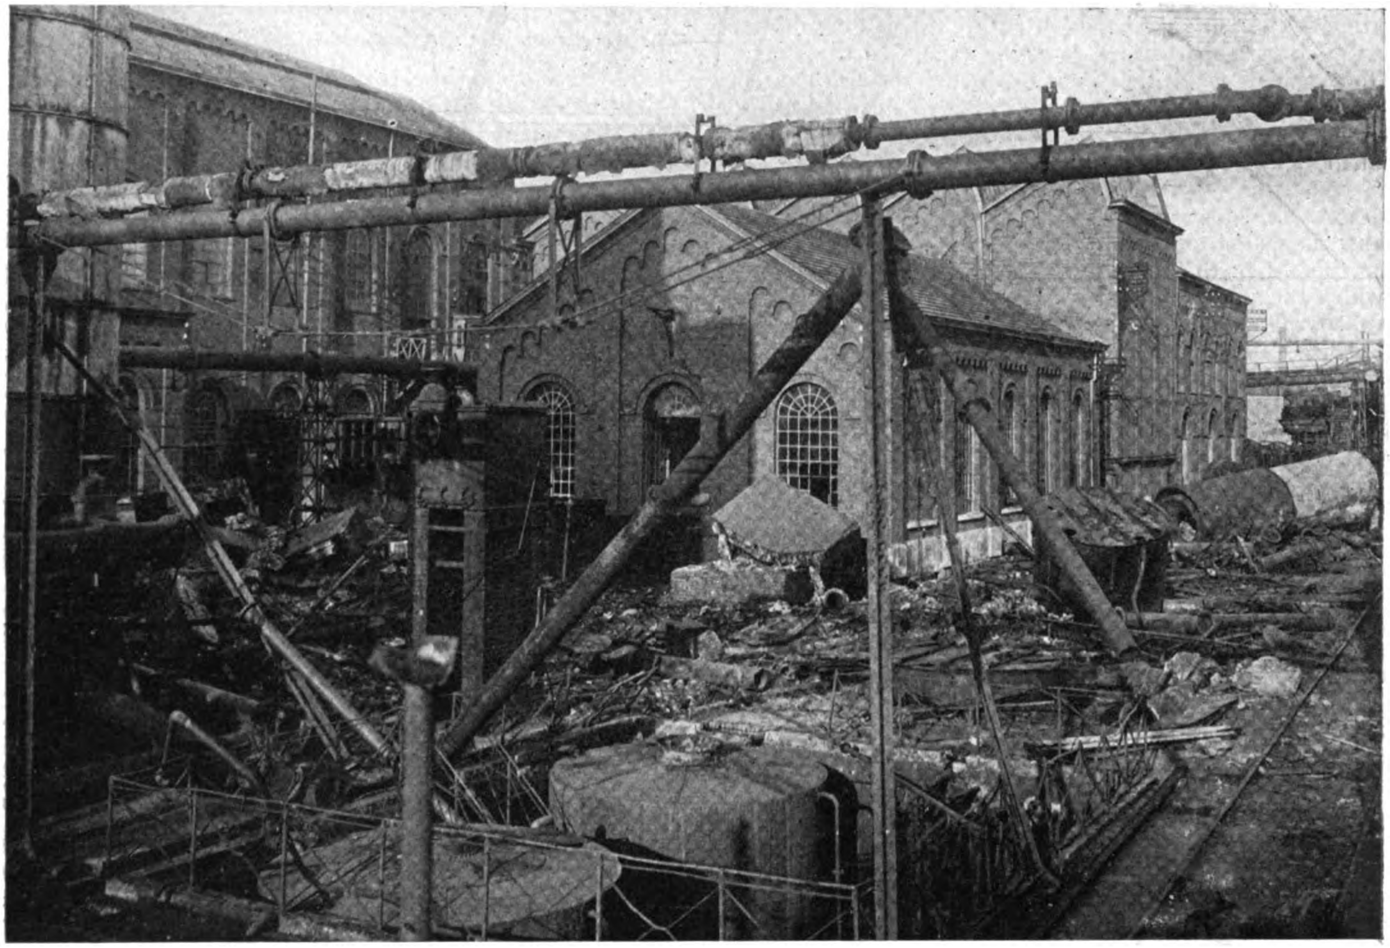
Soon after seeking refuge in Holland, Mr. Dejong began to get machinery together to be used when the war was over. With Belgian refugees he began the construction of 150 lathes. This work was proceeding very satisfactorily, when the German authorities were informed of it and placed Mr. Dejong on the blacklist. The consequence was that no raw material could be obtained, for Germany had practically complete control of this, and that all the Belgian refugees were thrown out of work. Although the lathes could not be finished, work was found for the men by the Dutch Government.

Fortunately American lathes and other machinery were found on the Dutch market, and were purchased in anticipation of a resumption of business. The managing director of

THIS is the second of a series of articles by W. F. Bradley, special European correspondent of AUTOMOTIVE INDUSTRIES, on the destruction of the automotive industry in Belgium. Last week the general situation was graphically described. In this article Mr. Bradley tells of the conditions he found at the various factories. In the big fact that production ability was destroyed in all but one factory the situation is common. But in each factory a different degree of barbarity was practised. Mr. Bradley went to Belgium to investigate the automotive industry for this publication and as its representative he was accorded many special privileges by government officials and leaders in the industry.

—EDITOR.

The Exteriors of Two Factories Are Typical of Scores



The Cockerill steel works when the Germans left. The avowed object of this wrecking was to obtain metal to be used as raw material

Shop fittings were ripped out and thrown into the yard. The Germans had no use for wood partitions so left them outside the Derihon factory

the Minerva company was also able to visit America and arrange for the purchase of machinery, to be delivered when the war was over. In consequence of this, the Minerva factory, although stripped bare by the enemy, probably will be in production before the end of the year. At present, repair work is being done for the Belgian Government, while the shops are being cleaned, shafting erected, and machinery laid down.

The treatment accorded to the Nagant company at Liége is an example of rapidity. Before the end of 1914 much of the machinery had been seized. Even at that date a complete organization existed for receiving and disposing of machinery seized in the countries which the Germans had invaded. This business was handled by the E. Sonnenthal company of Berlin. The receipts stated that this machinery was taken on a loan and would be returned later with an allowance of 10 per cent depreciation if kept for more than 6 months and 5 per cent if kept less than 6 months. The Germans fixed the value of the machinery they seized, but the Nagant brothers refused to recognize this price.

Type of receipt given by the German authorities for requisitioned machinery

In early 1915 an engineer arrived at the Nagant factory with a story that he was entrusted with the task, on behalf of the German Government, of protecting the Belgian industry. He suggested that the factory should be turned to work for Germany on non-war materials. The Nagant brothers refused. It was pointed out to them that they were risking deportation to Germany. They replied that they would risk death rather than work for the enemy.

"I shall be obliged, then, to take entire possession of your factory," replied the delegate of the Imperial Government. From that time to the date of the armistice the owners were not allowed to go inside their own factory buildings. Their connection with the plant was limited to one small office, in which they could sit and receive the requisition slips the invaders handed to them. Later they were turned out of this office. They then found a small shop available and began work on an experimental model until this was discovered by the enemy and all further activities stopped.

Robbed of $200,000 Worth of Material

Altogether the Nagant factory was robbed of $200,000 worth of machinery and automobiles. Notwithstanding the close scrutiny, it was possible, in August, 1914, to hide a number of automobile parts, and efforts are now being made to get together sufficient machinery to assemble these into complete automobiles.

Throughout the entire period of occupation, the Belgian people displayed an indomitable spirit. They refused to help the enemy in any way whatsoever, and although open defiance was generally unwise, they frustrated to the limits of their power all the efforts of Germany to obtain material.

The Excelsior Factory

The directors of the Excelsior factory, at Saventhem, a few miles out of Brussels, made desperate efforts to keep their plant in running order to provide a livelihood for their workpeople. The argument was used that if the machinery were taken, the men would be thrown out of employment and starve. The directors contended that all machines were used all of the time. In order to carry out this deception, a warning bell was placed at the main door. When this bell sounded, every machine within the building was set into motion and kept running until inspectors or other visitors left the factory.

This deferred the calamity, but it soon became evident that it could not be averted. Very early during the occupation, 60 automobile tires and a large quantity of copper, brass and aluminum were hidden in the base of a chimney of a nearby factory belonging to a neutral who had fled the country. After 4½ years the tires were ruined, but there was the satisfaction of knowing that Germany had not been able to get them.

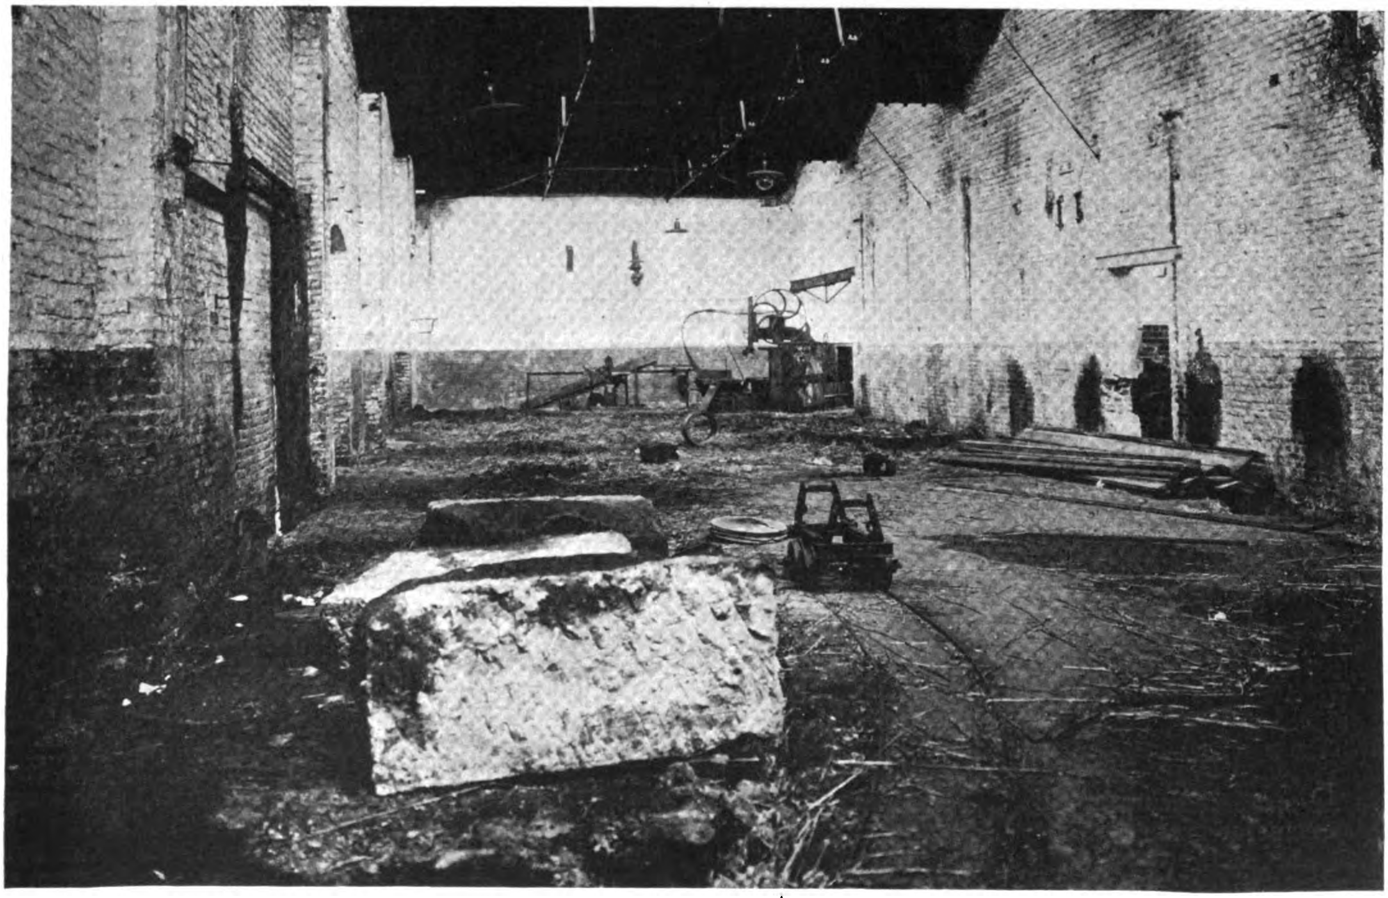
Many automobile parts and essential parts of lathes were loaded on a wagon and with the help of a forged passport were carried into Brussels and buried. This trip was made at least a dozen times over a main road closely guarded by German troops, who stopped every passerby and had the right to search whomever they liked. The men who made these trips had to pass the spot where Edith Cavell, and other victims of German barbarity, had been shot and buried.

The first lathes were taken from the Excelsior factory in April, 1915. The main removal began at the end of 1916, when the company lost everything but the hidden parts. The method of giving receipts at the Excelsior factory was very loose. In many cases a mere slip of paper, stating "one lathe, one drill press," etc., without details, without price, without signature, was all that the company obtained.

De Coninch, the Excelsior engineer, was resolved that no work should be done in his plant for the benefit of Germany; also that he would frustrate every attempt of the enemy to destroy the Belgian industry. Unable to produce, he spent practically 4 years experimenting on automobile designs. In a tiny shop concealed from the enemy, he produced a new rear axle, a gearset, suspension, and braking system and got out designs for a new type of over-head-valve engine. It was obviously impos-

Machine Shops Little Resembled Well-Fitted Workrooms

The hole in the center of this picture shows where the drophammer foundation was dug up. The hammer which featured this shop was taken to Germany



The machine shop. The stone blocks in the foreground were foundations for machines

sible to build a complete car, for the parts had to be hidden as finished. Nevertheless, all the essential parts of the two axles, the springs, the gearset and the brakes, were finished, and on the occasion of my visit to the factory I was given an opportunity of testing this roughly made experimental car, which is really remarkable in many respects. The greatest difficulty of the firm is that it has no means of production.

This experimental work was carried on in complete ignorance of what was happening in the outside world. The only technical information Mr. De Coninch received from the outside world was from an occasional copy of *Motor Age*, smuggled into Belgium through Holland.

Pipe, one of the leading Brussels firms, built armored cars until the day the German army entered the capital. When the invaders left, after the armistice, not even a file or a punch could be found in the Pipe factory.

The value of the stolen machinery is $700,000 on 1914 evaluation.

In addition to this practically all the patterns for the pre-war models have been destroyed. Unable to produce, the firm is now doing automobile repair work for the Belgian Government. Some of the stolen machines have been traced. They are as far apart as Zeebrugge, Turkey and Bulgaria. New machinery cannot be found in Belgium. Only a few days ago a man was sent out, with cash in hand, to bring back a few forges. He returned with the money in his pocket. Pipe estimates that it will be impossible to begin production in less than 15 months.

One of the finest engineering establishments in Belgium before the war was the Fabrique Nationale, at Herstal, near Liége. Being a small-arms concern, it is not surprising that the Germans treated it with severity. After having refused to work for the enemy, the managing director was deported to Germany, where he remained 4 years. The drop hammers were the first to be requisitioned, but in 1915 the whole plant was seized and every Belgian connected with it was turned out. Of the 3800 machine tools possessed by the F. N. in 1914, 3600 have been seized or destroyed. The remainder had all been listed for removal and would have gone into Germany if the war had continued another two weeks.

The total value of the material and machinery seized is $6,000,000 on a 1914 valuation.

Not more than one-fifth of this machinery, however, was used for the manufacture of F. N. automobiles, motorcycles and bicycles. Receipts were given for all material taken away, and the valuation was fairly reasonable.

When they made these seizures, in 1915, the Germans appeared to be of the opinion that they would certainly win the war, and that they could afford to act generously. After all, it cost them nothing, for not an ounce of seized material has been paid for, and all that the Belgian manufacturers have are scraps of paper of doubtful value. As in all other factories, the F. N. management is convinced that the seizures were made more to destroy a competitor than to get machinery and metal. Some of the first machines removed were handled with care, but the great majority of the tools were handled in such a way that they were seriously damaged before being taken out of Belgium.

One of the German engineers (unidentified) responsible for the destruction of the Belgian automotive industry

This photograph was obtained without knowledge of the German authorities

Toward the end of the war there were a great lack of discipline and a considerable amount of pilfering by German soldiers. The men stole magnetos and sold them to their own government. Most of the glazed bricks in the walls of the engine room were stolen by the German soldiers and sold to the German army. Just before the armistice went into effect, and immediately afterward, the soldiers offered to sell good touring cars for $100 each. In several cases, stolen F. N. cars were offered for sale by German soldiers to managers of the F. N. company.

When the German army moved across the Rhine, in November, 1918, the F. N. factory contained 200 machine tools, all of its gas engines, with the exception of one which had been wilfully damaged, the complete electric lighting installation, but no electric power equipment, and 426 German trucks in a more or less damaged condition. The buildings were not injured otherwise than by neglect.

At the present time, instead of its original staff of 4000, the F. N. is running with a staff of 1500 workpeople, who are engaged in repairing and replacing machinery and shafting and repairing abandoned German automobile trucks and staff cars. The tools left by the Germans have been united in one of the shops and are being used for repair work and for motorcycle construction. It is intended to produce first motorcycles and touring cars.

While F. N. makes little complaint about the German valuation of seized goods, the Van Den Plas body works at Brussels reports a curious case of robbery. This company had in hand 12 Rolls-Royce and an equal number of Sheffield-Simplex chassis, sent from the factories in England to have high-class bodies fitted. These were requisitioned at 4800 marks (approximately $1,200 each), although the market value at that time was $5,000 and during the war rose to nearly double the value—$9,000.

In answer to a protest the German authorities stated that in their opinion 4800 marks was all a Rolls-Royce chassis was worth. Notwithstanding the lower valuation, there was intense rivalry among the higher German officers for the possession of these cars.

In a very few cases the factories were requisitioned and made use of by the Germans for their own purposes for practically the entire period of the war. In such cases the damage inflicted was naturally less. The Metallurgique factory was treated in this way, being used as a central repair depot for the automobile service of the German army. Some machines were removed, but sufficient were left behind for the factory to be in a position at the present time to produce one car a day.

The Germain factory, on the other hand, was completely burned, while Springuel has sustained such losses that it is doubtful if the firm will be revived.

When Louvain was sacked in August, 1914, the Dyle & Bacalan factory was razed, thus depriving Belgium of practically its only automobile frame producing plant. The difficulty of obtaining frames is so great that the

Stockrooms Often Were Used as Stables and Piggeries

This stockroom of the Derihon factory was typical of factory stockrooms in Northern Belgium on Nov. 11, 1918

Even the papers and books left in this Derihon stockroom were made useless

firm has placed orders in America, and in the repair shops broken parts, which normally would be thrown away, are patched in a most unusual manner.

The entire situation is full of difficulties for the Belgian automobile manufacturer. Fully 90 per cent of the machinery is gone. Some of it has been removed to Germany, where it is being identified with the greatest difficulty. In many cases it has been completely destroyed. The manufacturers hold German receipts which, in many cases, describe the material in the vaguest manner, and in other cases give to that material a ridiculously low valuation. It is reported that the Belgian Government will shortly make an advance of 50 per cent of the value of the machinery seized; but in view of the increase in price of all material this will not represent more than 25 per cent of the present value.

Germany Should Make Good the Losses

Obviously Germany should completely refund these manufacturers and be made to return every machine that can be found.

In consequence of this condition, it is not surprising that some of the smaller manufacturers should be disheartened and should be questioning the advisability of continuing in the automobile industry. A majority of the manufacturers, however, refuse to admit themselves defeated by the Kaiser. In place of money they hold bits of German paper; the exchange rates are high; raw material is scarce; manufactured goods are hard to obtain; workers have been killed or have emigrated and those remaining are asking for working conditions equal to those of England and France. It will take at least a year to equip the factories and, in the meantime, foreign automobiles can be brought in under the pre-war tariff and France, England and America are likely to get the export trade that Belgium formerly held.

An effort is being made to induce the Government to raise the import duties from 12 per cent to 45 per cent. This proposition, however, is strongly opposed by Belgian dealers, who realize that they can only obtain foreign cars for a full year.

Undoubtedly the first firm to produce will be Minerva. This company is working hard on reconstruction and has already brought to the factory the machinery that was purchased in Holland and is beginning to receive the machines ordered from America.

While the war was in progress new designs were prepared. There are to be two models, a four and a six cylinder, each with a Knight engine, 90 by 140 mm. Among the improvements are electric lighting and starting, cantilever suspension, and spiral bevel gears in the axle. Although only high-grade cars are to be built, the demand is so great, both in Belgium and abroad, that Minerva estimates it will be fully 2 years before production will overtake demand.

Metallurgique will be early in production.

Excelsior Has Designs Ready

Excelsior has designs all ready for a very interesting new model, but is experiencing great difficulty in getting machinery with which to build it.

Most of the other firms are in such difficulties that they are glad to continue repairing army trucks and cars while getting together the necessary plant for the production of automobiles. Even if they could, by some miracle, obtain all their old machinery, they would not immediately be in much better condition, for foundries and forges throughout Belgium have been destroyed as thoroughly as the automobile factories.

Notwithstanding these difficulties, it has been decided to hold an automobile show in the Cinquantenaire Palace next December. This building, one of the finest in Brussels, was used by the Germans, for 4 years, as the headquarters of their Motor Transport Corps.

Before the war there was only one automobile truck manufacturer in Belgium, and very few trucks were in service. This was because the country was so well provided with light railroads that road transportation was at a disadvantage. Now there is an increased interest in trucks, and the Belgian representative of the English Austin company reports that he is delivering 30 3-ton trucks a week.

The Tractor Future

Before the war the horse-breeding industry was so extensive in Belgium that there was no room for the farm tractor. During the occupation of Belgium, the Germans did their best to transfer the horse-breeding industry from Belgium to the east of the Rhine, and they appear to have succeeded to a wonderful degree.

Thousands of draft horses were stolen and sold in Germany. In the city of Cologne alone, 6,800 Belgian horses were sold and the profit of 3,694,847 marks paid into the German war chest.

Dr. F. O. Waldmann, writing in *Der Rheinische Bauer*, of Feb. 2, 1918, stated that before the war Belgium exported 30,000 horses per annum of a total value of about $10,000,000. He cynically stated that by reason of the activity of the German Government the Belgian horse-breeding industry had been ruined to such an extent that for a number of years Belgium would not only be unable to export, but would have difficulty in meeting her own requirements. Germany, on the other hand, is in an excellent condition so far as horse breeding is concerned.

Because of these conditions, the Belgian engineers are turning their attention to the agricultural tractor. It has been decided that the first tractor demonstration shall be held in the fall near Termonde; it is doubtful, however, if any but foreign machines can be presented.

(To be continued)

British Aircraft Standardization

DURING the past year and a half the British Engineering Standards Association has been responsible for the preparation of all specifications for aircraft materials on behalf of the Department of Aircraft Production. During this period some 70 standard specifications for aircraft materials were issued, and a further 60 were practically complete at the time of the cessation of hostilities. These specifications were distributed to the makers by the department, as the whole of the British aircraft production was under its control. These conditions are now changing, and at the request of the Air Ministry and the Department of Aircraft Production, the British Engineering Standards Association has been requested to continue the preparation of specifications for aircraft materials and parts, as well as undertake their distribution, together with the issue of manufacturing instructions and notes on testing procedure which were formerly prepared and issued by the Technical and Inspection Departments of the Department of Aircraft Production. The request has been accepted.

It is proposed to reorganize on a peace basis the various sub-committees concerned with the preparation of these specifications. These sub-committees, when reorganized, will undertake the revision of the specification for peace purposes. In the meantime all the 200 specifications in use by the Department of Aircraft Production have for immediate purposes been adopted as interim British standards. A small charge is to be made for the standards sheets, either 2 or 3 cents per copy.

The FORVM

Follow-Up System for Engineering

By John Younger

IN reading over AUTOMOTIVE INDUSTRIES for March 6, I was interested in noting the follow-up system for engineering, described on page 539.

Without in the least way taking from Major Kalb the credit, I would point out that this particular system was away back many years before this, and is really a development of the control board, which I believe was first of all suggested by the late Dr. Fred. W. Taylor.

When the Pierce-Arrow Motor Car Co. was working on a truck to follow the May, 1917, Army specifications, the matter of getting the work through the drafting room quickly was taken up between Mr. Davis, Mr. Seelbach and the writer at the plant, with the result that we put in a control board in the drafting room, on which, first of all, a very close approach to the Bill of Material for the truck, item by item, assembly by assembly, was printed, and we then assigned a special man, whose sole duty was to go the rounds of the draftsmen and find out in exactly what state his subject was. These lines were run on progressively by this control board, which was nothing more or less than a calendar chart, so that the status of each particular subject could be immediately determined. This was carried out still further by also marking on this the progress of patterns, ordering of dies, etc.

It might interest you to know that the installation of this control board actually allowed us to design this complete new truck and get the sample through in ten weeks, which is, I believe, as fast as the Class B truck was gotten out.

This system was also introduced into the Engineering Division, Motor Transport Corps, and Major Kalb improved on it because of the large number of different jobs that we had by giving a summary for executive use.

There is no question but that this system is of tremendous value.

Military Truck Discussion

By A. P. Brush

IT is affirmed that a specialized non-commercial type of truck for military use by the United States Government has been, is and *must* continue to be a military and economic liability for the following several reasons:

As to the last war period, the designing and experimental work on the B truck and the Militor was an economic liability to the country because that work diverted a very considerable amount of expert talent from other occupations at a time when there was a critical shortage of such talent.

This work of designing and all of the experimental and production work on the B truck and the Militor were a military liability because the military forces of the country needed trucks in quantities taxing the maximum truck-producing capacity of the country, and the introduction and development of new types of truck construction at that time reduced the truck-producing capacity of the country out of all proportion to the possible service of the specialized constuctions to our military forces.

These specialized truck constructions were a further military liability in that they involved the maintenance of an additional set of parts and supplies and the familiarity of the military operating personnel with the care and operation of an additional type of construction.

The continuance of a specialized non-commercial type of truck construction for military purposes will, in the future, be a military and economic liability to the country for the following reasons:

It is an undebatable fact that, in any war emergency calling for a considerable portion of the potential military strength of the country, the need for trucks will of necessity be on a scale which will tax the total truck-producing capacity of the country.

Neglecting for the moment any consideration of the excellence or lack of excellence of a specialized non-commercial military truck design, it is a fact that no type of truck construction differing from that already in production can be substituted throughout the truck-producing plants in the country without a disastrous, temporary reduction in the production rate at a time when national safety demands the maximum.

Since any serious war emergency in the future will compel the use of a commercial truck chassis for military purposes, familiarity with the use, care and capacities of commercial truck chassis by the military operating personnel is almost, if not quite, a military necessity.

The exclusive use of a specialized non-commercial military type of truck construction in peace time will prevent the military operating personnel from becoming familiar with the operation, care and capacities of commercial truck chassis types, and such standardization is, therefore, a military liability even in peace times.

The standardization of a non-commercial specialized type of truck chassis construction for military purposes will effectually prevent the proper development of commercial truck chassis construction toward military adaptability, and such standardization is, in this respect alone, a sufficient military liability to stamp any effort at such standardization as the epitome of military folly.

It is the duty of the Society of Automotive Engineers to recommend to the Government of the United States that each year a competitive test of commercial truck chassis be held for the purpose of determining the military value of the different commercial truck chassis, and base upon the result of such test the purchase of an annual supply of truck chassis from commercial sources for the needs of the peace-time military establishment.

This policy will stimulate progress in truck-chassis adaptability to military needs, and if carried out will be of incalculable value in any future military emergency.

The policy outlined and recommended will further stimulate the development of the truck chassis in ways to make the truck production of the country of additional economic value. It will keep the military operating personnel familiar with the care, operation and capacities of the types of truck chassis which must be used in any large military emergency. It will keep the military authorities in more intimate touch with the commercial manufacturing establishments upon which the military forces of the country must rely in an emergency, and will insure a better liaison between the military authorities and the commercial interests of the country than existed during the past war emergency.

On the other hand, the proposed standardization of military truck chassis construction will mean an unjustifiable stagnation in truck chassis development both for military and commercial purposes. Such standardization will also insure a dangerous ignorance on the part of the military operating personnel regarding the use, care and capacities of commercial truck chassis.

Molybdenum in Steel

UPON the outbreak of the war the price of molybdenite suddenly rose in a remarkable degree, apparently because Germany bought it in quantity as a substitute for tungsten. During the war both England and France found themselves short of tungsten, and they, too, had recourse to molybdenum in the production of high-speed steels. Steel companies were parties to large contracts for molybdenum; but before the steel was actually put to use, the war ended.

Good Tractor Prospects in Peru

Slow-Moving Ox and Crude Plow Being Supplanted—Fuel Question Serious—Motion-Picture Advertising Effective

By A. C. Shumway*

THIRTEEN Fordson tractors are in daily use in and around Lima and one in Chimbote, a valley north of Lima, a day's run up the coast on a steamer. This latter tractor is at work on one of the estates of the President-elect of Peru, whose family owns numerous haciendas, and who will probably purchase many tractors.

In connection with the plowing, only one difficulty has been encountered, and that is that when the plow becomes worn, the point has a tendency to throw the plow upward instead of downward, and this trouble cannot be overcome by altering the attachment of the plow to the rear of the tractor. The only remedy is to attach a new plow point.

The small parcels of land, running from 7 to 20 acres, require a tractor that is easily handled and has a short turning space. With the Fordson type of tractor it is possible to negotiate most of the small irrigation ditches running lengthwise of the field, and very often it is possible to plow out an old irrigation ditch so as to level up the field.

The tractors evidently receive terrible handling on the way down here. Out of the fourteen which have been received, two arrived with the radiator top tanks broken, and the drawbar cap and foot bracket were also broken. The cases that the tractors came in were in terrible condition when they reached here. One tractor had the four sides and top completely separated from the bottom, and out of the fourteen tractors, ten had their tools taken away and one had the crank handle stolen from the crate.

Fuel Question

The question of fuel is serious here at present, on account of the very high price of gasoline, gas oil and kerosene. Although we have our own oil fields here in Peru, at Lobitos and Negritos, the price is out of all reason. It seems that Messrs. Milne & Co. have a contract with the London & Pacific Petroleum Co. that has 2 years more to run, and they claim they have to charge the price they do on account of the lack of tin cans and boxes to bring the fuel down in; they also claim that the retail dealers are to blame for the high price.

Mr. Montevon has recently taken charge of the business of the London & Pacific Petroleum Co., and I am trying to see what arrangements can be made to have the oil sold in steel drums to consumers. If this can be done we would get away from the box and can business.

The prices change almost weekly, according to the supply here in Lima, and to-day the retail prices are:

Gasoline, case	1.200	equal to	$6.00	Am. cy.
Gas oil, case	.950	equal to	4.75	Am. cy.
Kerosene, case	1.000	equal to	5.00	Am. cy.
Medium cyl. oil per gallon	.250	equal to	1.25	Am. cy.
Heavy gear oil per gallon	.250	equal to	1.25	Am. cy.
Grease per pound	.060	equal to	.30	Am. cy.

The foregoing prices are for goods in quantity; prices are considerably higher the farther away from the coast one goes. I am now endeavoring to see what can be done to get a good grade of the above placed here at a lower price.

There are quite a number of oils on the market here, as many of the larger houses carry several agencies of oil companies in the States, and they are pretty well represented through the Republic in the smaller towns. From inquiries I have received I judge that they are alive to the situation, realizing that there will be a considerable demand, and they are going after the market, so I do not think that the cylinder oil question will bother me.

I have sent a good man out with each machine of the present lot, so as to break in the help available on the different haciendas. The men stay sometimes a week and sometimes 2 weeks. There has been no trouble whatever along that line, and I must say that I am surprised at the way that the cholos have taken to the machine.

One of my strongest selling points has been that the machine could be run by the most stupid cholo, for all the other machines down here need mostly a good mechanic. As yet they have handled them splendidly, and when parties come in to have me take them to see the machines working, it always impresses them to see the way that the common help take hold and control the tractor, just as if they had been used to it all their life.

Labor Difficulties

The labor question here in the country is a very difficult one, and the tractor relieves about fourteen men, for one Fordson here is doing the work of from twelve to fourteen men, mostly plowing from seven to eight acres a day of 8 hr.—work which requires twelve to fourteen yoke of oxen, and a man for each yoke, and then the ground is far better plowed than with the oxen.

Upon the arrival of the next lot of tractors, I will send up men to the different agents, so as to set up and deliver the tractors to them. The men I break in here, on one or another of the haciendas near me, for they are all friends and are pushing the sale of the tractor just the same as if I was paying them to do so. One good point about the South American is that he is all with you or all against you.

The moving picture was and is a great success. The first time it was shown I hired the best theater in Lima, advertised for 3 days in the papers and sent out special invitations to the people interested. I furnished them with music and had a good-sized crowd. They were very much interested, as this form of advertising was entirely new to them. The film is now being shown by contract all over the Republic through some forty different picture houses, and I have received many congratulations from different parties on the splendid advertising it is giving.

Best Advertising Method

The Spanish folders I am sending to all of the agriculturists by mail, and my sub-agents are doing the same, so we will be sure to reach them all.

The best advertising is the work that the tractors are doing here around Lima, for all the Peruvians come to Lima, and at the hotels and cafés they meet and tell their troubles and what they are doing. In this way the fame of the tractor has been spread all over the country. Besides, my agents are busy, for from the letters and telegrams I have received from them I know that the tractors that are to arrive are just about disposed of, and before you receive this letter I will probably have sent in another order larger than the last.

As the business increases, I will eventually have a dealer for each of the valleys, but for the present my representatives are those given in the following list:

Paita & Piura, Graham Rowe & Co., Piura.
Eten & Chiclayo, Vda Russo Y Hijos, Chiclayo.

*Mr. Shumway is a Fordson dealer in Lima, Peru.

Salaverry & Trujillo, Sr. Tomas Morante, Trujillo.
Pacasmayo, Sr. Tomas Morante, Trujillo.
Cerro Azul, Canete, Sr. A. E. Romero, Canete.
Tambo Mora & Chincha, P. O. Macera, Chincha.
Pisco & Ica, Nazco, Palpa, G. Badaracco, Pisco y Ica.
Mollendo, Arequipa, Cuzco, C. Arenas Sucs., Arequipa.
Huancayo, Chas. Guislain, Huancayo.

I am now sending a man down through the lower valleys around Mollendo and Arequipa, taking in Cuzco, to see what he can do with the tractor, and to place other agencies where needed, for I do not want Arenas of Arequipa to lose any business on account of having too much territory. Up to the present the amount of business there has been almost nil, it being somewhat different from the rest of Peru.

We have some haciendas along the coast where the disc harrow cannot be used to advantage, on account of the very great number of stones of all sizes. I have seen them plow through a huaca that they were trying to get rid of where no one in the States would think of plowing.

Full of Stone Heaps

The Indians in the time of the Incas and for thousands of years before had the habit of clearing off the best land by placing all the stones in a heap somewhere in the field, and so Peru presents a different appearance than most countries, for many times these huacas cover an eighth of an acre and are high in comparison; the fields that I have mentioned as not using the harrow are places that the Indians could never have cultivated, for they would have piled the stones in heaps. Often they covered these heaps of stones with their fortresses and buildings made of adobe, which still exist everywhere.

The Indians numbered about 10,000,000, against 3,000,000 inhabitants to-day, and were an agricultural people, building their large heavy adobe forts and fortifications in all the valleys, the ruins of which still exist. They had a wonderful irrigation system, and coming down the valleys you will see way up the mountain sides the irrigation ditches—ditches that would do credit to a modern engineer, and must have taken thousands of Indians years to build. It may interest you to know that the potato and tomato are supposed to have come from Peru.

The natives here, when they plow with the pointed stick and oxen, so as to open up the furrow wide, always tie two horse or burro skulls on opposite sides of the plow. They prefer the burro skull to the horse skull, as the bone is harder and lasts longer.

There is a wonderful outlook for the tractor in Peru. The requirements are that it should be simple and strong, have plenty of power, be easy to run and need little attention in comparison with others on the market. The Fowler has always been the favorite here, but the cost is about $30,000 American currency, I understand; it plows about the same amount as the Fordson, but can go 14 in. deep if needed. There are two steam machines, one at each end of the field, which are connected by cable by which they pull a heavy plow or harrow. They require a horse and car to bring the water and wood for making steam, requiring ten or more men.

[In addition to the fourteen tractors mentioned in the Peruvian dealer's report digested above, the export concern of Fordson has just shipped forty-nine more to five ports in Peru. Good business is expected from this country, as considerable farming is done on all-irrigated land, and all of the work is done with the slow moving ox, as mentioned in the report.—EDITOR.]

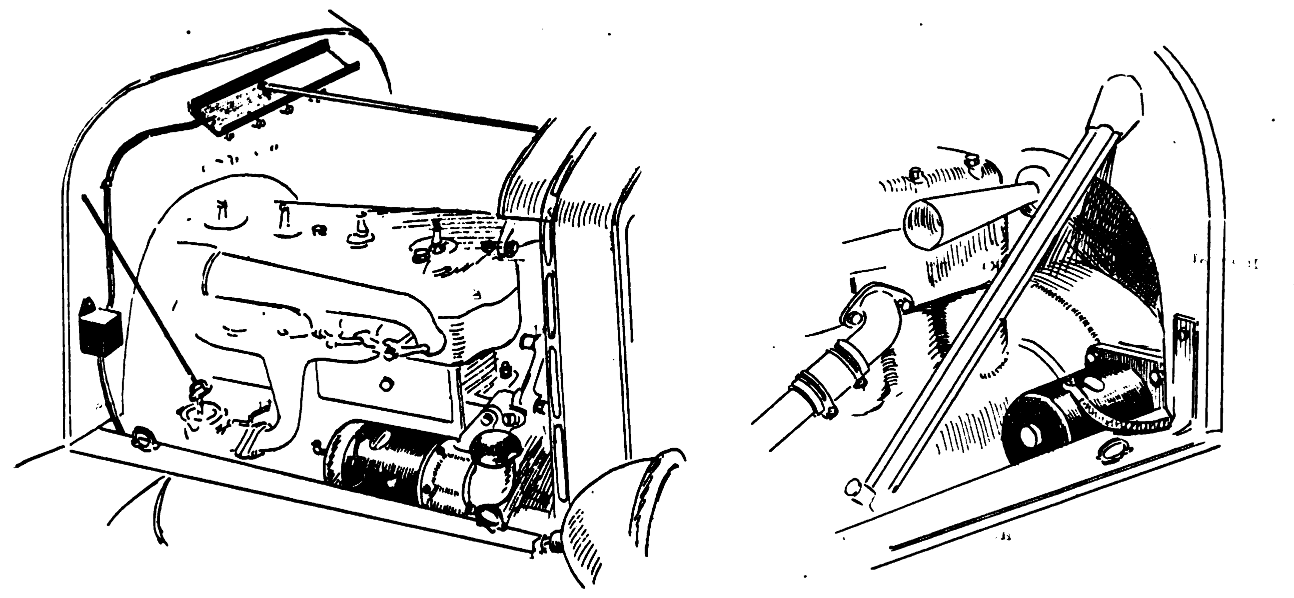
Hayne's Wearever Runningboard

THE process of rolling linotile and similar products upon board is being introduced as a means for runningboard construction by J. T. Hayne of Buffalo, N. Y. This process comprises the molding of linoleum or rubber tile on wood to the exact size of the runningboard.

The wood has on its surface numerous holes or grooves, with their walls slanting inward, into which the material is forced. This anchors a thin layer to the base and makes it impossible for it to bulge, as often occurs with the ordinary methods of laying linoleum.

Instead of a foot pad fastened to the step with several screws, it is possible with the Hayne type of runningboard to mold the foot pads into the design. It is also possible to mold into the design monograms or any other markings desired on the car, making it a factor in theft prevention as well as identification.

Installation of Liberty Starting-Lighting Equipment on New Fords



These two views show the location of the generator (left) and the starting motor (right). Both are quite small and have been built into the Ford assembly in an inconspicuous manner. The left view shows the addition of a rain gutter over the coil to prevent short-circuits caused by rain coming through the hood hinges and between the hood and cowl

Gear Steels*

Classification of Gears According to Application and According to Materials and Treatment—Properties of Gear Steels—Methods Employed in Carbonizing and Heat Treatment

By Dr. J. Heber Parker

FROM a commercial standpoint gears may be divided into three groups: Gears for automotive service; gears for electric car service; and what may be called commercial or jobbing gears.

Gears for automotive service include those used for automobiles, both trucks and pleasure cars, airplanes, tractors, motor boats, machine tools, etc. Upon gears of this group there has been devoted a great deal of study and work as regards different types of analyses and the heat treatments for each type, and also the matter of design as applied to the metallurgical side of the question, such as minimizing the matter of warpage in hardening, etc. In fact, it may be said that the story of the development of gear steels for automotive work is in great part the story of the development of alloy steels of the last 15 years with which the writer has been closely connected.

Case-Hardened and Tempered Gears

Steels for this work are divided into two groups: Steels for case-hardened gears, where there is a hard surface and soft core, and steels for tempered gears, where there is uniform hardness throughout the entire tooth section. Much has been said about the relative merits of each group. It is a long story and may be passed over by expressing the opinion that, in a general way, each has its own special field, the case-hardened gears for constant-mesh service, and the tempered gears for change or clash-gear service. Certainly the tempered steel clash gear does not realize the experience of the case-hardened gear in the same service, when hard, case-hardened clash faces are chipped off with the resultant exposure of the soft core, and consequent trouble with bearings impregnated with hard steel chips. Tempered gears have sometimes been criticised on account of pitted tooth surfaces which were found after limited service. It is believed that this pitted condition is caused by excessive unit tooth pressure due to several causes. A few experiences where the condition of pitted surfaces was corrected may be of interest:

First.—Misalignment of gears was believed to be the cause of the trouble, thus throwing an excessive load upon only a part of the tooth and vastly increasing the unit tooth pressure. When the gears were properly adjusted and the load properly distributed, pitting disappeared.

Second.—A little lower drawing temperature after hardening, which resulted in an increase of about five points in scleroscope hardness, eliminated pitting. The slight increase in hardness was sufficient to enable the gear tooth to withstand the unit tooth pressure put upon it.

*Paper read at the Cleveland meeting of the American Gear Manufacturers' Association.

Third.—The horsepower of a car had been changed without any change in the transmission. The pitting which occurred was eliminated by increasing by one-eighth inch the length of the tooth face. This increase resulted in decreasing the unit tooth pressure to a safe figure. Properly case-hardened gears, which have a scleroscope hardness of about 90, will undoubtedly withstand, without pitting, unit tooth pressures which will give trouble in the case of a tempered steel gear which is about 75 scleroscope hard. The case-hardened gear, however, is not as tough nor as strong, and in clash service has the disadvantages mentioned above. The tempered gear also will warp less in heat treatment than the case-hardened one, for it reaches an elevated temperature only once in heat treatment, and that for only a few minutes, as compared with the long high heat for carburizing, and two subsequent elevated hardening temperatures for treatment after carburizing.

Six Grades of Case-Hardening Steels

For automotive work case-hardened steels of six types are generally used, three of the types quite commonly, while the other three have a more restricted use on account of their higher cost with, perhaps, a little more careful heat handling requirements. Following you will find a table giving type analysis of each, together with the physical properties of the core, when properly heat treated, which may be expected when these steels are made by mills having more of the quality than a tonnage perspective.

The physical properties given in the table were secured by treating a standard test piece, .025 in. full to size, by heating in sand for the length of time and at the same temperature as would be used in carburizing, for the various types of steel. Test pieces were then allowed to cool in a box and given a full double treatment which would have been given a piece of the respective steels to put them in their best possible case-hardened condition. Test pieces were then ground to size and pulled.

In regard to the operation of carburizing, so much has been written upon this subject that it would be superfluous to go into it here in detail. Case carburizing compounds have been very thoroughly developed and compounds are available which will produce in the case different carbon contents—that is, 60 per cent, 80 per cent, 100 per cent carbon, etc.

Carburized pieces should not be quenched directly from the carburizing box, and this practice should not be followed, except in cases where a hard surface only is desired and nothing in the way of strength and toughness of core is expected. If carburizing temperatures are relatively low—i. e., about 1550 to 1560 deg. Fahr.—good results may be obtained by a single quench after pieces have cooled in the

Name	C.	MN.	Si.	P.	S.	Cr.	Ni.	E.L.	T.S.	El.	Red	Brinell	Sclero	Gullery Impact	Sclero of Case
Simple carbon	.20	.50	.20	.04	.04	....	....	50,000	75,000	20	55	190	30	18 Kgm	90
Mild chrome nickel	.20	.60	.20	.04	.04	.40	1.25	100,000	150,000	12	40	287	40	10	90
3½% nickel	.20	.60	.20	.04	.04	....	3.50	105,000	160,000	13	45	302	50	11	90
5% nickel	.15	.40	.20	.04	.04	....	4.75	125,000	175,000	15	50	321	54	10	90
Medium chrome nickel	.17	.40	.20	.03	.03	1.00	1.75	140,000	180,000	13	50	340	58	11	90
High chrome nickel	.12	.40	.20	.03	.03	1.25	4.00	150,000	200,000	13	52	375	60	10	90

carburizing box and have again been reheated to the proper temperature. For best results, however, a double quench after carburizing is desirable—the first quench from a temperature sufficiently high to refine the core, which is low in carbon, and the second quench at a proper temperature to refine the case, which is very high in carbon. Drawing after final hardening is desirable to relieve hardening strains and to secure increased toughness.

Warpage of case-hardened gears, as a result of heat treatment, always occurs to a greater or less extent. The warpage will be somewhat reduced if care is taken to anneal forgings before machining.

Forgings as they come from the hammer, and cooled under varying conditions, always have some internal strains. The release of these strains, by annealing, leaves the metal in a state of rest which makes possible a decrease in warpage in the finished pieces, for without the annealing, the strains in the metal, due to forging, often are relieved during the case-hardening operations, with the result that they are the direct cause of some of the warpage frequently experienced.

Tempered gears are made principally from four types of steel, two of which are in common use, while two types are more rarely used, especially one of the latter, an air-hardening chrome nickel steel, which has been used very little in this country. The table [on page 1220] will give you the type, analyses and physical properties of these steels in gear condition.

In addition to these standard types there has been sold a silico-manganese steel of approximately .50 per cent carbon, .75 per cent manganese and 1.50 per cent silicon, which has, when hardened and drawn for gear condition, an elastic limit of approximately 225,000 lb. per square inch. This steel when properly hardened remains practically constant as to size, and has proven most satisfactory as a steel for clash or change gears.

[The sections of Dr. Parker's paper dealing with gears for electric car service and gears for commercial and jobbing work are here omitted.—EDITOR.]

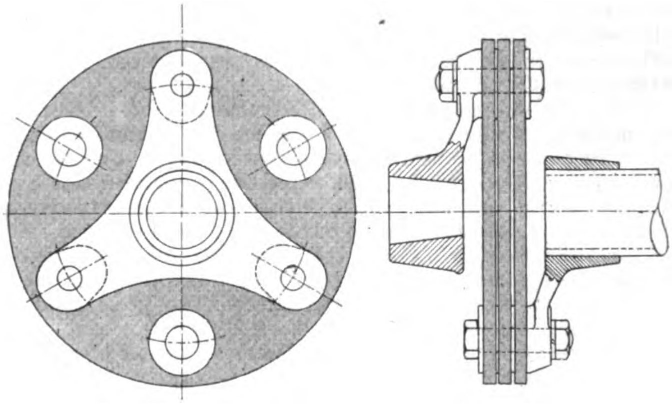
Layout for Flexible Universal Joints

THERE has been considerable discussion from time to time regarding proper layouts in connection with the flexible type of universal joints, such as the Thermoid-Hardy. The accompanying layout is typical, and has given good results on cars such as the Lexington Howard, Crow-Elkhart, and the Stewart trucks made in Buffalo.

The couplings are made up of laminated Hardy disks, and, as shown in the layout, consist of three disks, each joint having an overall diameter of 7 in., and being ¼ in. thick. This joint is capable of taking care of ⅞-in. lateral movement. Considering two joints for the propeller shaft, this would give each set of disks a movement of 7/32 in. each way, making a total of ⅞ in. play for the two joints.

The purpose in providing this range of lateral movement is to eliminate the use of splines on passenger cars wherever possible. In order to successfully do this the springs must be so flat that the lateral movement is within the limit of the joint. This is in line with present tendencies, as spring layouts are becoming flatter.

The coupling shown will stand an average driving angle of 6 deg., with a maximum of about 10, according to the manufacturers.



Typical layout of Thermoid-Hardy joint calculated to do away with sliding joints in cars with flat springs

Van Sicklen Chromometric Temperature-Corrected Tachometer

DURING the period of the war, the Van Sicklen Co. of Elgin, Ill., manufactured for the U. S. Government an instrument specially developed for airplane use, known as the Van Sicklen Type B tachometer. Tests are said to have shown this to be a highly accurate instrument. It measures either shaft speed or surface speed, indicating the shaft speed in revolutions per minute, and the surface speed in linear feet per minute. No watch is necessary in taking a reading.

The dial of the instrument is divided into hundreds. Revolutions per minute are registered up to 2500, and feet per minute up to 1250. By means of adapters it is possible to apply the instrument directly to the moving member. It takes just one second until the first reading can be taken. The indicating hand is held at this point for a second, is then released, and a new reading is given, showing whether the speed of the moving member has either increased or decreased during the interval. When the instrument is removed from the moving member the hand returns to zero.

These instruments are being manufactured in the works of the Elgin National Watch Co., which fact is being pointed to as a guarantee of their high-class construction. Two adapters are regularly furnished with each instrument, one of which transmits one-half the speed of the moving member to the instrument, the other the exact moving member speed.

The Van Sicklen tachometer comprises a complete watch mechanism, its principle of operation being that the counting mechanism is allowed to run for one second, and the number of revolutions made by the driving member during that period is indicated. The mechanism really divides into four parts, namely, 1, the driving mechanism, which takes the power from the flexible shaft and transmits it to the power plant; 2, the power plant, which furnishes power for driving the watch mechanism; 3, the counting mechanism and the synchronizing cam, which latter times the action of the counting mechanism; 4, the watch mechanism which times the action of the synchronizing cam and the counting mechanism.

Attendance and Turnover Records of Women Workers

A Comparison of the Lost Time Factors with Male and Female Operators—The Effects of Illness, Hours of Labor and Idle Shop Time—The Value of Rest Rooms and Rest Periods

IN considering the employment of women in industrial occupations, a factor which must be reckoned with is their attendance record. In the past, industrial experience has generally indicated that in this particular women employees fall below the standard set by men.

An analysis of the attendance records of 115 establishments in which an investigation was recently conducted by the National Industrial Conference Board disclosed that in 44 of these establishments the attendance of women employees is better than that of men. It is worse in 31 of the 115, and, in the remaining 40, there is little to choose between the records of the two sexes. The establishments in which the attendance of women was worse than that of men employed a total of 18,045 women, while those establishments in which women's attendance was better than men, employed only 10,481. The establishments in which the attendance records of men and women were equal, employed 9974 women. In other words, it can be said that with only 27.2 per cent of the total number of women in all 115 establishments was their attendance better than that of men.

In seeking for the reasons for the variation of attendance, an analysis of the sources from which the women workers came to these establishments did not give any clew to the cause. Furthermore, the type of work performed did not, apparently, in any way explain the differences in attendance. This latter statement is borne out by the fact that practically all operations on which women were engaged were represented among those establishments reporting poor attendance of women as well as among those reporting it as good or better than that of men.

Apparently the number of women employed bore some relationship to their attendance record. In more than half of the establishments, where the attendance of women was reported as better than that of men, and in half of those where it was equal to the attendance of men, there were employed 100 or less women, whereas nearly 80 per cent of the establishments reporting a poor attendance record for women employees employed a much larger number.

It is suggested by The National Industrial Conference Board, which compiled the data used in this article, and from whose report on the wartime employment of women in the metal trades the matter here printed is very largely taken, that there is a possibility that more individual adjustment and greater attention to health factors and to morale were possible where only a few women were employed.

TABLE I.—ATTENDANCE OF WOMEN WORKERS COMPARED WITH ATTENDANCE OF MEN IN 115 ESTABLISHMENTS
(National Industrial Conference Board)

	Establishments		Women Employees	
	Number	Per Cent of Total	Number	Per Cent of Total
Total	115	100.0	38,500	100.0
Women's attendance better than men's	44	38.3	10,481	27.2
Women's attendance equal to men's	40	34.8	9,974	25.9
Women's attendance worse than men's	31	26.9	18,045	46.9

While the replies to the schedule of inquiry which the Board sent out did not indicate a significant difference between the attendance of men and of women, when experience in other industries and other countries is considered, it appears that a higher average time loss because of absence must be counted among the unavoidable disadvantages connected with the employment of women.

Attendance of Married Women

Contrary to rather generally expressed opinion, it appeared that attendance of married women was fully equal to that of younger unmarried girls. The following table summarizes the information secured on this point:

TABLE 2.—ATTENDANCE OF MARRIED WOMEN WORKERS AS COMPARED WITH SINGLE WOMEN, IN 76 ESTABLISHMENTS
(National Industrial Conference Board)

	Number of Establishments	Number of Women	Number of Married Women	Per Cent of Married Women to Total Number of Women
Total	76	15,666	2,222	14.2
Women's attendance better than men's	33	4,965	575	11.6
Women's attendance equal to men's	23	3,488	723	20.7
Women's attendance worse than men's	20	7,213	924	12.8

No significant data were submitted in respect to the relation of illness to attendance of women workers. There is little doubt, however, that their poor attendance is largely due to illness. One-sixth of the women leaving their employment in a large machine tool plant gave poor health as their reason, a much larger proportion than among men.

Experience in Germany on this point is of interest. Data collected by the Leipzig Sick Benefit Society from 1887 to 1910 show that, among metal grinders and polishers, women averaged 1456 days of sickness compensated for per 100 members as compared with an average of 1215 days for men; among iron founders and machinists, women 1666 days; men 1189. The compensation records of German Sickness Insurance Societies from 1903 to 1908 indicate a 3 per cent to 5 per cent higher average time loss by women in most occupations than by men.

While these German figures include accidents they nevertheless indicate a higher illness rate among women.

The experience of a benefit society maintained in a large American silk factory is also significant. In March, 1918, $1,124.35 were paid in benefits to 1079 women members as against only $761.75 to 1843 men members. For the entire period from November 1, 1910, to March 31, 1917, the claims paid to men amounted to only $91,580.35 out of their contributions of $116,686.76, while the claims paid to women were $87,592.51, more than twice their contributions of $41,640.04.

A comparison of days lost through illness in 1914 by approximately 16,000 employees of the Government at Washington, D. C., over 4000 of whom were women, showed that the women averaged 8.90 days per annum, the men only 4.82.

All these figures indicate either more frequent or more serious cases of illness among women than among men.

Although poor attendance was frequently a disadvantage connected with women's employment, the greater stability of the female labor force offered some compensation. Of 94 employers reporting the comparative labor turnover of women and of men, 8 found that women's record was worse, 26 that it was equal, 60 that it was better, often by 20 per cent to 30 per cent.

A frequent comment by employers is that women are "steadier than men."

One reason advanced by some employers for the smaller turnover among women employees was their superiority to the class of men at present available. Another important consideration is that skilled men now have more opportunities to better their position by reason of keen competition for their services, and therefore are tempted to change from one factory to another.

Among the elements favoring stability of women employees has been the practically unlimited supply. Women, once secure in their positions, were naturally conservative about changing, and the sharp competition in the labor market reinforced this tendency. But the generally observed disposition of women to take their work and its surroundings more personally may, by proper organization of the factory, be made a valuable auxiliary in the reduction of labor turnover. Again, the home associations of women are more likely to restrain them from seeking employment beyond a limited field, since they usually feel a greater reluctance about breaking domestic ties and frequently have stronger social motives for remaining in their accustomed environment.

High Wages Cause Dissatisfaction

Yet an analysis of some of the cases reported indicates that with women, as with men, an increase in the demand for workers will be accompanied by a more active labor turnover. One manufacturer stated that high wage rates are making his women workers dissatisfied and that they are "trying out every job possible until they find something that suits." The treasurer of an establishment manufacturing machine needles reported a marked shortage of girls and a labor turnover of female employees 20 per cent higher than that of men. In a bolt and nut factory in Cincinnati it has been found necessary to hire twice as many women as men to maintain the force in a department where the majority of the women employed are working. Moreover, since a shortage of female labor is reported in many cities by the United States Employment Service, competition for women workers, unless regulated, will naturally increase, especially for those who have acquired some degree of mechanical skill. Nevertheless, even if radical industrial changes rendered women workers as much valued and sought after as men are at present, it is probable that both social conditions and psychological characteristics would restrain them from shifting from place to place as freely as men.

Working hours of women employed in industrial plants are limited by law in most states of the Union. The following list shows the daily and weekly maximum hours prescribed by law in states where the establishments included in this investigation are located.

TABLE 3.—LEGAL LIMITATIONS OF WORKING HOURS FOR WOMEN IN STATES WHERE THE ESTABLISHMENTS INCLUDED IN THIS INVESTIGATION ARE LOCATED

State	Daily Hours	Weekly Hours
Indiana	No limit	No limit
Iowa	No limit	No limit
Illinois	10	..
New Jersey	10	60
Connecticut	10	55
Wisconsin	10	55
Massachusetts	10	54
Pennsylvania	10	54
Rhode Island	10	54
Michigan	9*	54
Minnesota	9	54
Missouri	9	54
New York	9	54
Ohio	9	50
California	8	48

*As an average; 10 in any one day.

Table 4 shows the weekly nominal hours of work for women reported by 106 establishments, arranged geographically. In many establishments the hours for women were shorter than for men.

TABLE 4.—WEEKLY NOMINAL HOURS* OF WORK FOR WOMEN IN 106 ESTABLISHMENTS, BY STATES

(National Industrial Conference Board)

Geographical Distribution	Total Establishments	56 or Over	55	54	53	52	51	50	49	48	Under 48
Total	106	2	11	27	1	7	1	32	5	16	4

*In a very few cases hours are fractionally greater than indicated in the heading
†One establishment shorter hours in summer.
‡Two establishments shorter hours in summer.

This table shows that in 57 establishments women were working not over 50 hr. per week, while in 49 they were working longer hours, in most cases either 54 or 55. In 58 establishments in those states where a legal limit is set, women are working fewer hours than the law allows. The number of establishments reporting women employed on night work was almost negligible.

The following table, showing weekly nominal hours of work for women in the same establishments, by industries, makes it apparent that the specific industry as such had little influence on the length of the working day for women, since in each of the industries included the hours of work varied widely.

TABLE 5.—WEEKLY NOMINAL HOURS* OF WORK FOR WOMEN IN 106 ESTABLISHMENTS, BY INDUSTRIES

(National Industrial Conference Board)

Industry	Total Establishments	56 or Over	55	54	53	52	51	50	49	48	Under 48

†One establishment shorter hours in summer.
‡Three establishments shorter hours in summer.

The character or arrangement of work in many industries leaves more or less time during factory hours when employees are not engaged in actual physical effort or in concentrated attention.

An attempt was made to secure data on this point concerning women employees in the metal trades, but a question regarding the actual time lost because of pauses, waiting for stock, changes in tools and machinery, and similar interruptions, met the general response that the length of such delays was difficult to determine and that any statement must be based only upon estimates. No accurate data are available, but estimates by manufacturers place the loss from zero up to 25 per cent, and in one case, 50 per cent; they most fre-

quently ranged from 10 per cent to 20 per cent. The proportion varies, of course, in different occupations. In a machine shop where the average time lost was estimated at 20 per cent, it was put as high as 40 per cent for gear cutting operations and at 10 per cent for small turret lathe work. A manufacturer of electrical equipment who has had large experience with women workers for a number of years stated:

In setting tasks for women it is our practice to allow an average of 20 per cent for lost time. This allowance varies according to the nature of the work from 15 per cent to 25 per cent, but we believe 20 per cent is a fair average.

A machine tool establishment where women perform all kinds of machine and bench work reported as a rough estimate that for about forty-five minutes per day of 9 hr. women employees are not engaged in actual physical effort. A very small part of this was attributed to waiting for work or stock, or to delays caused by the management, but the loss was largely due to ordinary relaxations attending employment.

On the other hand several establishments reported the proportion of idle factory time as practically negligible. In one plant women performing machine operations were shifted to bench work during repairs or setting up; in another, extra machines were available. In other cases, routing of stock was so carefully planned as to reduce delays to a minimum.

It should be remembered, however, that where no provision is made for systematic rest periods, chance pauses contribute to the recuperation of the employees. Furthermore, such time losses are also common where only men are employed.

Rest Periods

The relation of regular pauses during work hours to output and to avoidance of accidents is receiving increasing consideration by students of labor problems as the importance of the subject is made more evident by scientific research and practical experiment. Rest periods are evidently of special importance for women. Of the 127 establishments furnishing data for this investigation, only 20 were maintaining systematic rest periods; in three others they had been tried but discontinued. Several other manufacturers stated that they were seriously considering their introduction. The total number of women employed by the 20 firms was 18,546, of whom 14,954 were in 6 establishments manufacturing munitions.

In most of the factories where rest periods have been established, the pause varies in length from 5 to 15 min., usually in the middle of the forenoon and afternoon. In one factory a 10-min. rest period is allowed in the morning; in another, 10 min. near the end of the day; in a third, the women are at liberty to leave their machines two or three at a time for a lunch period once in the forenoon. It is doubtful whether the full benefit of the practice is secured by the last method, since the time allowed is not definitely specified, and there is danger that ambitious workers will cut short or omit the pause allowed.

In some establishments light physical exercise or recreation such as music or dancing is combined with rest periods.

The length and distribution of rest pauses is sometimes determined by the character of the work. For instance, in a munition factory where women are engaged on operations which involve close concentration and considerable eye-strain, a rest period of five minutes is allowed at the end of each hour.

Many of the opinions expressed were favorable to the plan of two rest periods a day. An establishment manufacturing cash registers reports:

We have recess periods of 10 minutes in the morning and 5 minutes in the afternoon. We have had this plan in operation a number of years and are thoroughly sure that it is profitable to the employees as well as to the company.

A plant making machine tool fixtures, with 140 women at work, reported:

We allow women employees 15 minutes rest in the forenoon and afternoon. They also stop work 5 minutes earlier at noon and 10 minutes at night, making 45 minutes in all; we find it works out very satisfactorily.

In numerous establishments where no regular rest periods are arranged, the understanding is that women workers may rest when they feel it is necessary.

An automobile manufacturer stated:

We have not inaugurated rest-periods in our factory; but the women in our employ are at liberty to leave their work at their pleasure. Where it is necessary, we have utility women to fill in in such cases.

A compulsory rest period would probably be of greater advantage to both employer and employees. Workers take rest periods, whether they realize it or not, but often at irregular and ill-chosen intervals. Moreover, women are generally reported as more inclined than men to overwork, and the temptation of a high piece rate may lead them to continuous overexertion which ultimately contributes neither to the output of the establishment nor to the health and earnings of the worker.

In some other factories rest periods of an indefinite character are under control of supervising matrons in the different departments, who look after the general physical welfare of women workers.

In the majority of establishments making no specific provision for rest periods, apparently little attention had been given the subject. Usually no comments were offered, but it was sometimes stated that the work was very light, or that rest periods were not needed, or that the workers could rest when they pleased, as they were employed on piecework.

Rest Period Results Uncertain

In a very few instances employers reported no positive advantage from rest periods. A munitions establishment stated that the results were "intangible." In this case pauses were allowed only to women polishers and inspectors. A manufacturer of enamel ware employing women on dipping, labeling, and wrapping did not consider the practice of special value. In one factory where rest periods were tried but given up, the workday was proportionately shortened.

In some factories opposition comes from the employees who do not wish to lose the time from piecework. Such objections of pieceworkers do not appear to be well founded, since rest pauses do not necessarily involve a loss in production. One large typewriter factory reported:

The management has established two general rest periods of ten minutes every day, which have proved to be very satisfactory. By means of a chart plotted some time after the installation of rest periods, a slight increase in production was shown to have taken place. While it is not claimed that this is due to rest periods, it at least shows that there has been no loss in product due to this cause.

Extensive evidence, notably the experience of British munition factories, indicates definitely that rest periods are advantageous from an economic point of view both to employers and employees. In British factories tea is often served to the workers at their machines during rest periods. This custom is generally regarded as a valuable aid to output. A similar practice prevails in some American establishments, where milk is furnished at cost.

In its final report the British Health of Munitions Workers Committee said:

Pauses, well distributed and adapted in length to the needs of women workers, are of the highest value in averting breakdown and in giving an impetus to output. The Factory Acts permit in textile factories a maximum of four and a half hours continuous work; in non-textile the limit is five, but many managers believe that four hours is the longest period during which a woman can maintain continuous work at full vigor. Within this period a pause of ten minutes has been found to give excellent results, and where the spell is continued for five hours some such pause should certainly be made for a cup of tea or cocoa. It is particularly valuable in the morning spell in those numerous cases where breakfast has been hurried or omitted altogether.

In view of the favorable results obtained from rest periods, the problem calls for most careful investigation, to which employers can contribute valuable assistance by observation of the results of experiments as to the proper length of the pause and its position in the work period as well as its relation to the type of occupation and worker. Such considerations, moreover, are applicable to men as well as women workers.

Provision of such facilities as first aid and hospital rooms, rest and lunch rooms, as well as generally attractive working surroundings, is especially important where women are employed.

Effect of Water Injection on Gasoline Engines

Bureau of Standards Tests Show No Power Gain or Decrease of Carbon Deposit Except in Case of Engines with Defective Cooling Systems

THE practice of injecting water in conjunction with the fuel is quite common in kerosene engines, the object being to keep down the cylinder temperature under conditions of heavy loading and prevent preignition. In fact, it seems almost impossible to operate an Otto cycle kerosene engine and get satisfactory results without water injection. There also has been considerable experimentation with water injection (or induction) in gasoline engines, not by the manufacturers of the engines, but by makers of fuel conditioners and their customers, who believe that the injection of water will lessen or eliminate the formation of carbon deposit and increase the fuel economy.

In the development of aircraft engines the suggestion was made that if water injection had these effects it should be beneficial in aircraft work. The problem was assigned by the National Advisory Committee for Aeronautics to the Bureau of Standards, and an extended investigation was made. The tests were carried out on a Class B military truck engine, and also on a Rutenber 6-cylinder, 3 x 5-in. engine, which operated at high jacket temperature. Thus, although the investigation was made at the instigation of the Aircraft Department, the tests were conducted on a truck and an automobile engine, but the results, of course, are of general application.

Two Series of Tests Made

In a general way, two series of tests were made, one to determine the effect of water injection on the maximum power obtainable from an engine and its fuel economy, and the other to determine its effect upon the carbon deposit on the piston head and cylinder walls.

It may be recalled that the Class B truck engine is a 4-cylinder design with a bore of 4.75 in. and a stroke of 6 in. The compression ratio is 3.7 and the piston displacement 425 cu. in. Compression tests made by means of an O-Kill indicator showed an average compression of practically 48 lb. per square inch at 100 r.p.m., the water jacket temperature being 131 deg. Fahr. In the tests this engine was connected up to a 125-hp. Sprague dynamometer, by means of which the horsepower output was measured.

In the first test the Class B engine was fitted with a Zenith L-6 carbureter. Each series of tests consisted of three runs. After the engine had been brought up to operating temperature the carbureter was adjusted for maximum engine power at full speed, only gasoline being fed into the cylinders. After the engine had been run 5 min. under these conditions, another run was made with water injection, with the same carbureter and spark setting. Finally, during the third run, also of 5 min. duration, the water injection was continued, and the spark was adjusted to give the greatest engine output. Series of tests of this kind were made at speeds of 400, 600, 800, 1000 and 1200 r.p.m. The water was admitted to the manifold at a point 1¾ in. above the throttle valve, and the amount of water fed was read off from a graduated glass cylinder of 1000 cu. cm. capacity, while the time was taken from a stopwatch. A stopcock in the line between the graduated cylinder and the intake manifold permitted of controlling the water feed.

Three complete series of tests, each covering the whole range of engine speed, were run with the Zenith carbureter. In the fourth test a Stromberg N-3 carbureter, with a 1 5/32 in. choke and a 0.0635 in. bleeder, was substituted for the Zenith, this carbureter permitting of varying the fuel mixture for different speeds. Thus, the effect of water injection could be studied when the fuel mixture was adjusted to be as lean as possible consistent with smooth running, and also when a rich mixture was being fed. In one of the runs a metal plate, with asbestos gasket, was inserted between the intake and exhaust manifold, so as to shut off some of the heat flow from the exhaust to the inlet manifold and permit of determining the effect on the operation due to the lower temperature of the mixture thus obtained.

The final tests with the Class B engine were made under spark-and-throttle conditions simulating road-operating conditions of the motor truck.

Amount of Carbon Deposit

One of the chief claims made for water injection in gasoline engines has been that it reduces the amount of carbon deposit and that it will even remove deposits already formed. In order to test the validity of this claim, a Rutenber six-cylinder, 3 x 5-in. engine was mounted on the test stand and fitted with a fan brake to load it down. Cooling water was circulated by gravity, and in order to form a carbon deposit of some thickness the engine was run for several days with a rich mixture, late ignition, and low jacket temperature. Occasionally oil was injected into the cylinders. At the end of the 6-hr. period, all interior portions were covered with a substantial layer of carbon.

The engine was then run for another 6-hr. period under wide-open throttle, water being injected into the manifold as in the previous tests. During this run the waterjacket temperature was kept high, the outlet temperature being maintained constant. At the conclusion of this run the cylinder head was removed and the carbon deposit in the combustion chamber examined, but no noticeable effect was found. Other similar tests were made, the rate of water injection and the temperature of the jacket water being varied. The rate of water feed varied from 2.4 pints to 7.05 pints per hour. With the higher rates of water feed the engine power output was noticeably decreased.

The results arrived at have been summarized by the experts of the Bureau of Standards somewhat as follows:

No appreciable effect is produced upon the power, fuel economy and general operation of a gasoline engine by the injection of water into the cylinders at rates varying from 0.03 to 0.44 lb. per brake horsepower-hour. When water is injected at a higher rate than 0.44 lb. per brake horsepower-hour there is an appreciable decrease in the power output, fuel economy and smoothness of operation. It is quite probable that in a badly carbonized engine, or an engine of defective design, in which there are hot spots that cause preignition, the injection of the water results in an increase of power. In an engine operating at high waterjacket temperature the injection of water in amounts between 2 and 8 lb. per hour produces a softening and slight reduction of carbon, this reduction not exceeding 25 per cent and being most noticeable on the piston heads and valves. However, water injection at the maximum rate also causes a considerable reduction of power.

What Return of Railroads Means to Automotive Industry

Shippers Expect Improved Relations to Result—Hope for a Slight Reduction in Rates—Increased Efficiency Is Anticipated When Competition Is Resumed

By Allen Sinsheimer

"The railroads will be handed over to their owners at the end of the calendar year."—PRESIDENT WILSON'S *Message to Congress.*

WASHINGTON, June 2.—What does the return of the railroads mean to the automotive industries? Their return to their owners is practically assured by President Wilson's message and the well-defined sentiment of members of Congress. Under the existing law the President may return the railroads without the aid of Congress. The Legislature can, however, if it desires, pass legislation before the end of the year which would continue the Government control despite the Presidential declaration; but this is not anticipated. There is an almost universal demand that the roads be returned to private control.

The control over the roads by the Government had broad effect on automotive shipments. There has been an unprecedented rate increase. The time of shipments has increased. There has been remarkable improvement in car service supply. There has been a loss in general efficiency despite this one improvement.

The lack of competition, with a consequent lessened eagerness to give service as an inducement to hold business, is the chief disadvantage resulting from Government control, according to traffic managers. They do not like the present system, which lacks the keen competition of the past, when railroads vied with one another for business, and as a result were constantly improving service. For example, the freight shipments to-day are frequently from 24 to 36 hr. slower than in 1915 or 1916. From Detroit to St. Louis, for instance, it requires four days now, as compared with three days before Government control. Traffic managers find it useless to appeal for improvement. They find themselves as helpless as the ordinary citizen who attempts to purchase a postage stamp exactly one second after the closing hour of the post office. Likewise, because of a lack of competition and the zest for business which it creates, there have been arbitrary rulings, regulations and freight-rate changes made under such conditions that shippers were not allowed sufficient time to adapt their business, and were forced to comply at a loss.

Those who have studied the railroad situation recommend that the return of railroads to their owners should:

Be preceded by government legislation authorizing combinations and pooling of equipment and resources;

Be preceded by formulation of standard rates and regulations;

Contain legal provision protecting weaker roads;

Be preceded by regulation of wages;

Include strict government regulation.

Again, under the non-competitive arrangement there has been a policy of "if it doesn't go to-day it will go tomorrow." Work was discontinued on Sundays. Important trains were taken off.

The return of the roads to their owners, it is believed, will mean a resumption of the competitive basis to a certain degree, with a consequent renewal of the former business methods of constant improvement to gain new business. A number of railroads have suffered the transfer of their business to other roads under the Government management, and it is anticipated that these will be particularly keen to regain the lost trade.

The probability of a reduction in freight rates is slight. There may be a small saving effected in operating costs by the railroads under private management, as compared with Government operation, which has been costly, and this may allow some slight decrease. Wages, however, are an important factor in freight rates, and the great increases that have been awarded the railroad employees by the Government will probably stand in the way of freight-rate reductions. Some idea of the increase in freight rates can be gained from the following comparison:

Automobile Freight Rates Per 100 Lb.

	1914	1916	1919
Detroit to New York..........	64.5	67.5	97
Detroit to St. Louis............	50.5	53	87.5

Under private control, freight rates will again be determined by the Interstate Commerce Commission, instead of by railroad officials, and this is expected to result more favorably to shippers. Under the existing plan, local boards in certain districts comprising three railroad men and a minority of two shippers determine the rates, and the shippers have found themselves at a complete disadvantage because of their minority.

One of the most important advantages that automobile shippers have found under Government control is in the distribution of au-

tomobile freight car equipment, due to the fact that the Railroad Administration placed representatives in each shipping center to allocate the cars. This arrangement, combined with the fact that the Administration ruled against shipments of partly filled freight cars, has created a surplus of shipping equipment.

Under private control, any such plan whereby freight cars would be pooled and apportioned would be in direct violation of the existing anti-trust laws, and consequently shippers are urging Congressional legislation which will allow the private owners of railroads to combine and pool their resources on a plan similar to that employed by the Railroad Administration. If the railroads can pool certain resources, shippers urge every advantage developed under Government control will continue under private control, together with the other advantages of competition which were lost under Government supervision.

Shippers expect the return of the railroads will:
Increase the general shipping efficiency;
Bring slightly lower freight rates;
Improve the time of shipment between points of shipment and destination;
Create better personal relations between shippers and the roads;
Renew the constant improvements in service that existed under the competitive plan.

That there must be legislation before the roads can be returned to private owners has been recognized by practically all authorities. The speeches before the U. S. Chamber of Commerce convention at St. Louis, by W. B. Hines, Director General of the Railroad Administration, Senator A. B. Cummins, and the report of the Chamber's Railroad Committee, all advocated legislation permitting reasonable competition and a consolidation of the railroad systems that would enable the merging of the weaker roads with stronger ones, thereby leveling the inequalities of costs and revenues. This would mean the formation of all roads of the country into eighteen or twenty systems, under private control, but regulated to an extent by the Government.

Railroad owners object in part to this plan. They desire legislation authorizing combinations, but prefer to be allowed to form voluntary combines. As a permanent solution of the railroad problem Mr. Hines suggested that the railroads should have a fair return on the fair value of their property. This value must be determined before the necessary legislation can be passed. Out of the 180 railroad companies operating, generally at the same rates, and regardless of operating costs, some earned 2 per cent, while others earned as much as 10 per cent, and, said Mr. Hines, legislation must provide protection for the weaker roads by some combination plan whereby certain strong roads will be obliged to absorb or work in conjunction with the less profitable systems.

Merging of Roads Would Cure Many Ills

The existing absence of standards of rates and regulations, the disparity between the profits of the weaker and stronger roads, the absence of a definite point of contact between the Government and private management and the possibilities of overcapitalization and exploitation are the problems that must enter into Congressional consideration and legislation. These can all be overcome, said the Director General, if the roads are merged into a few large competitive systems, with from twelve to twenty combinations in the three great sections of the country—the West, the East, and the South—with each combination including enough of the more or less profitable roads to equalize the situation.

There should be, he claimed, an official capitalization, Government representation on each controlling board, and standardization of rates and regulations.

The plan advocated by the Chamber of Commerce committee recommends that:

1. Corporate ownership and operation of the railroads should be adhered to under Government regulation.

2. Remedial legislation should be enacted prior to the return of the roads to their owners.

3. Public authority should be granted for consolidation of the railroads into a limited number of strong competing systems, so that each principal traffic center of the country will be served by more than one system.

4. That railroads engaging in interstate commerce shall be required to change from State to Federal corporations, with suitable provisions for taxation and police regulation by the several States.

I. C. C. to Pass on Expenditures

5. That the Interstate Commerce Commission should be authorized to pass upon expenditures of capital in excess of a stipulated amount by the roads and to determine the conditions of the issuance of securities.

6. That the Interstate Commerce Commission be given authority to regulate intrastate rates when those rates affect interstate commerce.

7. That rates and fares fixed by the Interstate Commerce Commission must by law be sufficient to yield the companies a fair return upon a fair value of the property, the value to be determined by public authority.

8. Legal enactment of rules of profit sharing whereby railroads will turn over excess profits to be used to strengthen the credit of all railroads and make them more efficient.

9. That a Federal Transportation Board be created to develop transportation by rail, water and highway.

The Chicago & Northwestern Railroad and the Chicago & Great Western Railroad were pointed out by Senator A. B. Cummins as examples of weak and strong roads and of overcapitalization. The Chicago & Northwestern, which is capitalized at $46,000 per mile, has an average net operating income of 6.13 per cent on its property investment account, while the Chicago & Great Western, capitalized at $77,000 per mile, has an income of 1.77 per cent. "It requires no argument," stated the Senator, "to convince one that the Chicago & Great Western company cannot perform its duty to the public and survive under such conditions."

He advocated a series of consolidations to merge weak roads with strong ones, a Government guarantee of a return upon the capital invested in railways, and the operation of the roads through private corporations under the strictest Government control. "The Government," he declared, "cannot operate the railroads either economically or efficiently. It costs the Government more to do anything in a country like ours than it costs anybody else to do the same thing."

Temperature Control on A-C Speedometer

New Magnetic Instrument Is Fitted With Thermostatic Compensator

New A-C magnetic speedometer with flexible shaft. Note how flexible shaft is connected to center of back of speedometer

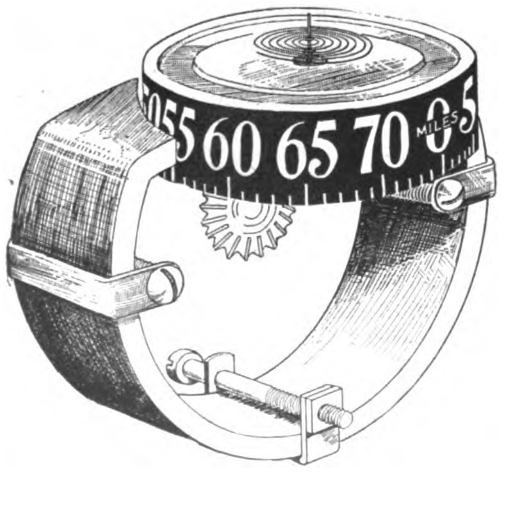
THE A-C speedometer brought out by the Champion Ignition Co., Flint, Mich., is a magnetic type of marked simplicity, and with an ingenious method for regulating and maintaining accuracy in spite of variations in temperature.

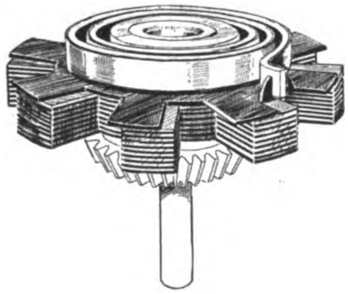
The speedometer operates entirely on the magnetic principle, having a stationary permanent horseshoe magnet held securely in the interior of the instrument in a manner which is similar to magneto and galvanometer construction. The magnet is stationary and the armature rotates within it, being driven by the flexible shaft which is connected with the driving mechanism of the car. The armature revolves in the magnetic field between the poles of the horseshoe magnet, the magnet poles being ground to receive it.

The armature is segmented into poles, the magnetic current passing through them and thrown or shunted in the direction of rotation, carrying with it a non-magnetic element in the form of an inverted aluminum cup having on its periphery the scale which indicates the velocity of the vehicle either in miles or kilometers per hour. The light weight of the aluminum cup renders it so sensitive to the magnetic drag that the instrument starts to register at a speed of 1 mile per hour. The speedometer is graduated up to 75 miles per hour, with graduations indicating every mile. The indicating element is a hair line crossing the glass window through which the speed is read in much the same way as the hair line on a slide rule indicator.

Objections to magnetic speedometers in the past have generally centered around the fact that the magnet expands in warm weather, thereby removing the poles to a greater distance from the armature. This slight variation is compensated for in the A-C instrument by an automatic thermostatic control which changes the relation of the armature laminations one to the other, thereby advancing or retarding the magnetic flux as may be necessary. In this way the speedometer will give correct reading regardless of the temperature conditions. There is an adjusting screw for making the primary setting on the magnet, and this is set at the factory and then sealed so that it cannot be tampered with by the ordinary user to throw the speedometer out of adjustment.

The construction of the instrument is such that the speed recording elements are contained in one-half of the housing and the odometer components in the other. The only connection between the two is a worm shaft which operates the odometer. The odometer will register mileage covered by the vehicle up to 100,000 miles and repeat on the total, which in this instrument is placed on the right hand side, it being considered more natural to read totals summed up to the right. The trip register, which can be reset at will, either forward or backward, to any desired figure, is placed at the left. It registers in miles and tenths of miles to 100 and repeats, the tenth figure being the same color as the unit figure, but divided by a decimal point, just as it would be read in a touring





Magnet and rotor of A-C speedometer, showing thermostatic compensator on rotor

guide book. The reset guide or button is placed in the center of the face, which makes the instrument symmetrical. The resetting knob is very much the same as the stem wind knob on a watch, and it is quick in action, requiring only a straight pull out, whereupon the reset may be rapidly made.

The two halves of the speedometer are assembled and united by a steel band forced over the broad flange surface of the instrument by pressure. The moving parts are fully jeweled, having two large jewels of sapphire and garnet. There are several design features which are unique in the instrument, a valuable point being the connection of the flexible shaft to the back, so that it can be hidden completely from view in mounting on a car. The neck to receive the shaft is concentric with the instrument and has a 7/8-18 S. A. E. (spark plug) thread. The ferrules have a tapered fit, making alignment perfect.

The speedometer is held into the instrument board of the car by a patented band clamp having slots tapered so that when turned projections go into the slots and cause a forward movement of the clamp, thereby securing it. It is locked by tightening a screw.

The front face of the instrument is metal, being die cast of aluminum, with an enamel finish of gun metal shade. The escutcheon flange is either nickel or enamel or can be made in any desired finish. The back part of the instrument is also die cast and oxidized black. The reset knob in the center is nickeled. The figures on the indicating and registering member are white on black as a standard, but can be had reversely. The Caslon type of figures are used because of the ease with which they can be read.

A special flexible shaft has been made for this instrument and greater durability and strength are claimed for it. The cable is made of alternately wound monocoil music wire of four layers, each layer having four strands totaling 3/16 in. diameter. The cable ends are secured by patented process and guaranteed by the manufacturer not to break loose. The coupling nuts are made large for good contact. The casing is of tempered material wound with two strand wire and coiled tightly to hold grease in case of severe bends and still keep its shape. All of the parts are rust proof. The flexible shaft runs at 168 r.p.m. at 10 miles per hour, varying directly with the velocity of the car, or in other words 1008 revolutions at 60 miles an hour. The travel of 1008 revolutions per mile is the basis for figuring all gearing with which to drive it.

The instrument will be standard equipment on Buicks and other cars during the coming season.

PAINTS sensitive to temperature changes are used a great deal for indicating dangerous heating in machine bearings, electric plant, etc. The double iodide of silver and copper is usually red, but blackens at 188 deg. Fahr., and again turns red when the temperature falls by the same amount.

A writer in *Die Werkzengmaschine, Zeitschrift des Vereines deutscher Ingenieure* gives a satisfactory recipe for making the paint. Copper sulphate and sodium iodide are dissolved separately in distilled water, the sodium oxide solution then being gradually stirred into the other until the deposit which at first forms disappears. A strong solution of chloride of mercury is then added, the double iodide of mercury and copper being precipitated. The deposit is filtered and dried, and is in the form of a red powder. It is then mixed with a weak solution of gum arabic, and can then be applied as a paint. Another medium is the double iodide of mercury and silver, which is light yellow when cold and turns a dark orange or brick red at about 113 deg. Fahr. This paint resumes its original color if not overheated.

Baker Two-Speed Axle

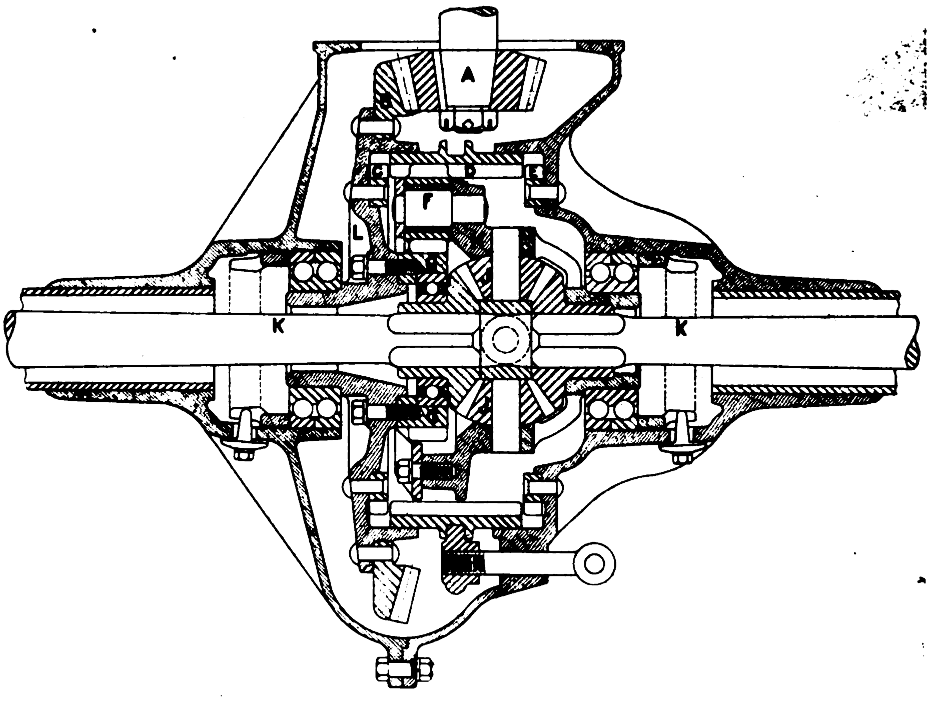
AN interesting form of two-speed axle has been invented by A. F. Baker and is being marketed by the Perfecto Gear Differential Co. of Seattle. This axle has been under test for some time on a 1-ton truck, and the maker claims that it has shown very satisfactory performance. The axle furnishes two ratios, one of 10.9 to 1 and the other of 3.9 to 1 on high speed. The two speeds are secured by means of an internal gear arrangement, as will be shown.

Referring to the section of the axle, the drive enters the axle housing at the bevel pinion *A* meshing with the ring gear in the customary manner. The ring gear *B* is riveted to carrier *L*. The annulus *D* is the chain speed gear. When it is in mesh with *C* it is in high gear and the drive is given solidly through the ring gears to the differential housing in the usual manner. When the annulus *C* is in mesh with *E*, which is riveted to the casing *M*, the internal gear action is set up resulting in the greater reduction.

On high gear the drive passes from the pinion *A* to the ring gear *B* and thence solidly through the fixed gear *C* to the annulus *D*, the pinion *F* and thence to the differential housing *H* and through the differential gear *J* to the axle *K*. This is quite similar to the usual bevel gear drive.

In low speed the annulus *D* is thrown over to mesh with the fixed gear *E*, which is riveted to the casing *M*. In this instance the drive passes from the bevel gear *A* to the ring gear *B*, which carries with it the front wheels *G*, which in turn carry with them the planet wheels *F*, rotating on the entire differential housing *H*.

Thus the double reduction is secured and the low speed ratio provided.



Lubricating Oil Program of the Bureau of Standards

An Outline of the Problems Which It Is Proposed to Solve by Experimental Research Work

A GENERAL experimental investigation of the subject of lubricating oils has been undertaken by the Bureau of Standards. A special oil laboratory has been fitted out in the Northwest Building of the Bureau at Washington and a program of experimental work has been laid down which, if carried through, should throw much new light on the subject of lubricants.

During the war the various divisions of the War Department having to do with automotive apparatus often needed information on lubricants. They found they could not get this from the oil companies, and so it was decided to install equipment at the Bureau of Standards to determine the facts at first hand. The demand for information came chiefly from the Bureau of Aircraft Construction, and it will appear from a perusal of the program that it was laid down with a special view to the lubrication requirements of aircraft engines; but we are in position to state that it is planned to make a parallel study of the lubricating requirements of other classes of automotive apparatus as well.

One thing that should make the proposed study of great economic value is the enormous waste occasioned by throwing away the oil from the crankcases of kerosene-burning tractor engines after it has served from 30 to 40 hours. This oil retains practically all its original lubricating value, and the only trouble with it is that it contains a considerable proportion of light hydrocarbons which act as a diluent. If systematic attempts were made to regenerate this oil it should lead to a great saving.

The program as printed below has been laid out under the direction of C. W. Stratford, a well-known oil expert. Mr. Stratford also selected the equipment of the laboratory. This lubricating oil section of the Bureau evidently needs and deserves the whole-hearted co-operation of the automotive industries as well as that of the oil industry.

THE PROGRAM

The general purpose of this investigation is to collect as much information as possible pertaining to the many problems involved in the lubrication of internal combustion engines. The majority of these problems have been well recognized in the past but their real importance and the necessity for their solution have been further emphasized during the war, especially in aircraft engine and farm tractor engine operation.

The secondary purpose of the investigation is to determine the real value and importance of laboratory methods now used in oil testing and of the significance of the results as an indication of the value of oils in practical service. It is hoped that new tests of value may be developed to supplement those now in use.

It is the earnest desire of the Bureau to secure the whole-hearted co-operation of oil refiners, large and small oil users and other interested parties in this investigation. All suggestions for the improvement of the program and constructive criticisms of same from all sources will be heartily appreciated.

So far as present knowledge goes the ideal lubricating oil should possess the following characteristics:

(a) Maximum reduction of friction.
(b) Minimum amount of wear of rubbing surfaces.
(c) Maximum length of time that oil can be used in service.
(d) Minimum rate and minimum amount of decrease in lubricating efficiency.
(e) Minimum carbonization in combustion chambers.
(f) The greatest security against seizure consistent with maximum lubricating efficiency.

It is proposed to determine what oil or oils most nearly approach this ideal.

Some Specific Problems

(1) To determine the cause of reduction of lubricating efficiency, i.e., whether it is due to change in viscosity alone or to the presence of decomposition products in the used oil or to both of these factors.

(2) Does the lubricating efficiency of an oil depend upon any other characteristics than those usually recorded in specifications, such characteristics as for instance adhesion, specific heat, thermal conductivity, "body," etc.?

(3) What relationship exists between the flash and fire points of an oil and its boiling point range?

(4) What predictions may be made of the specific consumption of oil in an engine from the values of the flash, fire, and boiling point range? Should the entire boiling point range or any part of the boiling point range of an oil be limited?

(5) What are the relative values of the Conradson carbon residue test and the Waters or other oxidation oven tests as means of predicting the decomposition which will occur in any lubricating oil in service?

(6) Does the presence of emulsifying products in an oil affect its lubricating efficiency in service? What disadvantage in reclamation processes are caused by the use of emulsifiable oils?

(7) Does the presence of colloidal matter such as deflocculated graphite, carbon or carbonaceous matter affect the lubricating efficiencies of oils? What is the relative value of settled unfiltered cylinder stock (which contains colloidal matter as well as solid or semi-solid matter in suspension) compared to the same cylinder stock in the filtered condition when these oils are used for blending with light hydrocarbon oils?

(8) What are suitable oils for use in Gnome or other similar types of rotary engines—castor, mineral blended with castor (using oleic acid as a binder), or mineral blended with other fatty oils?

(9) Is it desirable to blend fatty oils (high or low acidity) with mineral oils and what effect does the presence of fatty oils have upon the decomposition of mineral oils of paraffin and naphthene bases?

(10) To what extent do lubricating oils of paraffin and naphthene base, blended with fatty oils, absorb fuel vapors?

(11) How may it be judged when an oil has reached such a condition that it should be discarded or reclaimed?

(12) How may the appropriate viscosity or other characteristics of an oil for any given engine be determined, giving due consideration to seasonal changes in temperature, wear of engine parts, peculiarities of lubricating systems, etc.

(13) What are the relative merits in service of lubricating oils manufactured from paraffin and naphthene petroleums?

(14) To what extent does the character of bearing metals in contact and the condition of their surfaces influence lubrication?

Engines and Engine Test Methods

It is proposed to make tests of oils in the following aviation engines:

(1) Liberty twelve-cylinder.
(2) Liberty six-cylinder.
(3) Hispano-Suiza 150 hp.
(4) Gnome rotary.

Mechanical Conditions—Record peculiarities of engine lubricating systems, bearing clearances, specific bearing pressures, compression ratio, type pistons and rings, piston clearance and all other mechanical features of importance. The large bores in the crankshaft should be plugged with aluminum to facilitate removal of oil from system without taking down between test if desired.

Rate of Oil Flow—The oil flow from the pump to bearings will be measured by a venturi. If possible the actual rate of oil flow through all bearings should be determined at the normal revolutions per minute of engine by direct measurement.

Running Records—Barometer, temperature, inlet air, humidity.

Constant	*Variable*
(1) R.P.M. of engine.	(1) Horsepower.
(2) Fuel consumption.	(2) Oil consumption. (a) Burned. (b) Leakage. (c) From breathers (vapor).
(3) Jacket water inlet temp.	(3) Oil temp. outlet to cooler.
(4) Oil, inlet to pump temp.	(4) Oil temp. from crankpin cheeks.
(5) Oil pressure.	(5) Water temp. outlet.
	(6) Condensate from breathers. (a) Oil. (b) Volatile. (c) Gas.

Test Periods—It will be necessary to determine whether the same amount of decomposition can be obtained in 1 hr. runs as in 5 hr. or longer periods. A standard test period will be chosen for all tests.

Special Tests—(1) Fuel Absorption. Runs should be made with paraffin base and naphthene base lubricating oils using as fuels, (a) dry gasoline vapor, (b) aviation gasoline and (c) average automobile gasoline with each oil for the purpose of determining the relative amount of fuel absorbed by each and the character of the compounds absorbed.

(2) Carbon Deposits. Runs should be made with (a) paraffin, (b) intermediate and (c) naphthene base lubricating oils and a record made by photographing the piston heads and noting the amount and character of the carbon deposits on the remainder of the explosion chambers.

Standardized Test Fuel—A sufficient quantity of aviation gasoline made from the same refinery distillate should be provided for the completion of all engine tests. Whenever any change is made in fuel, then a standardized lubricating oil should be used to determine whatever variation may occur because of the change in fuel.

Standardized Lubricating Oil—It is highly advisable to standardize some lubricating oil for use during all engine tests to check any variation other than that caused by lubricating oil. A sufficient quantity of this oil should be provided to meet the requirements of all check tests.

Theory of Lubrication

Adhesion—(1) Determination of method or methods of measuring adhesion on the following groups of oils:

(a) Hydrocarbon oils of different bases, and each of different viscosities and volatilities.
(b) Fatty oils—prime lard, "acidless" tallow, castor and sperm, also same with different proportions of oleic acid, cotton-seed, etc., also cutting oils.
(c) Blends of hydrocarbon oils and fatty oils, also hydrocarbon and castor blends with oleic acid as a binder.

Study of cutting oils, and the bearing cutting oil properties have on lubrication. Power consumption for cutting operations with and without cutting oils.

Study of Oil Films—1. Behavior of films at constant temperature on plates, also on plate with temperature gradient, to determine drainage and rate of spread.

2. Behavior of films on different metals with localized heating.

3. Behavior of films on water, as a possible means of throwing additional light on the present knowledge of oil films as applied to lubrication.

Thermal Properties—Specific Heat, Heat Conductivity and Thermal Expansion on same groups of oils as given under Adhesion.

Friction Machines

The practical usefulness of friction machines in general has been widely commented upon and questioned in the past. In order to definitely settle the real value of friction machines the following program of investigation is proposed:

(1) Study of present stage of the art.
(2) The analysis of all existing machines comprising the following general items:
(a) Information is desired as to whether a reading can be made of the critical point of film breakdown, *i.e.*, incipient seizure of bearing at different loads, speeds, and viscosities at the temperature of oil film in the bearings, also when using different bearing metals.
(b) Method of applying lubricant to rubbing surfaces.
(c) Method of regulating all operating conditions.
(d) Recording devices, automatic or otherwise.

In the preparation of the above analysis it is desirable to draft a chart in which as much information as possible may be given in tabular form for direct comparison.

With all the above data at hand, then complete detail specifications should be prepared of an Ideal Friction Machine on which all determinations desirable could be made.

Division VIII, Metallurgy and the Division studying lubricants will fully co-operate with reference to bearing metals and tests.

Routine Tests

Fresh and Used Samples

1. *Gravity.*
2. *Flash.*
3. *Fire.*
4. *Viscosity.* (Saybolt Universal) at 100 deg., 150 deg., 212 deg. Fahr.
5. *Color.* 1. Fresh.
   2. After heat test.
   3. Used oil from engine.
6. *Emulsion*—Shaker (Coles).
   Demulsibility—Herschel; Stirrer.

Note—Oils more viscous than 50 sec./212° will be blended 50/50 with standardized petroleum ether for shaker emulsion tests.

7. *Cold Test*—A. S. T. M. method.

Special Laboratory Examination

Carbon Residue—Carbon residue values will be determined by means of the Conradson carbon residue apparatus as described in the A. S. T. M. proceedings. All outside oil samples and special engine test oil samples will be subjected to the Conradson test.

Oxidation Oven—All oil samples both outside and those used in special engine tests will be subjected to tests in both the Waters and Stratford oxidation ovens for the following determinations: (a) Evaporation loss, (b) Petroleum ether insolubles, (c) "Varnish"—resins.

In making a general study of the susceptibility to oxidation of engine oils full consideration should be given to constitution and methods of manufacture of anahydrous switch and transformer oils. The same remark applies to viscous "water-white" oils, such as Squibbs or Nujol medicinal oils.

Standardized Petroleum Ether—In making petroleum ether insoluble determinations it is imperative that the same standardized petroleum ether be used throughout all tests. Spec-

ifications for standardized petroleum ether are as follows:
Gravity, Baumé 77 to 80 (incidental).
Initial Boiling Point—110 deg. to 120 deg. Fahr.
Final Boiling Point—220 deg. to 245 deg. Fahr. Unsaturated content not over 4 per cent (Bureau of Mines method).

Note—Above distillation range determined by Saybolt distillation method.

Volatility—It is desirable to investigate by distillation the volatility of the different compounds contained in lubricating oils. In order to properly make this investigation it may be necessary to determine a part of the boiling point range or the whole of that range.

There are four general distillation methods applicable:
(a) Destructive distillation under atmospheric pressure.
(b) Dry distillation under high vacuum (40 to 50 millimeters Hg.).
(c) Distillation under high vacuum (40 to 50 millimeters Hg.) with the introduction of superheated steam.
(d) Distillation under atmospheric pressure with the introduction of superheated steam.

It is proposed to determine by experimentation which of the above four methods is most applicable to the study of the constituency of lubricating oils with least decomposition of oil and with the most concordant results.

Other Determinations—(a) Sulphur content, (b) ash, (c) fatty oils, (d) acidity, (e) alkalinity, (f) tarry or suspended matter, (g) moisture, and (h) odor.

List of Oil Samples for Examination

Commercial Oils—A two-gallon sample of all available American hydrocarbon oils, intended for the lubrication of internal combustion engines, will be examined for their physical and chemical characteristics. This list of oils will comprise all of those now sold in sealed containers and having reasonable distribution and volume of sales. These oils will not at present be run in the engine tests. It is proposed to purchase these samples at regular intervals, say quarterly, and to retain a four-ounce sample for reference from each of the samples purchased.

Special Oils—The following Liberty Aero Engine Oil Types will be procured and subjected to a complete examination, including engine tests. Specifications for these oils will correspond to the limits prescribed by Signal Corps Specification No. 3501.

Paraffin Base—(1) Lubricating oil made from paraffin base crude petroleum (Penna.) of high boiling point range.
(2) Lubricating oil made from paraffin base petroleum (Penna.) with low boiling point range.

Naphthene Base—(1) Lubricating oil made from naphthene base crude petroleum (Gulf Coast) of high boiling point range.
(2) Lubricating oil made from naphthene base petroleum (Gulf Coast) with low boiling point range.

Fatty Oil Blends—Fatty oil (prime lard) blends will be made with each of the two oils given above under the heading of Paraffin and Naphthene Bases. The physical properties of these blends will be made to correspond to Signal Corps Liberty Aero Oil Specification No. 3501.

The above oils have been selected to determine the difference if any in their lubricating efficiencies in service. Such differences may occur because of different chemical structure or peculiarities of refining processes applied in their manufacture.

If the data from the tests on this list of oils show marked tendencies it may then also be advisable to carefully investigate lubricating oils made from natural mixtures of paraffin and naphthene base crudes (Mid-Continent), or same made from blends of the lubricating distillates from these two crudes at some stage in their manufacture.

Miscellaneous Oils—Various special oils will be used in the study of the effect of processing methods, i. e., acid treatment, sulpho-compounds, etc. Also the effect of filtration to different colors.

(a) Prime lard, (b) sperm, (c) castor oil, cold pressed, (d) rape seed oil, (e) rape seed oil, blown, (f) cylinder stock, low cold test highly filtered, (g) cylinder stock, strained low cold test unfiltered, (h) "paraffin," and (i) acid treated oils.

Regeneration of Used Oils

It is proposed to make a study of commercial processes applied to the regeneration of used oils and to determine what is the best and cheapest means of converting used oils into good lubricants. Also to determine the relative lubricating efficiency of regenerated oils as compared to that of the same oil in its fresh, unused condition.

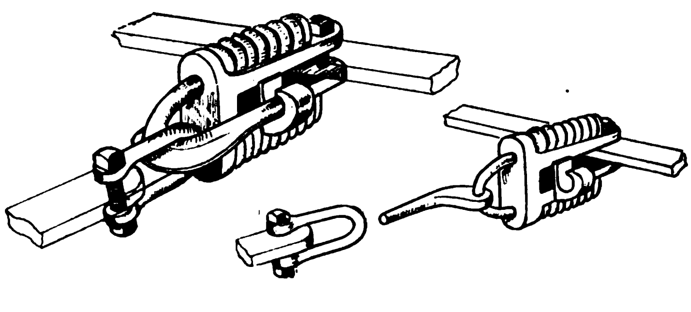
Problems Involved
1. Removal of solids in suspension.
2. Separation (distillation) of very volatile products.
3. Separation (distillation) of light oils.
4. Removal of heavy oxidized compounds by treating with soda ash and blowing with steam.
5. Removal of moisture.
6. Filtration, Fullers earth.
7. Blending filtered oil to required viscosity if necessary.

Proposed Samples for Regeneration
1. Used oils made from paraffin crudes (Pa.).
2. Used oils made from intermediate crudes (Mid-continent).
3. Used oils made from naphthene crudes (Tex.).
4. Used oils made from California crudes.
5. Used oils made from blends of hydrocarbon and fatty oils.
6. Slop oils consisting of a mixture of oils and greases.

The Greer Tractor Release Clevis

ERWIN GREER AUTOMOBILE CO., Chicago, has placed on the market a clevis for use in hitching the drawbar of a farm tractor which insures an automatic release of the implement drawn whenever the load is abnormally increased. The sketches clearly show the construction of the device. The pull is transmitted through a single-arm lever, the free end of which is normally held by a hook or catch, which can be adjusted on the clevis. Under the effect of the pull, the two coiled springs are compressed, and when the pull exceeds a certain amount the end of the lever is released from the hub and the implement is automatically detached.

This device is said to be of great value in plowing rocky fields or fields in which there are tree stumps. The position of the hook, which determines the amount of load for which the implement is released, can be adjusted at will. The clevis weighs only 17 lb.



Sketches showing Greer clevis in working position and released

Electric Arc Welder
for Portable and Stationary Use

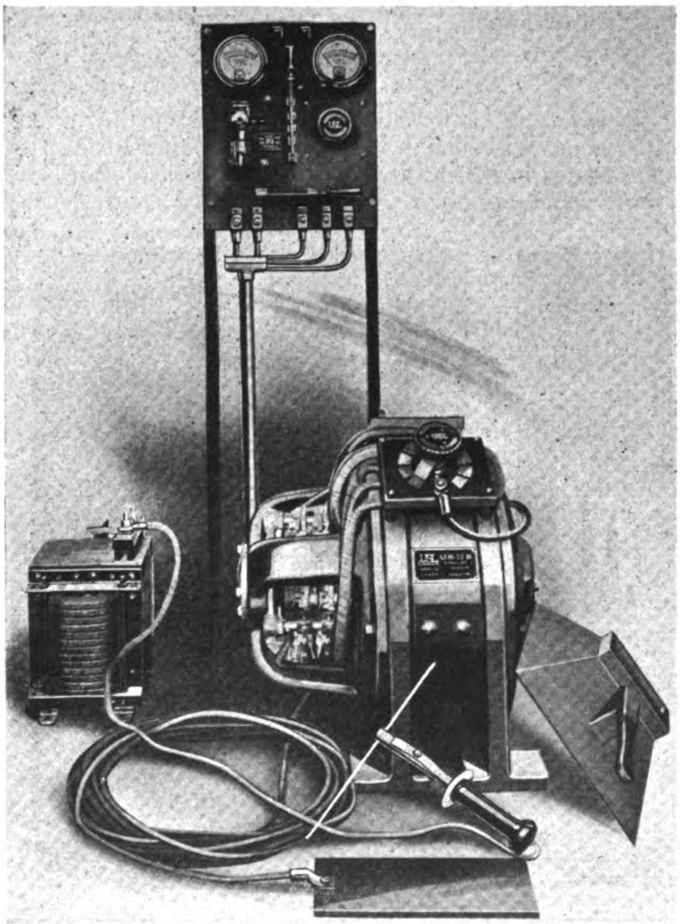
Designed for Operation on Either Direct or Alternating Current Lines, the Alternating Current Outfit Including a Motor Generator Set

AFTER an exhaustive investigation into the requirements of manufacturing institutions, garages and machinery repair shops, the U. S. Light & Heat Corp. at Niagara Falls, N. Y., has developed a line of electric arc welding machinery to meet the requirements for every character of work.

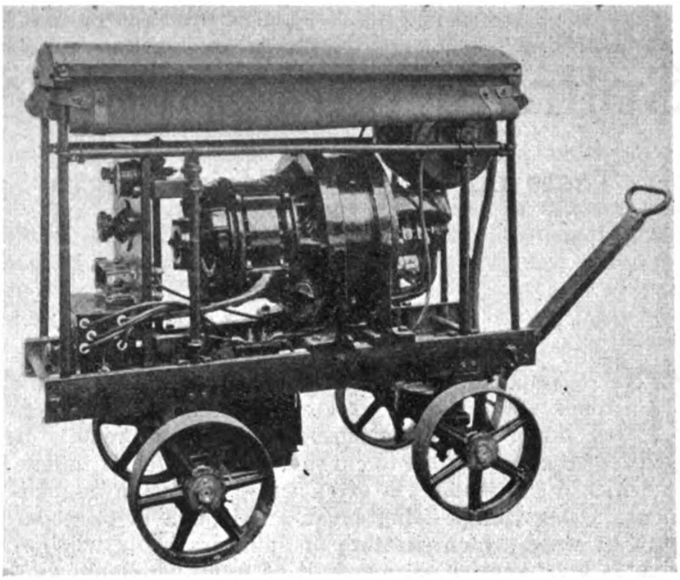
For the smaller shops where it is possible to bring the parts to be welded to within 50 or 75 ft. of the welding apparatus, a stationary type is provided. Where it is necessary to take the electric welding apparatus to the work, a portable type is provided.

The USL arc welder, as the machine is called, has a rated capacity of 4 kw. and gives 200 amperes direct current or less. It is of the variable voltage type, with a range of open circuit voltage from 35 to 65 volts. Tests of the USL arc welder show that it delivers practically constant energy throughout the range of voltage used in welding. This characteristic, together with other special features of design, keeps the arc strong and steady and aids the operator in securing a steady flow of metal into the weld.

The welder is made in the form of a converter for use on 100 to 125-volt direct-current circuits only, and in the form of a motor generator for all other circuits. The converter is inherently regulated, weighs only 665 lb. and delivers current at the arc through the arc stabilizing reactor with an efficiency of 65 to 70 per cent.



Stationary type of U. S. L. arc welder



U. S. L. arc welder in portable form

The motor-generator type of welder consists of a 7½-hp. motor mounted on the same shaft with a special 4-kw. generator. This generator is inherently regulated, compound-wound, self-excited, and has a drooping voltage characteristic which keeps the current within safe limits on short circuit. Motor-generator equipments are available in any standard d.c. voltage and in any generally standard a.c. voltage, phase and frequency.

Converter and motor-generator types are made up both for portable and for stationary use. The portable truck with cover is 28 in. wide, 55 in. high and 54 in. long. Completely equipped with motor generator, switch and metal panel, cover, cable reel and flexible cable, it weighs 1530 lb.

—

Foamy Glues

GLUE which is foamy when spread is likely to give unsatisfactory results, owing to the formation of dry spots in the joints by the air bubbles. Spots as big around as a pea are sometimes thus formed and numerous smaller bare spots are to be found in any joint made with foamy glue. Such breaks in the glue film, of course, weaken the joint appreciably. A loss of 25 per cent has been noted by the Forest Products Laboratory in the shear strength of plywood due to the use of foamy glue, and even greater losses were found when the glue coat was heavy.

Foaming in animal glues may be caused by running the spreader too rapidly, or by running it idle, or by over-heating the glue. Foaming is also dependent on the amount of grease the glue contains, the kind of stock used and the method of manufacture. Alkaline glues are more subject to foaming than glues of acid reaction. Unless a special foamless glue, which most manufacturers are prepared to furnish, is used, or some more desirable preventive measure is taken, the addition of a little grease or oil may allay foaming troubles in animal glue.

Fish oil, corn oil, mineral oil and preparations containing tallow are in use for this purpose.

Foaming in casein glue is commonly the result of mixing at too high a speed or for too long a time. Casein glue mixed at high speed may have twice the volume it would have if mixed at the proper speed, owing to the incorporation of air. Foaming is also caused by improper operation of the spreader. Blood glue has a marked tendency to foam when used in a mechanical spreader. The addition of sulfonated oils has been suggested as a remedy, and it is probable that improvements in the glue formula also will reduce the foaming tendency.

Splintering Properties of Airplane Woods

Tests on Relative Resistance to Splintering Under Rifle Fire, Carried Out at the U. S. Forest Products Laboratory

By G. E. Heck*

THE importance of determining which airplane woods will offer the greatest resistance to splintering under rifle or machine-gun fire can readily be realized when one stops to consider the shower of bullets to which a battleplane is often subjected in an engagement. Other things being equal, an airplane or propeller built of wood which shatters or splinters badly will not give as good service as one built of wood which shows a relatively small, clean-cut hole when struck by a bullet.

The determination of the relative resistance to splintering under rifle fire of some of the most common airplane woods was one of the problems submitted by the War and Navy Departments to the Forest Products Laboratory, Madison, Wis., for investigation during the war.

The laboratory investigation covered the ten species of wood shown in the table, which gives the moisture content and specific gravity of the test panels.

Three Panels Tested

Three panels 15/16 inch by 8 inches by 16 inches of each species were tested, except in the case of the mahoganies, for which four panels were used, two of high-density and two of low-density material.

Model 1898 United States Army rifles shooting 30-calibre, 220-grain, steel-jacketed ball cartridges with an initial velocity of 2000 feet per second were used in the test.

In the first series of tests the panels were placed perpendicular to the line of fire, each panel presenting a target 8 inches wide by 16 inches high. Two bullets were fired through each panel from a range of about 35 yards. The result of one of these shots is marked "S" on Fig. 1.

The second series of tests was similar to the first, except that the panels were inclined 45 deg. to the horizontal plane. The result of one of these shots is shown at "F," in the same photograph.

The third series was made with the panels hung vertically, as in the first instance, but revolved 45 deg. about a vertical axis.

Thus there were three angles at which the bullets cut the grain of the wood—at right angles to the grain, 45 deg. with the grain, and 45 deg. across the grain.

The splintering effect of the bullets on leaving the wood, in typical panels of each species, is shown in the illustrations. Fig. 1 shows a bullet hole in a wood with no splitting and small splinters. Fig. 2 shows one in a wood with considerable tendency to split and form long coarse splinters.

Results of moisture content and specific gravity determinations on test panels based on oven-dry weight and oven-dry volume, are shown in the table.

Average for Each Species Tested

Species	Moisture, per ct.	Sp. Gr.
Sitka spruce	10.5	0.41
Black walnut	12.6	0.58
Prima vera	13.3	0.47
Tanguile	15.3	0.59
White oak	15.0	0.69
Yellow birch	12.3	0.66
African mahogany		
High density	11.0	0.56
Low density	10.5	0.42
Central American mahogany		
High density	9.5	0.51
Low density	13.0	0.36
White pine	9.6	0.36
White ash	11.9	0.64

Observations show that the ten species may be divided into two groups—one in which there was very little or no splitting, or in which the splinters formed were short and fibrous; and the other in which the wood showed a de-

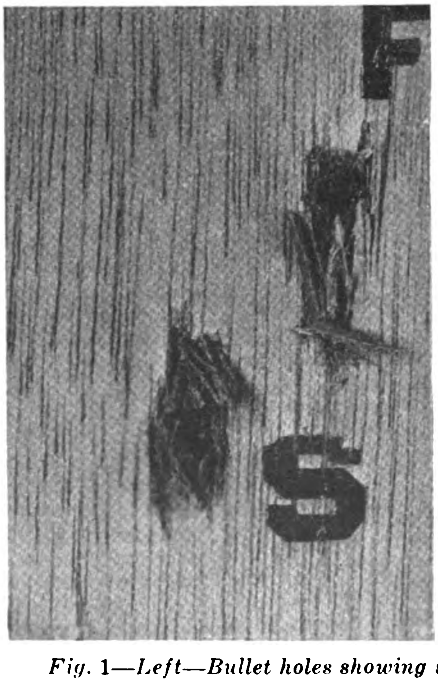


Fig. 1—Left—Bullet holes showing small splinters and no splitting. Fig. 2—Right—Bullet hole showing large splinters and tendency to split S—Line of fire perpendicular to grain; F—Line of fire 45 deg. with the grain

*Engineer in Forest Products, Forest Products Laboratory, U. S. Forest Service, Madison, Wis.

cided tendency to split, or in which relatively long coarse splinters were formed.

The two groups are as follows:

GROUP 1	GROUP 2
Woods with No Splitting Tendency	*Woods with Decided Splitting Tendency*
Tanguile,	Black walnut,
Yellow birch,	Sitka spruce,
Prima vera,	White oak,
White pine,	White ash.
African mahogany,	
Central American mahogany.	

A tendency of the wood to crack or split is indicated on the photographs by a dash under the letter designating the bullet hole.

There was apparently very little difference in the splintering effect due to the change in the angle at which the bullet entered the wood. All the panels had holes of irregular outline, and splinters of various sizes formed on the back surface where the bullets pierced the wood.

The African mahogany panels seemed to offer a greater resistance to splitting than the white oak. The splinters of the latter species were long and coarse, while those of the former were short and fibrous.

There was no apparent difference in the relative resistance to splintering between high and low-density mahogany. No comparison was made between high and low-density specimens of the other species.

Although black walnut was placed in group 2 on account of the tendency to split, the splinters formed were small and the bullet holes were not so large as those of the other species in this group.

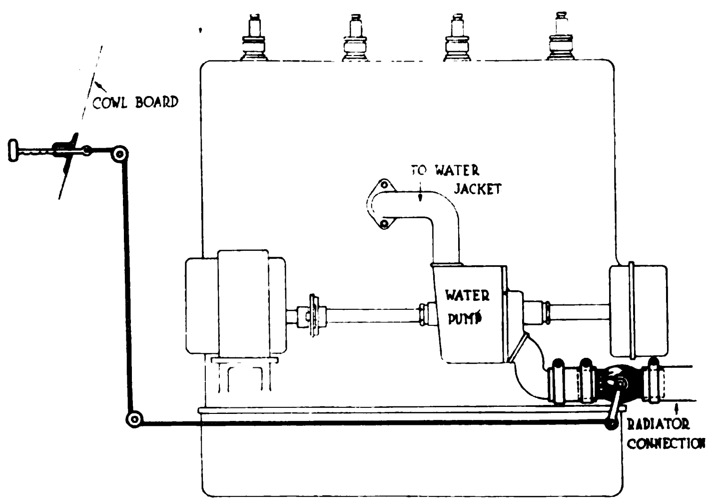
White ash seemed to split the worst and formed large splinters. The largest holes were made in the panels of Sitka spruce, although this species did not seem to split so badly as white oak and white ash.

The "Flocontrol" Cooling Regulator

TO provide an efficient, yet an inexpensive means of controlling the temperature of the engine regardless of the climate or load conditions, the Fulflo Pump Co. of Blanchester, Ohio, manufacturer of the Fulflo water circulating pump for engines and Fulflo lubricant pumps for machine tools and grinding machines, is marketing a new device sold under the trade name Flocontrol.

The Flocontrol enables the driver to regulate the flow of water through the engine and radiator, giving him control of the engine temperature. It is so arranged that the flow can never be completely shut off, a slight circulation being always maintained through the radiator, thereby preventing freezing in cold weather and the possibility of the engine heating too rapidly. The manufacturers argue that on cars equipped with a Motometer the driver has a means of telling when his engine is too hot or too cold, but he has no means of remedying the condition. Installation of a Flocontrol enables him to regulate the flow of water in accordance with the indications of the Motometer.

The Flocontrol is made in several standard sizes, so that it is applicable to any make or model of truck, tractor or passenger car. In order to install the device, it is only necessary to cut a small section out of hose connection between the radiator and the pump and insert the Flocontrol, attach the metal cords and run the cord to and attach it to the dash regulator.



The Flocontrol—diagram of installation

The device is furnished complete, consisting of the valve, regulator, necessary metal cords, eyelet screws and hose bands. It will also be furnished to manufacturers, arranged for direct connection to the water pump intake.

German Engineers in Conference

FOR the first time delegates from all the engineering institutes, trades and schools in all parts of the Empire except the occupied districts met in conference at Eisenbach recently. Among those who attended were the postmaster general, the president of the Württemberg Technical Association, the presidents and delegates of the great mining technical organizations, and representatives of the German Engineers' Association, the Electrical Engineers' Society, various chemical associations, the Society of Architects, the Railway and Postal Technical Officials, etc. The conference is a result of the revolution, which brought to realization the long-entertained plan of a meeting of the entire German technical interests.

The conference proceeded to settle its organization, especially the constitution and by-laws. It recommended that technical knowledge should have some part in all school programs of study, and that in the high schools of other professions some instruction in technical affairs should be given; further, that the people should be made familiar with the working and importance of technical ideas for economy and culture, and technical experts of the necessary personal capability and knowledge should have a greater share than before in the work of public bodies with the powers of full members.

The association will also undertake to further the civil rights of its members and adherents. It has already achieved success, in that among the members of parliament elected since the revolution the number of engineers has increased tenfold. These have been in many cases consulted by the Foreign Office in the consideration of the peace conditions, and their influence is on the increase. The limits of their competence were, however, clearly recognized by the conference, and the statement was applauded that great questions must not be regarded only from the technical standpoint. Great anxiety was evinced over the terms imposed by the Entente for the prolongation of the armistice, and the conference passed a resolution for transmission to the Government and National Assembly in Weimar, pointing out the great dangers of such concessions as the handing over of locomotives and agricultural machines, and asking that such pledges should not be made without previous consultation of the technical experts.

Class B Rules for Tractor Tests

The American Society of Agricultural Engineers Drafts Plan to Make Data Gathered at Field Trials Comparable and of Educational Value to All Branches of Industry

THE American Society of Agricultural Engineers has drafted two sets of tractor demonstration rules. The society is working to bring about uniformity in tractor demonstrations and to make these demonstrations productive of figures that will be of value to both the manufacturer and the user.

In its statement the society says:

"The object of these rules, instructions and data is to make all tractor demonstrations of this kind comparable and of educational value. Any one who has conducted tractor demonstrations in the past has realized the necessity of some standard rules to follow, and those who afterward have referred to the results deplore the lack of uniformity in the demonstrations and the data.

"The value of these demonstrations depends largely upon the accuracy of the data reported on both the conditions and results. The fuel consumption per acre, for instance, is much more interesting when the condition of the soil is known, and this varies so often in the same field that the conditions for each tractor should be carefully considered and specified in the data.

"Fuel tests should not be undertaken unless the work is under the direction of a competent engineer, and preferably representatives of the Agricultural Engineering Department of the State Agricultural College."

The Class B rules, which are printed herewith, are designed to govern State or national demonstrations conducted by manufacturers, distributers, dealers, agricultural institutions and county agricultural agents. The society also has drafted Class A rules, which are designed to govern demonstrations of a more local character. Copies of these rules will be supplied upon request to F. W. Ives, secretary of the American Society of Agricultural Engineers, Ohio State University, Columbus, Ohio. The rules are copyrighted by the society.

Data Sheet for Tractor Tests—Class B

Place of test .... Date ....

TRACTOR DATA

Name and model of tractor .... Serial No.........
Make of plow ....No. of bottoms........
Size .... Type Ben. Purpose ....
Stubble .... Sod........................

FIELD DATA

Kind of soil ....
Condition: Wet..........; Moist..........; Dry..........
Character of land: Level............; Rolling............
Previous crop grown ....

PLOWING DATA

Length of field (headland to headland), ft. ....
Width (edge to edge of furrow, less width of land plowed before test), ft. ....

Note—All lands for economy tests to be within 10 per cent of the same length. (See instructions.)

Average depth of plowing..................................
Total area plowed, acres ....
Total time of plowing.....hr.,.....min. Time out.....min.
Duration of test ......hr. ......min.
Rate of travel .... ft. per min.
Gal. of kerosene used........ Gal. of gasoline used........
Sp. gr. of fuel gas........... Kerosene ....
Water used: Radiator ....; Engine ....
Fuel used per acre:
Gasoline .... Cost of fuel per gal............
Kerosene .... Cost of fuel per gal............
Average drawbar pull, lb. ....
Average drawbar horsepower ....

Drawbar horsepower to be based upon rate of travel during fuel test.

Fuel used per drawbar horsepower hours ....gal.

Rules for Maximum Brake Test

Rules 1 and 2—Governing plowing tests of Class B, apply also to this test.

Rule 3—Time—Each entrant will be given two hours, if necessary, in which to make adjustments and trials before starting the brake test. Duration of brake test will be two hours' continuous running.

Rule 4—Fuel—The same fuel used in plowing test must be used in this.

Rule 5—Speed—The belt pulley should be run within 10 per cent of its rated speed.

Rule 6—Equipment—(a) Prony brakes will be used which will all be of the same design and will be calibrated before the tests. These brakes will be of approved design, water cooled, equipped with a continuous revolution counter and well mounted.

(b) The belts furnished will be 5 and 6-inch rubber belts 80 ft. long, and 7 and 8-inch rubber belts in 100-ft. lengths, and will be furnished by the committee.

Rule 7—Altitude and Temperature—All results will be reduced to a basis of 14.7 lb. barometric pressure. All results will also be corrected to atmospheric temperature of 70 deg. F.

Rule 8—Rating—The rating recommended for the tractor will be based upon the results of this test; 90 per cent of the horsepower developed throughout the test will be the recommended A. S. A. E. rating.

Rule 9—Re-entry—If an entrant is disqualified for any reason, he may apply for another trial. Such request must be made immediately.

Note—Any necessary interpretation of all rules will be made by the committee in charge of the test.

BRAKE DATA

Place of test .... Date...........
Name and model of tractor.............. Serial No.......
Fuel: Gasoline ....; Kerosene.................
Sp. gr. of fuel gas .... Kerosene.................
R.p.m. of belt pulley ....Pulley diameter.......
Pulley Face..........
Brake horsepower sustained ....
A. S. A. E. recommended belt rating (90 per cent of 2-hr. max.) ....

.... Data

Rules for Plowing Tests

Rule 1—Assignments—The company's representative should report for assignment to the committee in charge of tests upon the arrival at the ground. (Note instruction 3-B.)

Manufacturers must have tractors ready at the time assigned them or forfeit the privilege to that test.

Rule 2—Entries—(a) Only one tractor of each model of the same make may be entered.

(b) All tractors entered for test to be stock machines as regularly sold.

(c) Each tractor should carry a prominent placard 20 in. in height and 30 in. in width. If other size is used, dimensions should be of similar proportions.

Rule 3—Duration and Time of Test—Duration of all economy plowing tests will be four hours. The time for the tests will be set by the committee and company representative when assignments are made.

Rule 4—Position on Fields—The entrant will draw for his position on the field. The plots will be numbered, and the number drawn entitles the entrant to the plot bearing that number.

Rule 5—The Field—All lands will be of uniform length, and the width will be determined and marked before the test.

The entrant will not be required to finish his land as a part of the test. Special care will be used in selecting the fields for tests that all conditions will be as nearly uniform as possible.

Rule 6—Draft Test—Two preliminary rounds will be made to adjust the outfit. In the third round the average draft will be recorded with a dynamometer, after which the test will start. Following the four-hour run, another dynamometer test will be made, and the average of the two will be taken as the draft during the economy test.

The draft as was shown by the dynamometer will be reduced to the actual resistance in the direction of the line of travel. The angle of the dynamometer unit will be determined with a suitable geniometer.

The drawbar horsepower will be based upon the draft as obtained above and the average rate of travel taken during the plowing period. A dynamometer record should be secured for the complete round.

Rule 7—Fuel—The test should be made only on one fuel. This will eliminate the necessity of including more than one fuel in the final results. The fuel level in the tanks will be measured just before starting the test, and at the end of the test the fuel used will be determined. (See instructions.) The fuels commonly used in the particular locality in which the test is held will be supplied the entrants from one source. The lowest type of fuel available for which the tractor is recommended by the manufacturer should be used in the test.

Rule 8—Water—The water used in the radiators will be measured by the same method as used in measuring the fuel. If water is used in air washer or with fuel, it will be kept separate from the water used in the cooling system.

Rule 9—Travel—The rate of travel should be within 10 per cent of the speed at which the tractor is entered. This speed is to be maintained throughout the test.

Rule 10—Plows—The same plows with the same hitch and adjustments are to be used throughout the test, and no one will be allowed to handle or adjust the plow other than the operator of the outfit.

Rule 11—Depth—The depth is to be checked every 10 rods by the A. S. A. E. (Heylman) depth gage.

Rule 12—Width—The width cut by the plows should be checked at least every other time the depth is taken, and the operator should be made to maintain a uniform width of cut.

Rule 13—Delays—If it is found necessary to stop the tractor due to tractor trouble more than 30 min. in the aggregate the test is annulled.

Rule 14—Re-entry—If an entrant is disqualified for any reason, he may apply for another trial. Such request must be made immediately.

Rule 15—Data—All data will be the property of the individual manufacturers and of the test committee of the A. S. A. E. and it will be made public, unless the manufacturers desire to withdraw the results, and then no part of such data may be issued later. No partial data from any one test may be used as A. S. A. E. data unless the entire results of that particular test are published.

Note—Any breach of rules disqualifies the entrant. Interpretation of all rules and questions not covered by the rules shall be made by the committee in charge of test. (See instructions which cover and form part of these rules.)

Instructions for Conducting Tractor Plowing Tests

1B—Each company should place one man in charge of its interests in the tests who will consult with the test committee for assignments not later than one day before the time of the first test. The time for the tests and position in the field will then be assigned. Entrant must have his machine in the field ready to start the test at the time allotted, or forfeit the privilege to that particular test.

2B—(a) Only one tractor of each model of the same make may be entered for the same test. (b) All tractors entered for the tests must be stock machines as regularly furnished the trade. No special attachments or accessories will be used that are not regularly furnished with the machine. (c) Each tractor should carry a placard giving the following information:

Name .... Rating..........
No. of cylinders .... Bore......... Stroke...........
Normal Engine r.p.m. .... Travel..........M.P.H.
Travel..........M.P.H.
Travel..........M.P.H.
Fuel ....

The rate of travel at which the tractor is entered in the demonstration should be given in bold figures in the upper space; the other speeds, if tractor has more than one speed, in small figures in the lower space.

3B—To get any reliable and comparable data, it is necessary to have the tests of the same length. Experience has demonstrated that short tests are seldom satisfactory and results have little meaning to the practical man, hence tests of four hours are recommended. The time for the tests will be arranged by the company representative and the committee at the time of assignment.

4B—The entrant will draw for his position in the field at the time assignment is made. The plots will be numbered and the number drawn entitles him to the plot bearing that number. Special care will be used in selecting the fields for tests so that all conditions will be as nearly uniform as possible.

5B—The land will be laid out with headlands of sufficient width for turning and all lands will be within 10 per cent of the same length. This is done in order to place all tractors as nearly as possible on the same basis.

Stakes will be set up at both ends to indicate the starting line and the entrant may place as many intermediate stakes as he desires. He will be required to make a straight furrow in starting out and should maintain an even width throughout the test.

6B—Two preliminary rounds will be made to adjust the outfit. The dynamometer will be used the third round and the average draft will be recorded. Following the outfit on the third round, the observer will place at intervals of ten rods small stakes to mark the inner edge of the furrow bottom.

A link of equal length to the dynamometer unit will be placed between the plow hitch and tractor draw bar so the plow adjustment will not be disturbed when the dynamometer is used.

At the end of the third round, the dynamometer will be disconnected, the fuel measured, and the test started. The final

Air Development

EVERY support should be given to the attempt of the Army Air Service to develop aviation in the United States by its proposed plan to establish landing fields in thirty-two important cities reaching from coast to coast.

It is argued that the military authorities cannot have a commercial viewpoint and will build fields chiefly from a military conception, and that this may harm commercial aviation rather than further it; but any steps that will awaken public interest and recognition of commercial aviation are important, and there are no other government departments at this time that can do so much as the Air Service.

The only other department is the Post Office, which has not the power necessary for large development of commercial air routes and which lacks the initiative of the Air Service.

The Air Service probably will establish fields that are not logical for commercial usage, and even in some instances, after awakening public interest and expenditure of public funds, cause some revulsion of feeling by more or less impractical work; but this will be better than to allow aviation completely to revert to its pre-war state and require a long, slow process of evolution.

This matter of the control and regulation of aviation is one that should receive early consideration by the next Congress. There should be a department of aeronautics to control aviation under charge of a cabinet member so that the problems may be handled by one organization, which will make for consistent decisions.

Exchange and Credit

THE American manufacturers who are entering the export business are confronted with many extraordinary conditions. Not the least of these is the credit situation—always a matter for serious consideration in foreign trade.

The present complication of that situation is the high rate of exchange. This is one of the results of the long war period and the general upset of financial conditions. Foreign buyers naturally do not like to pay for their goods at the present rate of exchange. Most of the buyers in other countries feel that the rate of exchange will be adjusted within the year and that when this adjustment is brought about they would be burdened with merchandise paid for under the abnormal rate, which would be an important factor in computing their profits.

Bankers who have followed the exporting trade for years are suggesting that under present circumstances unusual credit extended the reliable firms would be a strong inducement to them to place large orders. If the credit were made 9 months or a year, the customer would feel that the exchange rate adjustment would come within that time and that he were on the same basis as firms that might buy later. This phase of the credit situation is presented without relation to other credit reasons or practices.

A successful exporter of lumber to South American countries was asked some months ago how he had succeeded where so many had failed. He answered: "I have always tried to adjust my collections to low exchange periods. A South American merchant greatly appreciates an extension when exchange is high, and most of my customers shorten their credit period of their own accord if exchange drops to a low figure. Especially is this true since they have learned that I make every effort to adjust my end of the credit to the exchange rate. Before the war my customers were shortening credits about equal to the extensions I granted."

At the time of this conversation the present situation did not obtain, but the practice mentioned was developed merely as a "good business policy." Foreign merchants, especially those in Latin America, respond to such favors.

Tractor Demonstration Rules

THE publishing of tractor demonstration rules by the American Society of Agricultural Engineers, and also the publication of the rules governing the British Tractor Demonstrations for this year, suggest the prime importance of tractor demonstrations which shall furnish data that are of use not only to manufacturers but to the entire tractor industry.

Heretofore American tractor demonstrations have been practically useless and valueless from an educational point of view. The national tractor demonstrations have been mere exhibitions of plowing and tilling.

The agricultural engineers are to be congratulated on drafting what is known as their Class A rules, which are good, but do not go far enough. In some instances these rules check up sufficiently well with the British rules to give them an international significance; but in other respects the British rules are more embracing and will furnish more educative data.

The American and British rules agree in plowing demonstrations extending over a number of hours. The British insist on 5 hours plowing per day, whereas the A. S. A. E. (American Society of Agricultural Engineers) rules call for 4 hours plowing per day. Either is immeasurably superior to 2 and sometimes 3 hours of plowing, as has been the custom heretofore at national demonstrations.

If space is available, there should be plowing from 8 o'clock in the morning until 6 in the evening. This would give a clue as to the strain of the tractor on the operator, which is a very important matter, and one not considered by any existing rules.

The British tractor rules require an observer to attend each tractor throughout its performance and in this respect are superior to the American rules. The object of the observer is not only to secure an indisputable report on the tractor performance and tractor stops, thus providing valuable data, but also to insure fair rulings in every possible way.

The British rules are commendable in that they allow 1 hour for refilling tanks, oiling, and repairing each day. The repairing, if done by the operator, does not result in penalty to the machine, but if outside assistance is needed the tractor is penalized on a man-minute basis, the assumption being that additional help costs the farmer money, and in an official demonstration made for commercial purposes only, such added cost should count against the score of the tractor.

The practice of letting the tractor be taken at night to the headquarters of the manufacturer where it can be repaired, adjusted, or refitted, as necessary, is not permitted under the British rules, the assumption being that the public has a right to be told the entire story of what has had to be done to the tractor during the demonstration. This is sound logic.

It is scarcely ethical to publish a fifty report when it really should be a fifty-fifty one. If we tell the exact performance of the tractor, we should also tell the work that must be done on the tractor during the demonstration to make this performance possible.

Tractor accessibility is not sufficiently recognized in either the American or British rules. Under the British regulations it may come to the surface in that repairs only be made in the 1 hour; and under the American rules, the provision is that the tractor is disqualified if more than 30 min. are needed for tractor troubles during the test. We do not think a 30-min. period is a fair test. No piece of machinery is perfect, and picking out an arbitrary time limit, which, if exceeded, results in disqualification, is a dangerous policy to follow. Why not follow the British policy of penalizing on a man-minute basis?

One commendable feature in the British rules is that limiting the warming up or starting period of the engine for 10 min. The farmer has learned that whether gasoline or kerosene is used in warming up the engine or in plowing, the net result on his pocketbook is the same.

The question of arranging blanket speed rules for plowing, and requiring that a tractor must plow within 10 per cent of its rated speed, is a difficult task. It is one thing to plow at a rated speed on the 320-acre field of Kansas, and another thing to plow at the same speed on hilly ground in Pennsylvania, where there is a goodly proportion of stones.

It will not be possible successfully to use the A. S. A. E. rules in all states in the Union and have the same speed regulations, as demonstrated in many of the tractor trials last year.

The Class B, A. S. A. E. rules as they are officially known, are recommended for demonstrations by manufacturers, distributers, dealers, agricultural institutions, and county agricultural agents. They do not place any time limit on the demonstrations outside of the 4-hour plowing period. It is hoped that the demonstrations will at least occupy 2 days.

Latest News of the

Revised Tax Rulings Issued

Treasury Dept. Makes Changes as Result of Protests of N.A.C.C., N.A.D.A. and Other Associations

WASHINGTON, June 2—As a result of numerous protests from the National Automobile Chamber of Commerce and the National Automobile Dealers' Association and other bodies, the Treasury Department has issued new rulings relating to some of the excise taxes on cars, trucks and parts. The tax on tires, accessories and parts does not apply when sold to the manufacturer or producer of passenger cars, trucks or motorcycles for the sole purpose of being used in their manufacture or for sale as a part of the manufactured product. In all such sales, however, it will be necessary for the purchaser to furnish a certificate showing that the parts or tires will be used as prescribed.

The ruling on chassis, whereby all chassis were classed as passenger cars and taxable at 5 per cent, has been changed, and any chassis with a superstructure that will allow its use as a truck without any substantial additions is regarded as a truck and taxable at 3 per cent. All other chassis, however, remain taxable at 5 per cent.

Under the original regulations a manufacturer, who is also engaged in retail business, was allowed to base his tax on the average monthly wholesale price. Under the new regulations, where it is impracticable to follow this plan, the taxpayer can base his tax on the ordinary regular wholesale price for which like articles were sold in the month previous.

When tires are returned for replacement, due to the fact that they have not traveled the guaranteed number of miles, a tax on the replacement is figured on the actual price of the transaction.

Following is the complete amendment:

EXCHANGES PURSUANT TO GUARANTY.

Where any article taxable under Section 900 is returned to the manufacturer thereof, for adjustment, replacement, or exchange, under a guaranty as to quality or service, and a new article given pursuant to a guaranty, free or at a reduced price, the tax shall be computed on the actual price, if any, to be paid to the manufacturer for the new article.

Article 14 of Regulations No. 47, entitled "Tires, inner tubes, parts, and accessories sold to manufacturer" is hereby modified to read as follows:

"Subdivision (3) Section 900 of the Act exempts from tax sales of tires, inner tubes, parts, or accessories to a manufacturer or producer of automobile trucks, automobile wagons, other automobiles, motorcycles, tires, inner tubes, parts, or accessories. To come within the exemption the sale must be to such a manufacturer for use by him in the manufacture or production of automobile trucks, automobile wagons, other automobiles, motorcycles, tires, inner tubes, parts, or accessories or for sale by him on automobile trucks, automobile wagons, other automobiles, or motorcycles or in connection therewith or with the sale thereof or for free replacement under contract or guaranty. If sold to such a manufacturer for any other purpose, such as resale to a dealer or for the rebuilding of used cars, the sale is taxable. In order for the sale to come within the exemption of the statute, the manufacturer must at the time the goods are shipped or sold (whichever is prior) have in his pos-

Work on Wills-Lee Plant Starts

Expected to Be in Operation by Fall—Design of New Car to Be Announced Soon

DETROIT, June 3—Work will start at once on the first three units of the automobile plant to be built here by C. Harold Wills and John R. Lee, former Ford executives. The units will each have a length of 1000 ft. Construction plans will be rushed and it is hoped to have a complete plant in operation by fall.

It is expected that the new organization will announce the design of its new car within the next 60 days. Reports are that the machine will sell at between $1,200 and $2,000, and will be a light 6-cylinder machine, embodying many new features in body and engine design. Mr. Wills has been working on the car for several years and he states that experimental machines have been driven as much as 180,000 miles.

It is said that many of the ideas of the Hispano-Suiza car have been adopted by Mr. Wills and that he controls a number of the American patents on the French car. It is also rumored that the new Wills engine is exceptionally light, and that it is air cooled.

The construction of a self-contained factory, as outlined by the promoters, will entail an investment of millions. There are many who believe that Henry Ford is directly interested in the new enterprise, although this is doubtful. Both Wills and Lee have been close to Ford, having left that organization but a few months ago.

In Port Huron it is reported that Wills and Lee have invested $1,000,000 in the 2000-acre factory site. A big portion of this site they have purchased outright and have taken options on the rest of the land, which is located on the St. Clair river three miles below the city.

John R. Lee has purchased a residence in Port Huron and will move there at once to superintend the construction work.

German War Trucks Are Brought Here

Col. Slade of Armistice Commission Has 47 Surrendered Vehicles at Baltimore

NEW YORK CITY, June 2—Lieut. Col. A. J. Slade of New York City, who was a member of the Permanent International Armistice Commission with headquarters at Spa, has returned to America and expects to be discharged within a few weeks. Col. Slade, who, previous to going to France, was in engineering work, was the representative of the A. E. F. Motor Transport Corps on the Armistice Commission. He had to do with making definite arrangements for the handing over of the 5000 German trucks, 1250 of which were turned over to the Americans. These 1250 were placed in parks and over 300 of them immediately put into reconstruction work. All were fitted with steel tires. Col. Slade selected types of the principal makes and had a very complete technical report of them prepared. He has brought 47 of these trucks to America and they are at Baltimore, where they are awaiting complete technical inspection by a committee appointed by the Motor Transport Corps.

Driver's Cab a Feature

In fitting these trucks with steel tires the speeds were cut down to approximately 8 m.p.h. and improvements made in the spring suspension. The use of supplementary spiral springs is very general in them. Many of the trucks are fitted with narrow dual steel tires. A characteristic of these German trucks, and one in which they greatly surpass American trucks, is the cab equipment for the driver. On all makes this is particularly complete.

In general the trucks are of the 4-cylinder type, a few of these using block castings, but the majority with twin castings. Valve-in-the-head construction is used in a few cases. Cone clutches, 4-speed gearboxes, and chain drive are characteristic of practically all. The Germans gave more attention to frame construction than is general in American truck practice. The majority of the frames are bottle-neck pressed-steel designs.

F. W. HENNINGER DIES

DETROIT, June 3—Frederick W. Henninger, 46 years old, president of the Sheet Metal Stamping Co. and vice-president of the Bellevue Mfg. Co., died here Friday morning.

Automotive Industries

Overland Factory Shut After Riots

General Manager Earl, in Statement, Says Union Leaders Promoted Attacks

TOLEDO, OHIO, June 4—Rioting at the Willys-Overland plant last night which resulted in killing of two men and injury to scores of others caused the company to close down to-day, and it will remain closed for an indefinite period. A mob, several thousand strong, attacked loyal workers as they were leaving the factory last night.

Guards fired into the crowd and a fight followed.

Mayor Schreiber of Toledo declares the city is powerless to further protect the factory. He has appealed to Governor Cox for troops and it is expected that Toledo will be placed under martial law.

During the day there were three riots. Early street cars carrying loyal employees to the plant were attacked, windows smashed with bricks and passengers pulled into the street and beaten.

C. A. Earl, first vice-president and general manager of Willys-Overland, ordered the plant closed. Work was resumed a week ago after two weeks of idleness and, until the outburst yesterday, the situation was thought to be well in hand.

In a statement to AUTOMOTIVE INDUSTRIES, Mr. Earl charges union leaders with responsibility for rioting.

His statement follows: "The Overland plant will be closed to-day at the urgent request of the mayor, as a result of rioting. Toledo faces the most critical hour of her history. She is squarely face to face with the question:

"Shall American citizens, residents of Toledo, exercise their constitutional rights to earn an honest living, or shall violent, irresponsible thugs drive thousands of workers from their work, and dominate the city with brutal and murderous intimidation?

"The riots occurred at exits and entrances of the plant and at street car transfer points. Strikers even attacked the office building and its occupants. Last night many were injured and two were killed in an attack made in the home district of our Polish employees.

"These mob attacks have been credited by some newspapers to disorganized men and I. W. W. The public should know that men hiding behind these cowardly attacks on women and old men are leaders in the machinists and other unions, who, by their speeches and advice to the men, have stirred up and created this condition. The blood of the dead and injured men and this disgrace to Toledo are on their heads.

"The condition demands that we must go to the limit in doing what is required to meet the situation."

Gas Warfare Talk at S.A.E. Summer Meet

NEW YORK CITY, June 5—Gas Warfare will be the subject of the Wednesday evening lecture at the summer session of the S. A. E. at Ottawa Beach, June 25. J. Johnston, Professor of Chemistry at Yale University, who has had a great deal to do with the development of gases for war uses, will speak. This, coupled with the lecture on wireless telephony, with demonstrations on Tuesday evening, June 24, gives an importance to the summer sessions that has not been present in former years.

It is very probable that there will be an exhibit of German trucks which have been brought to America by the Motor Transport Corps, and which will be shipped to Ottawa Beach.

Commander J. C. Hunsaker will give an address on the progress of naval aircraft. Another paper added to the program is that by H. Heindlhofer on tests of truck axle and worm bearings.

Total reservations to date are 515.

325,000 TONS OF STEEL FOR G.M.C.

NEW YORK, June 5—The placing of an order for 325,000 tons of steel by General Motors Corp. has been confirmed by Judge Gary, chairman of the United States Steel Corp. This is one of the largest orders placed since the signing of the armistice, and the purchase is for the subsidiary companies of the G.M.C. The exact tonnage of various kinds of steel has not been announced. It is understood that the stabilization prices govern the sale.

It is said that Willys-Overland, Inc., has placed a large order for steel.

MAXWELL-CHALMERS PLANS

NEW YORK, June 5—A meeting was scheduled for to-day at which final details of the Maxwell-Chalmers merger plan were to be worked out, preliminary to the making of an announcement as to what these plans are. The postponement of the meeting will, however, delay the announcement, which it is now expected will be made within the next week.

WHITING OF BUICK IS DEAD

FLINT, June 3—J. H. Whiting, who brought the Buick Motor Car Co. to Flint, 16 years ago, died Monday morning in New York City.

1920 Show Dates Fixed by N.A.C.C.

New York Exhibit Jan. 3-10—Chicago, Jan. 24-31—Truck Shows Same Dates

NEW YORK, June 5—The New York Automobile Show will be held Jan. 3-10, 1920, in the Grand Central Palace. The Chicago show will be held Jan. 24-31 in the Coliseum.

Truck shows will be held in both cities on the same dates. The place of the New York show has not been decided upon, but the Chicago show will be held in the Drexel Pavilion, in the stockyard section. S. A. Miles will again be manager of both shows.

These dates were decided upon by the directors of the National Automobile Chamber of Commerce yesterday. The members of the N. A. C. C. met to-day and will decide upon details concerning the shows. C. C. Hanch, who has recently returned from Europe, addressed the members.

An export managers convention will be held to-morrow.

GAS ENGINE ASSN. MEETING

CHICAGO, June 3—The National Gas Engine Association, at to-day's session, adopted the new constitution permitting of sectional organization.

The following officers were elected for the ensuing year: President, L. A. Ward, Cushman Motor Co., Lincoln, Neb.; first vice-president, T. C. Menges, Associated Manufacturers Co., Waterloo, Iowa; second vice-president, Henry Kennedy, Lally Electric Light Corp., Detroit. The executive committee is composed of J. F. Richards, Alamo Farm Light Co., Hillsdale, Mich.; F. E. McKee, Manning, Maxwell & Moore, New York City; George Cormack, H. C. Dorman Co., Oshkosh, Wis., and the presidents of subsidiary sections, who automatically become members of the executive committee. H. R. Brate, secretary of the association for a number of years, handed in his resignation. The subsidiary sections will report on their organization later.

TRUCK AUCTION DELAYED

WASHINGTON, June 3—The War Department announces that delays incident to the inventorying of its stock of surplus motor equipment which has been found to be unsuitable for Government use, will necessitate a postponement until after June 15 of the public auctions of used passenger and commercial cars, which had been announced for June 1.

Michigan-Ohio Output Hit by Strikes

May Daily Production Fell 396 Cars Below April — Labor Trouble Responsible

DETROIT, June 2—Daily car production figures for Michigan and Ohio during the month of May follow:

Car	April	May
Buick	500	500
Briscoe	75	75
Barley	10	10
Cadillac	100	80
Chalmers	80	80
Chandler	60	70
Chevrolet	700	726
Columbia	18	20
Dodge	500	500
Dort	100	100
Ford	3000	3000
Harroun	15	15
Hudson	100	100
Hupp	75	60
King	10	10
Liberty	30	30
Maxwell	250	250
Olympian	10	12
Oldsmobile	140	150
Overland	600	200
Packard	25	25
Paige	70	75
Paterson	15	15
Jordan	12	15
Reo	125	125
Saxon	50	35
Scripps-Booth	45	50
Studebaker	200	150
Winton	10	10
Essex	100	100
Grant	50	50
	7084	6688

Car production in Michigan and Ohio during May was hard hit by labor trouble, statistics revealing a falling off in the daily production of many factories. During the month daily production averaged 6688 cars as compared with 7084 produced daily during April. Strikes in the plants of parts makers were largely responsible for the subnormal production, although in the cases of Willys-Overland and Studebaker No. 3 factory, Detroit, the strikers effectively tied up manufacturing work.

Saxon and Hupp Also Affected

Saxon, Hupp and others were hit by the Wilson Body Co. strike, which curtailed the supply of bodies. The walkout at Timken-Detroit Axle Co. hampered Cadillac and one or two other companies, and the Salisbury Wheel & Axle Co., Inc., strike at Jamestown, N. Y., if it develops seriously, is threatening Paige production. The Willys-Overland Co., which was running 600 cars daily at the time of its strike, has not produced a car in three weeks. Studebaker production was affected by a walkout, but to just what extent is not known at this time.

All of the car makers are oversold, some of the companies, as the Jordan Co., Cleveland, having sold its entire production for the next eight months.

75 PAIGES A DAY

DETROIT, June 2—May production at the Paige-Detroit Motor Car Co. averaged approximately 75 cars daily. The high mark was 110 machines in one day and the low mark 40 completed cars. The plant's normal capacity is 100 machines daily, but this figure will not be reached before August. The company has orders for five times more cars than can be produced.

JORDAN MAKES 15 A DAY

CLEVELAND, June 2—The Jordan Motor Car Co. has run up its production to 15 cars daily, with its entire output for the next eight months sold in advance. The company will produce 4000 cars this year and hopes to have its new factory in operation by July 15. Work on the new plant is now under way.

1020 SCRIPPS-BOOTHS IN APRIL

DETROIT, June 2—The Scripps-Booth Motor Car Co. produced 1020 cars last month, working on a basis of 22 days to the month.

500 BUICKS A DAY

FLINT, MICH., May 28—The Buick Motor Co. is not yet back in normal production. The plant is turning out between 450 and 500 cars daily. While some difficulty has been experienced in getting certain parts, this situation is rapidly clearing up.

ROAMER ORDERS

KALAMAZOO, MICH., June 2—The Barley Motor Car Co., maker of the Roamer, is 500 orders ahead of production. The company is running between 6 and 10 cars daily, but is having some trouble getting a steady supply of bodies. The plant is now employing approximately 200 men.

15 OLYMPIANS DAILY

PONTIAC, MICH., June 3—The Olympian Motor Car Co. is producing 12 cars daily and is preparing to increase this production to 15 cars at once.

FEDERAL TRUCK PRODUCTION

DETROIT, June 2—The Federal Motor Truck Co. is running 20 trucks daily and has business on its books in excess of production.

AUTO BODY SCHEDULE

LANSING, MICH., June 2—The Auto Body Co. has just closed contracts for new business, which with other orders on hand, will fill the working schedule for more than 6 months. Orders are from the Olds Motor Works, the Reo Motor Car Co., Briscoe Motor Corp. and the Auburn Automobile Co.

Fewer Strikes in the Detroit Field

Nearly All Trouble Cleared Up and Men Back at Work—Ford Plants Threatened with Walkout

DETROIT, May 31—Automotive labor difficulties in Detroit are clearing away. The number of strikes is much reduced, the only ones being among tailors, butchers, box makers, etc.

The Liberty Starter Co.'s trouble is being rapidly eliminated. Of 700 men who originally walked out of this plant, 50 per cent are now back on the job.

The Timken-Detroit Axle Co. has several hundred men out. Several departments have been effectively closed. The company is operating, although its production has been greatly curtailed.

Malleable Iron at Standstill

The Michigan Malleable Iron Works and moulders are still in deadlock. Approximately 150 men are idle and the company is unable to get into production.

The Wadsworth Mfg. Co. is operating in spite of the strike which has been on there for 3 weeks. The output of Ford sedan bodies has been badly cut, but the new $6 minimum wage scale inaugurated by Wadsworth has proved an inducement which has brought hundreds of the striking employees back. This plant is still being picketed by the union, which claims that nearly 1000 men are still out.

The strike at the Aluminum Castings Co. has dwindled down to a minor affair. There are less than 200 men out, and dozens are returning daily.

The Commonwealth Brass Co. is closed tight because of a strike. Approximately 200 men are out.

The L. A. Young Industries Co. has about reached an agreement with its workers, 800 of whom quit their jobs 2 weeks ago. Nearly one-half of the strikers are back and others are returning daily.

Union Threatens Ford Plants

The United Automobile Vehicle and Aircraft Workers of America, which called the strike at the Wadsworth plant, are bending every effort to bring about a general walkout at the Ford Motor Co. and Fordson tractor plants. When the Wadsworth plant was closed by the strike Ford rushed hundreds of his men into that establishment to prevent the stopping of his supply of sedan bodies. These men were brought in under guard on army motor trucks. With the assistance of Ford, Wadsworth has been able to keep up a fair production, much to the chagrin of the outlaw union.

The Studebaker Corp. had a walkout at the No. 3 Detroit plant yesterday, several hundred men quitting. The trouble resulted from the expulsion of four foremen. The men now refuse to return to their jobs unless granted a substantial wage increase and shorter hours.

Novel Conditions for British Tractor Trials in September

Each Machine Will Be Rated by Dynamometer Before Listed for Entry at Society of Motor Manufacturers and Traders, Ltd.—Plowing Tests at Lincoln

LONDON, May 15—British tractor trials will be held at Lincoln, England, during September, 1919, by the Society of Motor Manufacturers and Traders, Ltd., which is the national automobile organization of Great Britain. It was expected that the Royal Agricultural Society of England would hold tractor demonstrations this year, but this society seemed to think that 18 months were necessary for the tractor manufacturers to recuperate from the war, and it will not hold tractor demonstrations until the fall of 1920.

The trials to be held next September are typically British in their searching character. They are not to be merely a demonstration, but will be a thorough test of the machine as well. For example, on the first day there will be plowing on heavy soil from 10 a.m. to 5 p.m., with an hour interval at lunch. On the second day there will be a similar program of plowing on light soil. On the third day there will be 2 hours plowing in the morning and 3 hours of cultivating land previously plowed in the afternoon.

Previous to the plowing, there will be a draw-bar dynamometer test for the purpose of guiding the entrants as to how many plows they can handle and also to ascertain the pulling capacity of the tractor. The tractors will be fitted with a recording dynamometer and readings taken at a speed of 2.5 m.p.h.

The total gear ratio on each gear, the driving wheel diameter in the case of wheeled vehicles, or the pitch diameter and pitch of the track sprockets in case of a track or creeper type machine must be declared and marked on the sign carried on the tractor.

During the plowing work an observer will accompany each machine and completely report on everything connected with its work.

At the end of each day the tractors will be parked, but no repairs, renewals, or adjustments will be made on them during the night, except by special arrangement with the judges. Any necessary adjustments must be made during the period of one hour immediately previous to the start of work in the morning.

Only 10 minutes will be allowed for warming up engines before the plowing starts. In case of steam tractors 30 minutes is allowed.

The judges of the trials will take into consideration the following factors in making their awards on the machines:

a—Weight of machine in full working order with spuds
b—Weight per sq. ft. on front and back wheels separately in the case of a wheeled machine, or with per sq. ft. of track in contact with the ground for a track machine, in each case calculated on a sinkage of 1 in. only
c—Cost of fuel and lubricating oils per acre, in proportion to the draw-bar pull
d—Water evaporated per acre
e—Ease of handling, including starting time and turning at headlands
f—Reliability (freedom from mechanical troubles)
g—Capital cost in relation to draw-bar pull in lbs.
h—Mechanical construction, having special regard to simplicity and access to wearing parts.
i—Safety of operation.
k—Number of attendants
l—Suitability for haulage and threshing purposes as shown by construction
m—Efficiency of adhesion
n—Working cost per acre
o—Capacity in acres per day of 8 hr.

Implements will be judged on the basis of:

a—Construction and operation
b—Adaptability for different widths and depths of plowing or cultivating
c—Quality of work done

It is the spirit of the rules that during the hour given each morning for refilling with fuel and making necessary repairs, that the operator or operators are the only ones who can work on the machine without penalty. If further assistance is required, the tractor on which such work is done will be penalized by recording the number of man-minutes for assistants so employed.

One grade each of gasoline, benzol and kerosene will be furnished. No cooling medium other than water is permitted.

Entries may be made by the British importer or the American manufacturer. Many entries have already been received and more than 50 different makes are expected.

Although the performance of implements is to be judged, entries of implements are not being taken. Plow and other implement manufacturers should get in touch with tractor makers if they wish their implements represented.

COALITION MEETING

NEW YORK, June 3—The Material Handling Machinery Manufacturers Association will hold a coalition meeting of all manufacturers of mechanical handling machinery and equipment and accessories in the United States, at the Hotel Astor, June 11, morning, afternoon and evening. This includes all manufacturers of cranes, winches and hoists; elevators; gravity and power conveying machinery and apparatus; industrial trucks, tractors and trailers; bulk handling machinery; and all makers of equipment and accessories such as storage batteries, bearings, ropes for hoists, buckets, electric controllers and apparatus, etc. Advertising managers of companies manufacturing these products will hold a preliminary conference at the Hotel Astor, June 10, at 8 p. m., at which time it is planned to form an advertising council of the M. H. M. M.

Among the speakers for the day meeting are: James H. Collins, special writer of business articles, and Francis Holley, director of the Bureau of Commercial Economics. A general Forum discussion will be conducted in the afternoon and a mass meeting is planned for the evening, at which addresses will be made by Hon. Theodore Burton, former U. S. Senator, and Murray Hulbert, Commissioner of Docks, New York.

GOODRICH INCREASES MILEAGE

NEW YORK, June 2—The B. F. Goodrich Rubber Co. has revised its adjustment schedules on both fabric and cord tires. Effective at once, fabric tires are to be guaranteed 6000 miles instead of 3500, and cord tires 8000 instead of 5000 miles. Goodrich tires already in the hands of purchasers, no matter when they were purchased, will be adjusted under the new mileage guarantee.

DECREASE IN AIR TRAINING

WASHINGTON, June 2—A decrease in the number of hours flown at training fields in this country is shown in a report by the Air Service. A total of 10,135 hours were flown in the week ended May 15, 1919, as compared with 23,943 for the week ended Nov. 11, 1918. The total attendance at training schools has decreased from 5099 on Nov. 11, 1918, to 294 on May 15, 1919.

The flying fatality rate has increased since the signing of the armistice. The rate now is one fatality to every 1467 hours flown as against one to every 3149 prioi to the armistice.

The table shows the attendance at training schools and fatality rate.

Attendance	Elementary Schools	Advanced Schools.	Total
Nov. 11	2,423	2,676	5099
May 15	276	18	294
Graduations			
Nov. 11	208	96	304
May 15	155	..	155
Hours Flown at Flying Fields			**Hours Flown**
Week ended Nov. 11			23,493
Week ended May 15			10.135
Period		**Fatalities**	**Hours Flown per Fatality**
June 1 to Nov. 11		156	3,149
Nov. 11 to May 1		71	1,467

The serious accident rate (exclusive of fatalities) reflects a similar tendency.

Period	Serious Accidents	Hours Flown per Serious Accident
June 1 to Nov. 11	169	2,907
Nov. 11 to May 1	71	1,467

Citroen Stirs Up French Industry

Announcement of Low-Priced Car Perturbs Other Manufacturers —His Successful Advertising

PARIS, FRANCE, May 5—Automobile France is still perturbed over the activities of André Citroen, the automobile manufacturer, who, following the war, announced the turning over of his enormous munitions factory in Paris to the manufacture of a cheap car, of which he prepared to produce 100 per day.

The Citroen car, described some time ago in AUTOMOTIVE INDUSTRIES, is the nearest approach of any French manufacturer to a Ford, but the Citroen does not quite measure up to Ford capacity. It is a satisfactory light car for two passengers, but general sentiment is that it is not suitable as a 4-seated car.

There is no denying the fact that Citroen has had a very marked influence on the automobile industry in France. One example is that of advertising. Up to the time of the war, French car manufacturers did not understand the elements of advertising. The little money they expended was practically wasted, and some of the largest firms placed their advertising in the hands of men who were no better qualified than stenographers in advertising experience.

When Citroen came out with his large advertising program he got away from the narrow old French view of advertising. This advertising made a strong appeal and Citroen has been able to get in heavy deposits at the rate of 1000 francs or $250 per car. This is a particularly heavy deposit, when the reported profit that a dealer makes from the sale of a car is 650 francs or $130.

The French automobile industry, which must be looked upon as a very close body, resented Citroen's activities. The old firms were thoroughly stirred up by his activities. The reports that Citroen was not given space at the Lyons Fair can scarcely be credited, as his name appeared on the official list. He did not exhibit in one of the Fair spaces, however, but secured a corner store immediately opposite to the automobile section of the Fair. His exhibit was always well attended, as were practically all of the other car exhibits.

TRUST CONTROL IN ENGLAND

LONDON, May 16—The Committee on Trusts, appointed by the British Minister of Reconstruction in February, 1918, has prepared its report on the action it considers necessary in view of the probable growth of trade organizations and combinations. The report has not yet been published, but the American Chamber of Commerce in London understands that the chief recommendation is that the Board of Trade should establish tribunals for investigating the operations of monopolies, combines and trusts, and then report to the government for action to remedy any abuse. All members of the committee are believed to have signed the report, but three members have submitted an addendum expressing the opinion that the recommendations are insufficient.

Their view is that capitalistic combination influences the price of practically every commodity sold to the public. They recommend, therefore, that the Board of Trade should establish a Trusts and Combinations Department to draw up a program to protect the community against the evils of monopolies and to secure economic benefits resulting from better industrial organization.

British Import Rules Penalize the Consumer

LONDON, ENGLAND, May 13—The prospects are that the duty on automobiles imported into England after Sept. 1, 1919, will remain at 33⅓ per cent, and that restriction of imports such as exist to-day will be entirely removed. Nothing definite on this will be known until after Aug. 1. In the meantime the British situation is unsatisfactory to practically everyone. There are almost no deliveries of British cars and consequently the consumer is penalized, and the British dealers, no longer having their various forms of war work, are worse off financially to-day than they were during the war. The new preferential tariff will permit import of Canadian cars at 22 per cent after Sept. 1, 1919.

British manufacturers have been amazingly slow in getting into production, and many of the biggest firms have not yet delivered a single car to the public, and in some cases they have not delivered a demonstrating car to their dealers.

The rationing scheme for British importers whereby they obtain from April 1 to Sept. 1 50 per cent of the 1913 imports is not proving satisfactory. This scheme is generally considered unfair, because the government did not take the pre-war year, that is the 12 months ending July 31, 1914, but the earlier period, namely, the calendar year of 1913. There was no apparent reason for this action except that it enabled the government to handicap the importer a little more and restrict his activities.

The Olympia Motor Show in November is going to mark the real start of the British industry after the war. There will also be a Scottish national show at Glasgow in January, 1920. Add to this the tractor trials to be held in September, and the exhibition of commercial vehicles in the spring of 1920, and also the aero exposition in the spring of 1920, and you have enough indications that beginning with Nov. 1 the British should be fairly well under way.

CHANDLER INCREASES DIVIDEND

CLEVELAND, June 3—The Chandler Motor Car Co. will increase its dividend from $12 to $16 per share per annum, and has declared a regular $4 quarterly dividend.

New Zealand Dealer on Foreign Situation

Clarkson Gives European Car Makers Two Years to Get Back to Normal—Demand Heavy

NEW YORK, June 2—J. B. Clarkson, one of the largest operators in motor cars, accessories, and motor apparatus in general, in New Zealand, arrived in America last week on his annual visit. Mr. Clarkson came from England, where he spent much time studying the industry. He is of the opinion that it will be at least two years before the European automobile organization is at its full 100 per cent effort.

The delay of European organizations getting into full production is, according to Mr. Clarkson, largely the result of the 4½ years of war. The reaction has made itself felt for many months and is still making its impression. The factory workers thought of nothing but the war from 1914 up to Armistice Day, just as the troops did, and there is a spirit of unrest that will not disappear for some time.

Mr. Clarkson is one of the directors and handles De Dion cars in practically all parts of the world outside of France and America. There are probabilities that the manufacture of De Dion cars will be taken up outside of France.

The car demand in New Zealand is found to be exceptionally heavy because the country has not been obtaining all the cars necessary during the war, and much money has been made from wool, meats, dairy products, etc.

The New Zealand business is entirely independent and not connected with Australia, as is so often imagined. New Zealand approximates 1000 miles, or a 5-day boat trip from Australia. Wellington, in the North Island, and Christchurch, in the South Island, are the major distributing centers, and Mr. Clarkson has large interests in both cities.

TIRES FOR GREAT BRITAIN

WASHINGTON, May 31—Rubber tires can now be exported to Great Britain on a basis of 50 per cent of the 1913 importations. The shipments will be rationed by the British government.

F. W. D. IN CANADA

CLINTONVILLE, WIS., June 2—J. D. Cotton will be president of the new corporation just formed to take care of the F. W. D. truck production in Canada as a branch of the Four Wheel Drive Auto Co. of this city. Henry Nyberg is vice-president and sales manager; Archie Kerr is secretary, and W. G. Cleghorn treasurer. The officers, with E. C. Kahel, W. T. Barrie and H. J. Sims, form the board of directors. Of the $200,000 capitalization, $100,000 of the stock is held by the Wisconsin company.

A site is to be selected and building operations commenced immediately on a structure 200 x 120 ft.

"Sufficient Fast Ships" Is Hurley's Promise to Pan-American Conference

Chairman of Shipping Board Says New York-Buenos Aires Time Will Be Cut from 24 to 15 Days—Other Speakers Tell of Use to Be Made of Capital

WASHINGTON, June 4—It is necessary for the stability of the trade in South and Central America to send not only salesmen but American intelligence and American capital into every Latin American country. Traveling salesmanship, as practiced in the past, will not suffice.

This will mean a complete revolution in the present and past methods of our doing business, but it will also mean a stable and permanent prosperous trade between the United States and its sister republics on the American continents. These principles are the keynotes of the discussions at the Pan-American conference which is being held here this week.

Every speaker from the Latin American countries dwelt upon the need of the investment of American capital and American intelligence in these countries, and Secretary of Commerce Redfield pointed out specifically, and in great detail, that American manufacturers must prepare for this permanent method of establishing trade if they went to maintain and develop the foothold gained in the last 4 years.

America has in 4 years become a creditor nation. Four years ago it was obliged to use the ships, insurance companies and banking facilities of its European competitors. It was a debtor nation. To-day it has ships, banking facilities, trade news sources, and has become the creditor nation of the world. It need no longer gain its trade news through competitors and allow them the opportunity of using the information thus acquired. Its financial turn from a nation with debts totaling $5,000,000,000 to a nation with credits of more than $12,000,000,000 has created a different situation which calls for different methods of foreign trade.

Brazil, which exported $119,000,000 worth of wool to the United States in 1918, has exported but $8,000,000 worth in the first 4 months of 1919; $22,000,000 worth of hides exported in 1918 has decreased to $4,000,000 in the first 4 months of 1919. This indicates that the trade between Latin America and the United States which, in 1918, was exports from the United States amounting to $685,941,239 and imports from South America to the United States totaling $1,105,274,492, will this year result in a reverse balance and means that Latin America will not have the cash to pay for her merchandise. This means further that if we increase the trade balance unfavorably to the Latin American countries by increasing shipments from this country, we must find some method by which Latin America can pay its bills. And, stated Secretary Redfield and all of the representatives of the Latin-American countries, the only way by which payment can be made will be through the investment of American capital in South America in the construction of highways, railroads, factories, petroleum industries and the purchase of Latin American securities.

By this means American commerce will secure three-fold results:

1—It will have a direct return to the United States of profits accruing from the investments.

2—It will have a flow of foreign trade to the United States as the result of the increased prosperity created in the Latin American countries by American capital.

3—It will have a development of wealth in Latin America which in turn will increase the buying power per capita in those countries.

Similarly the investment of American capital in Central and South America will mean to the Latin American countries the development of new lands, of new resources, the discovery of new riches, efficient economic organization and the employment of labor.

In making their investments, however, American manufacturers were urged by the Latin American speakers and Secretary Redfield to devote their capital honestly.

"There must come into our mutual trade," said the Secretary, "the spirit of service. Unless we serve you we shall fail; unless you serve us you will fail. The United States is now suffering from an overdose of prosperity. We have a huge reserve of gold behind our currency and in every element of economic power stand at the very height of prosperity.

"Because we are creditors on an enormous scale we must help those who owe to pay us what they owe and out of this problem comes the constructive type of foreign trade which offers the only solution to it. Our constructive service calls on us to let this capital flow out into the world for the world's enrichment. There will come inevitably to the United States rewards from such use of its wealth abroad. There will come, I hope, to the lands in which that wealth is used far greater rewards than can come to us."

Assurance that a fast and sufficient merchant marine will ply between the North and South American continents was given by Edward N. Hurley, Chairman of the United States Shipping Board. His statement, which is regarded as highly important because shipping transportation is considered of almost as equal importance as financial investment abroad, met with considerable applause.

Mr. Hurley stated that 226 ships of 863,000 deadweight tons have already been allocated to Latin American trade and the Shipping Board is now surveying the situation to establish regular American lines to ply between all the important ports of North and South America. The plans call for two lines from New York to serve the West Indies, a line from Valparaiso and other western ports to Mobile or New Orleans, a line of service between Valparaiso and Seattle, New York and Rio de Janeiro and other similar systems.

Ships will be used capable of 23½ knots per hr. which, stated Mr. Hurley, will reduce, for example, the time between Buenos Aires and New York from 24 days to 15 days. This will have an important effect upon first-class and parcel post mail and upon capital or business.

Development of the parcel post arrangements was urged by Otto Praeger, Second Assistant Postmaster General.

Individual representatives of the various Latin American countries told of the desire of continued and increased commerce with the United States. Statistics were quoted to show the increase in business in the past few years, one of the most astonishing reports being that on Cuba, which, with a population of slightly more than 2,000,000, had a foreign trade of $680,000,000.

3-LITER LIMIT FOR FUTURE RACES

(*Continued from page* 1207)

plies to the Detroit Special, which had leaky water connections.

It is quite apparent that Ralph De Palma and Louis Chevrolet would have been further up in front toward the end and would probably have given each other and the winners a breathless contest for first honors if they had dodged their troubles. In fact, both of these drivers made major repairs on their cars during the race and yet finished well up in the money. Louis Chevrolet had to stop seven times. These cars did not possess sufficiently strong axles to withstand the great acceleration made possible by the powerful engines. A broken steering knuckle on one of the cars, a broken right rear hub on another, and a left rear wheel coming off, and a third, because of failure of the aluminum shell construction in the rear axle, tell the story of the Frontenac in the race. It was only by exceptional driving that the Chevrolets were able to finish with two of their Frontenac cars.

NO TAX REPEALS NOW

WASHINGTON, June 3—The possibilities of a repeal of the taxes on motor trucks, which have been considered likely by the industry, do not appear favorable at present. Congress apparently is opposed to the repeal of any taxes and is even objecting to the repeal of the soda water tax, which it is said by many to be very unjust.

Men of the Industry

Changes in Personnel and Position

BROWNE OAKLAND MANAGER

NEW YORK, May 31—Charles M. Browne, president of the Automobile Dealers' Association, Inc., of New York City, and for the past 10 or 11 years manager of the New York branch of the Winton Co., has severed his connection with Winton. On June 1 he becomes manager in New York for the Oakland Motor Car Co., which will convert its dealership into a factory branch. Mr. Browne first became connected with the Winton company in 1905 in that company's Chicago branch. After half a year there he was sent to San Francisco to open a branch on the Pacific Coast and a year later came to New York.

He is succeeded by H. J. C. Miller, who has been his assistant.

Coincident with the change, the Oakland business, which has been handled by the Sidney A. Bowman Co. since 1913, will be removed to the C. T. Silver building. The contract between the Oakland company and the Bowman company does not expire until July 1. The Bowman company has not yet made public its plans for the future.

Birger Jacobsson, manager of the Scandinavian division of J. B. Crockett Co. and the Clyde Cars Co., is in the United States for a short stay and will return to his territory soon.

A. H. Savage has been appointed sales representative of the Roller-Smith Co., New York, for Minnesota, North Dakota and part of Wisconsin and South Dakota, with headquarters in the Pioneer Building, St. Paul. Prior to 1914, Mr. Savage represented the Ft. Wayne Electric Works, and since 1914 has been representative in St. Paul of the Wagner Electric Manufacturing Co., St. Louis.

F. W. Marshner has been appointed manager of the Detroit branch of the New Departure Manufacturing Co., Bristol, Conn., succeeding the late Samuel B. Dusinberre. He has been in the Detroit office of the company for nearly seven years.

John R. Marchant, son of George F. Marchant, president of the Geo. F. Marchant Co., Chicago, and himself a member of the firm, was killed in action in France on Oct. 11, 1918, fighting as first lieutenant in the 131st Infantry of the A. E. F.

L. B. Fijux has been appointed Detroit district representative of the automobile equipment department of the Westinghouse Electric & Manufacturing Co., with an office in the Kresge Building. T. G. Haugh will assist him. Mr. Fijux was assistant manager of the Willard Storage Battery Co. for six years and manager of the Detroit office of the Bijur Motor Appliance Co. for five years. He succeeds W. A. Haines, who died last February.

Bernard M. Robinson has recently been appointed resident counsel and head of the legal department of the Firestone Tire & Rubber Co., Akron, taking over the duties of Mr. Hamill, who has been appointed secretary to President Harvey S. Firestone.

ARMLEDER ADDS SALESMEN

CINCINNATI, June 2—W. D. Thompson, formerly wholesale manager of the Lexington Colorado Auto Co., has joined the sales force of the O. Armleder Co. as western representative with headquarters in Denver. Jack Parker, with the Oldsmobile organization for the past five years, is also connected with the Armleder concern, and Charles F. Ward, Providence, R. I., is covering Massachusetts and Connecticut for the company. C. B. Harvey will have charge of the Middle West with headquarters at Chicago.

FRIEDE JOINS HAYNES

KOKOMO, IND., June 4—Julian S. Friede, recently released from the British Royal Flying Corps, has joined the engineering staff of the Haynes Automobile Co. Previous to his aviation service he was on the engineering staff of the Paige Detroit Motor Co.

Frank R. Boyd has resigned as assistant treasurer of the Oakland Motor Car Co., Pontiac, and will devote his time to personal affairs.

M. V. Smith has been made general superintendent of the Supreme Motors Corp., Warren, O. He was production manager of the Essex engine at the Hudson Motor Car Co. plant, Detroit.

W. S. Stevenson, general sales manager of the Bethlehem Motors Corp., Allentown, Pa., since its organization, has resigned on account of ill health.

Roy S. Davey succeeds W. S. Stevenson, who recently resigned as general sales manager of the Bethlehem Motors Corp., Allentown, Pa. Mr. Davey was formerly on the sales staff of the Chandler Automobile Co. and of the Packard Co. He has been with the Bethlehem Motors since its organization. Mr. Clay will succeed Mr. Davey as assistant general sales manager in charge of sales promotion.

Charles A. Greene, Chicago representative of the Borden Co., Warren, O., has opened an office for the company in Room 501, 549 West Washington Boulevard.

Edward A. Hefferman, recently returned from naval aviation service, will have charge of the office of the Ahlberg Bearing Co., recently opened in the City Bank Building, Kansas City, Mo.

C. E. MacTavish, who has been manager of the Chevrolet Motor Co. branch at Regina, Sask., has been transferred to the head office at Oshawa, Ont.

E. T. Causer has recently resigned as works manager of the R. D. Nuttall Co., Pittsburgh.

STANDARD PARTS VICE-PRESIDENTS

CLEVELAND, June 2—Dan C. Swander and John G. Utz have been elected vice-presidents of the Standard Parts Co. Mr. Swander will continue as supervisor of sales and Mr. Utz as supervisor of engineering. Both men have been with the company since its organization. Mr. Utz was formerly director of engineering of the Perfection Spring Co. Mr. Swander previously was eastern sales manager of the Firestone Tire & Rubber Co.

C. H. Bassett, Detroit, has been appointed a southern district sales representative by the Fulton Motor Truck Co., Farmingdale, L. I. He was formerly with the Studebaker Corp. and the Elgin Motor Car Corp. and was a dealer and distributer at Jacksonville, Fla.

George W. Brooks has been appointed representative of the Hudson Motor Specialties Co. for Texas, New Mexico, Oklahoma, Kansas and Arkansas.

Major Howard Blood, connected with the airplane experimental station at Dayton during the war, has been appointed general manager of the plants of the General Motors Co. at Walkerville, Ont. Two plants are now being built for manufacture of engines and axles.

Stephen A. Douglas, Detroit Section S. A. E., has been appointed chairman of the committee on activities at the annual mid-summer meeting at Ottawa Beach in June.

M. B. Hoagland has been appointed director of sales of the Signal Motor Truck Co., Detroit. He was with the American Steel & Wire Co. for 17 years.

J. Gordon has been appointed middle western sales representative of L. V. Flecher & Co., New York City.

UNIVERSAL TOOL SALESMEN

DETROIT, June 3—The Universal Tool Co. has appointed A. E. Hrobskey to cover New York and the New England states, with an office in New York. C. E. Hinckley will cover Pennsylvania, New Jersey, Maryland and Delaware, with headquarters at the York, Pa., factory. J. E. Nebrick will cover Ohio, Michigan and Indiana, with headquarters at the Detroit office. Merritt Campbell will cover Illinois, Missouri and Iowa, working from the Indianapolis office. Beginning June 1, the main office of the company will be in the McKerchey Building, Detroit. In the last few months the company has opened factories in Detroit and Windsor, Ont., in addition to the plant in York, Pa.

EMPIRE AXLE REORGANIZED

DUNKIRK, June 2—The Empire Axle Co. has been reorganized with a capital of $400,000, as a subsidiary of the Watson Corp., Canastota, N. Y., with the following officers: President and assistant treasurer, O. F. Hakes; vice-president, chief engineer and assistant secretary, E. de H. Caldwell; sales and advertising manager, R. W. Foley. It plans to increase the capacity of its plant.

RECEIVER FOR MAXIM

NEW YORK, June 2—The Maxim Munitions Corp., which was formed in 1915 with $10,000,000 capital, to take over the inventions of Hudson Maxim, and which in June, 1918, announced its intention of making and marketing a farm tractor, as well as acting as domestic and export distributer for the trucks manufactured by the Dart Motor Truck Co., Waterloo, Iowa, has been placed in the hands of a receiver. The courts have appointed H. H. Henry, who for the past two months has been president of the company and prior to that was vice-president and general manager.

It is understood that the assets and liabilities of the company are about $1,000,000 each, and it is stated that there appears an excellent possibility of the company being reorganized and continued. Until the creditors and stockholders meet, however, nothing definite can be stated with regard to future plans. A meeting is scheduled for the near future and in the meantime the business will be temporarily discontinued.

NEW CHEVROLET SALES ZONES

FLINT, MICH., May 31—The Chevrolet Motor Co. has just created seven new sales zones in the United States and one in Canada. This gives the company a total of 15 sales zones in the United States and two in the Dominion. One of the new zones will have its headquarters in Chicago and another in Cincinnati, where the Chevrolet company is already operating retail sales branches. The wholesale departments in these two cities will start business Aug. 1. The Cincinnati department will be in charge of John Flynn, who was with the Baltimore branch for 4 years. H. H. Monday, for several years connected with the Washington branch, has been transferred to Chicago to handle the wholesale business there.

While the Chevrolet company has been operating on a fixed schedule of 700 cars a day, this production is constantly being exceeded, the average production for last week being 726 cars.

KENTUCKY WAGON BUILDING

LOUISVILLE, KY., June 2—The Kentucky Wagon Manufacturing Co. will begin on Aug. 1 the construction of a new 2-story steel and brick building costing approximately $100,000. According to present plans the structure will be occupied by the car, upholstering, paint and assembly departments, which are part of the car and truck branches. The plant of the Kentucky Wagon company at the present time consists of 32 acres.

LANSING BODY DOUBLES SPACE

LANSING, June 3—The Lansing Body Co. has started the erection of a new building which will double the present floor space. The new structure will house the painting and finishing department.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

NEW COLUMBIA FACTORY

DETROIT, June 3—The Columbia Motors Co., which has been contemplating an addition to its plant for some time, has purchased from the Detroit Seamless Tubes Co. 6 acres of ground, on which a new factory will be erected. The proposed plant will be completed by Jan. 1, 1920. It will have a floor space of 150,000 sq. ft. Part of the site is occupied by the Fisher Body Corp.

OLD TRUCK PLANT SOLD

WYANDOTTE, MICH., May 28—The old plant of the Detroit-Wyandotte Motor Truck Co. has been sold to John J. Marx of Detroit. It has a floor space of 40,000 sq. ft., and is located on a 2½-acre site. The plans of the purchaser have not been announced.

REPUBLIC SPECIAL BODIES

ALMA, MICH., June 2—The Republic Motor Truck Co., Inc., is furnishing dealers with a complete line of special bodies made to their specifications. These bodies are built entirely by the Republic body department and can be mounted on trucks at the factory or shipped separately.

PARKER GETS MORE CAPITAL

MILWAUKEE, June 2—Capitalization of the Parker Motor Truck Co. was increased from $350,000 to $500,000 in the form of preferred stock at the annual meeting of the company. Adam J. Mayer was re-elected president and other officers are: Vice-president, F. H. Parker; secretary-treasurer and general manager, L. L. Newton. Directors were re-elected.

TOOL SALVAGE DROPS PENINSULAR

DETROIT, June 2—The Peninsular Tool Salvage Co. has changed its name to the Tool Salvage Co. This action is taken because of the difficulty customers found in spelling and pronouncing the word "peninsular."

ATTWOOD BRASS MOVES

GRAND RAPIDS, MICH., June 2—The Attwood Brass Co. is moving from its present plant into much larger quarters, having purchased a 2-story factory building formerly occupied by the Steel Furniture Co.

LAKESIDE FORGE ADDS

ERIE, PA., June 2—The Lakeside Forge Co. is adding a building 104 x 81 ft., of brick and steel, for increasing its office and shipping space.

MERGER PROGRESSES

NEW YORK, June 2—Negotiations pointing to an early merger of the International Motor Co. and the Wright-Martin Aircraft Corporation are indicated by operations which have been in progress for some time. It is expected that next week the stockholders of the Wright-Martin organization will approve a plan whereby the New Brunswick factory of Wright-Martin is sold to the International Motor Co. in exchange for stock in the latter organization. The factory will be used at increased capacity for the manufacture of trucks and should permit of the International doubling its truck output. The New Brunswick factory has 500,000 sq. ft. area and has been used to manufacture Hispano-Suiza engines during the war.

The Wright-Martin Corp. will be reduced in capitalization and continue to exist as an aircraft corporation for the carrying on of necessary aircraft development and manufacturing work.

The International Motor Co. has not announced any definite plans as to whether the New Brunswick factory of the Wright-Martin will be used solely in the manufacture of truck engines or if Mack trucks will be manufactured in their entirety there.

TRACTORS FOR FRANCE

SANDUSKY, OHIO, June 2—The Dauch Manufacturing Co., makers of the Sandusky tractor, has received an order for the immediate shipment of 500 of their 10-20 model J tractors to France to be used in reconstruction work. Two hundred machines will be the standard 10-20 model J type, the balance being for a new frameless type model which the Dauch company has just perfected. Shipments are going forward at the rate of 25 a week.

HIGHWAY MOTORS TRUCKS

CHICAGO, June 2—The Highway Motors Co. has recently been incorporated to build American Knight-motored trucks in 3½- and 5-ton capacities. It has purchased the assets of the Motor Trucks, Ltd., Brantford, Ont.

OMOLITE CREDITORS TO MEET

JAMESTOWN, N. Y., May 29—A meeting of the creditors of the bankrupt Omolite Co., Inc., has been called for June 11, in the Federal Court Room of this city to pass on the reports and account of distribution of funds on hand when the case is closed.

The financial account, as it stands, is as follows:

Receipts from sale of assets		$10,000.00
Disbursements, administration expense	$743.76	
Preferred claims	1,447.05	
First dividend paid	4,158.74	
Total		6,349.55
Balance on hand		$3,650.45

PACKARD EXTRA DIVIDEND

Packard Motor Car Co., Detroit, 2½ per cent extra dividend in addition to regular 8 per cent dividend.

Automobile Trade With Allies Discussed

Car Makers and U. S. Officials Talk Over Export Problems of the Immediate Future

WASHINGTON, June 2—The Allied governments and peoples are disposed to regard the United States unfavorably because of the stand of the American Peace Commission against large indemnities from Germany, and as a result it is difficult for the State Department to approach the Allies on any commercial questions, without danger of creating a wider diplomatic breach, was the statement of foreign trade advisers of the State Department to-day to members of the export committee of the National Automobile Chamber of Commerce.

This statement was made in reply to the expressed belief of the export committee that its members thought that immediate resumption of normal business conditions would work best for both the Allies and the American manufacturers. "All the cars sold in the allied countries of American manufacture," they stated, "will help those nations to recover, and will not interfere with their own automobile manufacture."

England, it was pointed out, is paying 100 per cent above the list price of new cars for used cars.

The meeting was attended by W. Frost, C. H. Albrecht and A. C. Millspugh of the Department of State, J. Walter Drake of the Hupp Motor Co., J. Rathbun of the White Co., P. S. Steenstrup, General Motors Corp., C. G. Young, Willys-Overland Co., Louis Domeratzcy, Department of Commerce, Alfred Reeves, Pyke Johnson and H. R. Cobleigh of the National Automobile Chamber of Commerce.

The disadvantages of the American tariffs, which include a 45 per cent duty on automobiles imported into this country valued at $2,000, and 30 per cent on those under $2,000, was pointed out by J. Walter Drake. The foreign countries sell the United States only high priced cars and as they have to pay a 45 per cent duty on these, they are inclined to regard our entire tariff duty as 45 per cent, and consequently in enacting their tariff laws base them on an American 45 per cent duty. Recommendations for the repeal of this duty with a straight 30 per cent tariff in its place were made. The government department officials replied that this matter could be handled only through Congress when it revises the tariff.

C. H. Albrecht said that the American Ambassador in France is trying to get the French government to remove its embargoes and restrictions on American cars and parts. Nothing can be done through diplomatic channels toward effecting reduction in the French tariffs, it was stated, until after the American tariff is revised.

The fact that France is not in favor of the sale of the American army cars and trucks to individuals in France met with serious objection from the automobile export managers. Peter Steenstrup stated that there are about 1900 Cadillac passenger cars in France with the American army, and if these are bought by the French government and later sold to individuals, according to present plans, the General Motors Corp. fears that there will be no attempt to furnish parts or service, and the reputation of the company may suffer in consequence. He stated that if France will remove its embargo and allow parts to be shipped into the country, the General Motors Corp. will undertake to provide parts and service for Cadillac owners.

It was also suggested that this government should take steps to have France change its plan to allow cars to be sold by the American army. The government officials stated that this was a War Department matter and must be taken up by the N. A. C. C. through the War Department.

The delays in the mails and cables and the British censorship were stated by Drake to be serious obstacles to American foreign trade at present. The State Department announced that all censorships to neutral countries by Great Britain had been abolished and that a protest has been made by this government against all other mail censorship by England, in which it was asserted that the information obtained from this censorship is being used for the benefit of British manufacturers. Great Britain has replied denying this and the American government is seeking specific instances. It was further stated that there is no censorship on cablegrams to the Far East and that any delay is due to congestion.

An interpretation of the British restrictions on American automobile exports to 50 per cent of the 1913 exports was given by Louis Domeratzcy. He said that instead of this percentage applving to the exports of that year, it applied to the imports. Importers who were in business in 1913 can import from the United States 50 per cent of the imports for that year, regardless of the makes and types. This interpretation removed the fears that manufacturers who had started in business in 1913 would not be able to ship cars under the British ruling.

A statement that Germany will likely resume normal trade conditions before any of the Allies can get back into peace time production was refuted by government officials, who stated that the peace commission found conditions in Germany so bad that it had to cut down the indemnity and that, because of this, the Allied experts are certain that German commerce cannot be resumed in the near future.

The government officials were asked to make arrangements with the British government so that automobile manufacturers with branches in Canada will know what percentage of cost must enter into an automobile manufactured in Canada to overcome the British restrictions. They asked the government officials to make such arrangements, if possible, whereby a car assembled in Canada, with 50 per cent of the cost in assembling, and 50 per cent in the parts exported from the United States, will be recognized by Great Britain as a Canadian product.

Requests were also made by the N. A. C. C. for more government investigators of foreign car markets. The answer was that the appropriations to the departments are insufficient to allow the sending of more men to foreign countries at present.

If the manufacturers will send their own investigators abroad, it was stated, the Department of State will arrange that these men can have full co-operation of the consuls.

Although there was no definite result from the meeting, it was felt that the problems had been properly placed before the government officials and the way opened for definite results at future meetings.

Tax Hearing Promised to Car Builders

Chairman Fordney Tells N. A. C. C. Committee He Is in Sympathy with Plea

WASHINGTON, June 2 — Alfred Reeves, manager of the National Automobile Chamber of Commerce, and a party of automobile manufacturers called on the House of Representatives Ways and Means Committee to-day and were assured by Chairman Fordney that they would be granted a hearing on the subject of manufacturers' tax as soon as it was possible to arrange it.

Mr. Fordney assured the automobile men that he was in entire sympathy with their plea for the removal of the manufacturers' tax. First, however, it would be necessary to remove the so-called luxury tax, that on clothing and similar articles. As soon as that is disposed of, the committee will be willing to take up the manufacturers' tax. One important condition in considering the removal of this tax is the need of the government for money. The manufacturers, he said, would do well to remember that government expenses are still running high.

Mr. Reeves said that it had been intended to take up this matter with the Ways and Means Committee to-morrow, but their success in meeting Chairman Fordney made it unnecessary to stay over. As soon as the date is set for the hearing, notice will be given to the National Automobile Dealers' Association, the Automobile Jobbers' Association, the Motor Accessories and Manufacturers' Association, the Rubber Association and other organizations which have been helpful in presenting this matter to government officials. The plan now is to urge the repeal first of the parts taxes, second, of the tax on motor trucks, and third, on the passenger cars.

2750 Mile Flight Planned by Army

Martin Bombing Airplane Will Fly Across Continent from Mineola to San Francisco

WASHINGTON, June 3—The War Department announces that the Army Air Service has planned a one-stop transcontinental flight of 2750 miles, by a Martin bombing airplane to be undertaken within a few days. Capt. Roy N. Francis and 1st Lieut. E. A. Cline will pilot the machine. Two or three mechanics will be carried.

The start will be made from Mineola, N. Y., field. The stop will be at North Platte, Neb. San Francisco is the destination. The tentative schedule calls for an average speed of 100 m.p.h. The distance from Mineola to North Platte is 1502 miles, the next leg being 1248 miles. The plane will start from Mineola at 3.30 a. m. on a day to be set. It will stop at North Platte from 8.09 p. m. that evening until 3.30 a. m. the following morning, and is scheduled to arrive at San Francisco at 5.58 p. m.

The Air Service authorized the following description of the machine in which the transcontinental flight will be attempted:

Martin Military Bomber Selected

"The United States Martin bomber is the airplane selected by Capt. Roy N. Francis to attempt the one-stop transcontinental flight because of especial suitability. The airplane was originally designed for military purposes as a day or night bombing plane or for long distance photography.

"The power is supplied by two Liberty motors of 400 horsepower each, mounted in the wing gap on each side of the body. The body is well designed and commodious. At the nose is the cockpit for the front gunner. He has access to a passage through which he can go aft to handle the rear lower gun or sit beside the pilot on a folding seat. The pilot is placed on the right hand side of the body and well up, so that his range of vision is the best possible. He is provided with a wheel type control and has a splendid view of the instrument board. Behind the pilot are the three main gasoline tanks. To the rear is a mounting for the lower gun, which commands a large field of fire to the rear, below and to both sides.

"The wing structure is very light. The designer was particular to observe the principles of stream line, rigidity and strength. The total wing and control area is 1355 square feet. The span of the upper and lower wings is 71 feet 5 inches and the depth of each wing is 7 feet 10 inches. The gap between the wings is 8 feet 6 inches. The length over all is 46 feet and the height over all 14 feet 7 inches.

"The under carriage is composed of four 800 by 150 mm. wheels. The axles are hung on the usual rubber cord suspension, but have a great amount of freedom not only vertically but in the other two directions. All of the lateral forces are taken up by the centre trussing under the body. The two outside struts are free to swing laterally, and hence only absorb the vertical component of the landing shock. A single wheel and foot bar control is provided for the pilot's cockpit.

"There are four equal ailerons for the maintenance of lateral stability. The tail services are of steel and wood construction. The elevator is one piece and with its generous area and ease of operation forms a positive control to be relied upon in any emergency. Two balanced rudders working in synchronism permit the pilot to control his direction under any conditions with ease. In fact, when flying with one engine dead, the amount of rudder necessary to correct the offsetting force of the other engine is surprisingly small.

"Three sturdy gasoline tanks, mounted securely inside of the body, contain the main supply of gasoline. This airplane is particularly adaptable to the requirements of civil aeronautics—for passenger, mail and express service, coast, border and forest patrol. This adaptation would not involve any important changes, for the same machine less the military equipment is immediately serviceable for the carrying of one ton of mail or of twelve passengers at a speed of from 100 to 105 miles per hour. Requirements of safety, so important in our transport, are especially well fulfilled by this machine because it can fly and climb on one engine."

NC-4 Averages 78.7 M.P.H. From Rockaway to Plymouth

NEW YORK, June 3—Secretary of the Navy Daniels has ruled that the NC-4, which concluded its flight to Plymouth, England, May 31, shall be brought home by ship. This decision was based on the argument that the NC-4, the first airplane to cross the Atlantic, should not again be risked in long flight but should be sent home and properly preserved as an historical relic. Some naval men thought the NC-4 should try a non-stop flight home, or a flight with only one fuel stop in mid-ocean. It was decided, however, that seasonable winds made a successful westward non-stop flight highly improbable. Lieut.-Commander Read and the NC-4 crew have been much feted in England and visited Paris at the request of President Wilson. The NC-4 record, as unofficially compiled at Washington, is:

Course	Date, May	Distance, Miles	Time, Hrs.	Speed, M.P.H.
Rockaway-Chatham (forced landing about 100 miles off Chatham)	8	345.45	5.45	59.87
Chatham-Halifax	14	368.42	3.51	97.87
Halifax-Trepassey	15	529.69	6.20	83.60
Trepassey-Horta	16-17	1,381.81	15.18	90.27
Horta-Ponta Delgada	20	172.72	1.45	99.83
Ponta Delgada-Lisbon	27	921.21	9.44	94.50
Lisbon-Mondego River	30	115.10	2.07	56.20
Mondego River-Ferrol	30	253.30	4.37	52.50
Ferrol-Plymouth	31	523.30	6.59	74.60
Complete Flight—				
Rockaway to Plymouth	8-31	4,519.70	57.16	78.70
Transatlantic Flight—				
Trepassey to Lisbon	16-27	2,150.00	26.47	80.30

FRENCH PLANES TO U. S.

WASHINGTON, June 2—Following the settlements of contracts with France for airplanes, it is estimated that 600 Spad-4 airplanes, 1000 Nieuport-28 airplanes, 1000 Hispano-Suiza 220 hp. engines and 800 Gnome Monosoupape engines will be available for shipment to the United States. There is still on order with France a contract for Hispano-Suiza 300 hp. engines, 406 of which have been delivered, leaving 94 still on order.

Twenty-one per cent of the total number of De Haviland-4 airplanes produced before the armistice reached the zone of advance before hostilities ceased. Following is a table showing the production and distribution overseas of the De Haviland airplanes:

		Per cent of total produced
Produced	3227	100
Floated	1885	58
Received, A. E. F.	1440	45
Dispatched to Zone of Advance	667	21
Dispatched to training fields, A. E. F.	293	9

CAPITAL INCREASES

NEW YORK, June 3—The B. F. Goodrich Co., Akron, proposes an increase in capital from $84,000,000 to $109,000,000. The $25,000,000 new stock will be preferred, and $15,000,000 will be sold immediately to holders of common and preferred stock. The sale of this additional stock is to provide funds to take up $15,000,000 2-yr. notes maturing next November.

The Fisk Rubber Co., Boston, will offer to stockholders $15,000,000 new first preferred stock and $2,500,000 new second preferred stock. Present first preferred stockholders of record June 10 and present second preferred and common stockholders of record July 15 will have the right to subscribe. Funds from this sale will be used to retire the $4,025,000 outstanding first preferred and $5,000,000 convertible first preferred stock and will leave an increase in the capital of the company of $8,475,000.

March Petroleum Stock Satisfactory

PRODUCTION

	March 1919	February 1919
Crude oil (bbl.)	27,886,775	25,232,876
Gasoline (gal.)	311,306,755	285,518,194

STOCKS ON HAND

	March 31, 1919	Feb. 28, 1919
Crude oil (bbl.)	15,106,361	14,820,601
Oils purchased to be re-run (bbl.)	1,121,963	1,176,483
Gasoline (gal.)	546,062,429	458,449,187
Kerosene (gal.)	294,677,623	303,062,436
Gas and fuel oil (gal.)	749,067,806	692,816,000
Lubricating oil (gal.)	165,495,254	152,297,163
Wax (lb.)	235,588,922	209,908,707
Coke (ton)	37,642	33,716
Asphaltum (ton)	113,949	102,547
Miscellaneous (gal.)	468,035,524	500,413,825

WASHINGTON, June 4—Although production of crude oil and gasoline for March shows an increase over the February figures, the fact is discounted by the circumstance that March has 31 days against February's 28. Nevertheless the position continues satisfactory.

Stocks on hand indicate a healthy condition, particularly in regard to gasoline, which is substantially in front of February and is nearly 20,000,000 gal. better than March, 1918. Gasoline and fuel oil and also lubricating oil show an appreciable gain when compared with February totals and an even greater advance over the figures of a year ago.

The comparative analysis of production and consumption of gasoline, kerosene, gas and fuel oil and lubricating oil for the first three months of 1919 and 1918, as shown in table herewith, indicate a satisfactory position. With the exception of the kerosene item matters are now distinctly better than was the case in 1918.

—

AIR MAIL CARRIES 408,560 LETTERS

WASHINGTON, June 3—The Chicago-Cleveland Air Mail Service, during its first half month, has made a daily 100 per cent performance, except two half trips May 21 when the field at Bryan, Ohio, was so flooded that the planes could not rise from the ground.

Out of a possible mileage of 11,050, a total of 10,725 was accomplished, making a performance of 97.1 per cent and 408,560 letters carried. Since May 21 the daily trips in each direction are about 325 miles, non-stop. Twenty such non-stop trips were made without engine trouble of any kind, and with a single mishap in the nature of a fire in the pilot's cockpit of a plane operated by Pilot Frank McCusker, resulting in the death of that pilot. This has been the only fatality to any pilot carrying the mail since the service was established May 15, 1918.

The long distance non-stop flights on the Chicago-Cleveland route are being performed by the De Haviland planes strengthened for cross country mail carrying and equipped with low compression Liberty engines. The best time made on any trip between Chicago and Cleveland was 2 hr. 42 min. for 325 miles, and the longest trip was 4 hours, due to a bad head wind. The average speed for the half month was 98½ m.p.h. and the average gas consumption was 23 1/5 gal. per hour. The mail leaves Cleveland and Chicago at 9.30 o'clock each morning, including Sundays, and arrives at its destination usually between 12 and 1 o'clock in the afternoon.

Airplane Provides for Mail Clerk

WASHINGTON, June 3—Recent requests for bids for airplanes by the Air Mail Service resulted in eight bids, of which the lowest are from the Lawson Air Line Co., Milwaukee, which has designed a plane embodying mail car equipment, and allows for the employment of a mail clerk en route. The engines will be installed by the government and it is expected that the Liberty engine will be used.

The airplane is of the biplane type, with the chassis built between the two wings, with engine space provided at each side. There is sufficient space so that the men can walk around the body, which is enclosed in glass. A rack has been designed in which the mail may be distributed during the flight, and a drop chute allows for the discharge of mail bags at principal cities without stops. A model of the plane has been ordered and will be demonstrated here when completed.

CLASS B RULES FOR TRACTOR TESTS

(*Continued from page* 1237)

width will be obtained by measuring the width plowed, from outside to outside edge of furrow, measured every 10 rods as indicated by mark stakes, and then deducting the width between the mark stakes which is not included in the test. The rate of travel during the dynamometer test should be the same as during the plowing period.

7B—Before the test commences the fuel tanks will be filled to the top with tractor set level. The run will be made on one fuel only to eliminate the necessity of including two fuels in the final result. If kerosene is to be used, the motor may be warmed up on gasoline and the fuels switched just before starting the test. The fuel will be supplied the entrant from a common source in the field.

8B—The water will be measured by the same method as used in measuring fuel. The water used in the cooling system will be kept separate from that used with the fuel and air washer.

9B—The rate of travel will be adjusted in the preliminary rounds so as to come within 10 per cent of the rated speed.

The same rate of travel should be maintained throughout the test and the observer will keep an accurate check on this by timing every second round, excluding the time required in turning at all stops and at the ends. However, the time consumed for turning at ends will be included in the plowing time.

10B—The plow will be adjusted in the two preliminary rounds and no change of adjustment will be permitted during the test and including the first preceding and following rounds when the dynamometer tests are made.

11B—The depth will be checked every 10 rods in order to obtain accurate average of the depth plowed. These distances will be indicated by mark stakes.

The plow will be set for the upper depth before the test is started and that depth maintained throughout the test.

12B—The width cut by the inside plow will be checked by the observer at least every second time depth is taken and the operator will be required to maintain even cut.

13B—If in the aggregate it is found necessary to stop the tractor more than thirty minutes, the test is annulled.

14B—This rule, at the discretion of the committee, provides an opportunity to re-enter an outfit that has been disqualified.

15B—Much of the data will be available and turned over to the company representative promptly at the completion of each test, but the committee reserves the privilege of checking it and will submit the complete results in standard forms before 10 p. m., for all tests conducted during the day.

All data will be made public unless a manufacturer, for any reason, desires to withdraw the results of some machine and then no part of such data may be issued later.

MINERAL OIL EXPORTS FOR APRIL

WASHINGTON, May 29—Fewer gallons of mineral oil were exported last month as compared with a year ago, but the value shows a marked increase. The figures are: April, 1919, 208,515,323 gal. valued at $27,893,100; April, 1918, 227,998,969 gal. valued at $25,689,393. Gasoline exports total 27,546,646 gal. valued at $6,981,164 for April, 1919, as compared with 46,857,293 gal. valued at $11,280,216 for April, 1918. Following are the detailed exports:

Oil Exports for April and Ten Months Ended April, 1919

	1919		1918		1919		1918	
	Gallons	Value	Gallons	Value	Gallons	Value	Gallons	Value

STARTER PRODUCTION DOUBLED

ADRIAN, MICH., May 28—The Adrian Steel Castings Co., which is making an automobile starter, has found it necessary to increase its force to meet the demand for the product. The company is producing approximately 100 starters a day, but with a night shift in action 200 starters will be turned out daily.

Calendar

SHOWS

*Oct. 15—Paris. Grand Palais. International Automobile Mfrs. Congress.

Nov. 7-16—London. Olympia Motor Car Exhibition—Society of Motor Mfrs. and Trades.

December — Brussels. International Automobile Mfrs. Congress.

January—New York. International Automobile Mfrs. Congress.

February — Chicago. International Automobile Mfrs. Congress.

Feb. 23-Mar. 6 — Birmingham, Eng. British Industries Fair.

TRACTOR SHOWS

June 9-12—Denver, Colo. Sectional Tractor Demonstrations, Denver Tractor Club.

July 14—Wichita. Kan. Automotive Committee of National Implement Assn.

July 28-29—Columbus, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 1-2 — Piqua, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 6-7—Fostoria, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 12-13—Akron, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 18-22—Aberdeen, S. D. Sectional Tractor Demonstrations.

October—Ottawa, Ont., Can. Interprovincial Plowing Match and Tractor Demonstration.

CONTESTS

†June 14—Sheepshead Bay, L. I. Speedway race.

July 4—Tacoma, Wash. Annual speedway races.

July 4—Atlantic City, N. J.—Airplane races—Aeronautic Convention.

*July 5—Cincinnati, O. Speedway.

*July 19—Uniontown, Pa. Speedway race.

*July 26—Sheepshead Bay, L. I. Speedway race.

*Aug. 15 — Middletown, N. Y. Dirt track event.

*Aug. 22-23—Elgin, Ill. Road race.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Sept. 27—Allentown, Pa. Dirt track event.

*Oct. 1—Cincinnati, O. Speedway race.

*Oct. 4—Trenton, N. J. Dirt track event.

*Oct. 11—Danbury, Conn. Dirt track event.

*Tentative dates.
†Sanctioned.

CONVENTIONS

June 2-6—Hot Springs, Va. Convention Automotive Equipment Assn., Homestead Hotel.

June 3-6 — Washington. Pan-American Commercial Conference, Pan-American Building.

June 12-14—Pittsburgh. Annual convention of American Drop Forge Assn. and Drop Forge Supply Assn., William Penn Hotel.

June 16-19—Detroit. American Society of Mechanical Engineers spring meeting, Hotel Statler.

June 23-28—Ottawa Beach, Mich. S. A. E. Mid-summer Meeting.

Sept. 22-24 — Philadelphia. Annual Convention. National Association of Purchasing Agents. Bellevue-Stratford.

May 12-15, 1920—San Francisco. Seventh National Foreign Trade Convention.

TRACTORS IN CUBA

WASHINGTON, June 2—The tractors used on the sugar estates of Cuba, according to consular report, are of two kinds: the round wheel and the tracklayer types. They are used almost exclusively for plowing. In the northern section of the Cienfuegos Province, owing to the hard, sticky, clayish soils, the tracklayer type seems to be most successful, as it is claimed that round wheel tractors constantly slip with the consequent loss of power and breakdowns. In the central and southern part of this district, the round-wheel tractors seem most successful.

In the southern section tractors of 8 to 16 and 12 to 25 hp. have been used to some extent for hauling purposes as well as in connection with cane planting machines. Experiments have also been made here with the tracklayer type for cultivating between the rows of cane. The chief objections to this type seem to be that its first cost is much higher than the round wheel; that it is complicated and therefore more liable to breakage, and more difficult for inexperienced operators to handle. Several plantations are to experiment with different kinds of tractors, and especially with the tracklayer type, for the purpose of hauling cane.

JAPANESE ROADS LIMIT CARS

WASHINGTON, June 2—Japanese roads and bridges are so unsatisfactorily constructed that the government is obliged to limit the weight of automobiles to 3000 lb. and trucks to 2 tons complete, with the body weighing not more than 5800 lb., according to a letter received by the Highway Industries Association. A few cities and towns have streets and roads that are practical for passenger hauling, but 90 per cent of these have unsatisfactory bridge conditions. The roads are narrow and it is difficult for two machines to pass. Close to the cities, however, roads have greater width and two trucks can pass without scrapping mudguards.

In Tokyo the majority of the streets are from 18 to 20 ft. wide. On all streets under this width a permit from the police is required for travel. There are no sidewalks, and congestion consequently is heavy. The Japanese have not become accustomed to right and left traffic rules and usually keep to the middle of the road.

The Japanese Government has sent a commission of engineers to the United States to study highways and it is expected that this commission will recommend a construction of a national highway system to relieve the present conditions.

China is also looking into the question of improving her highways, and one of the peace commissioners, Dr. Wang, is collecting data on road administration and construction, and will soon visit the United States to make a personal study of this problem.

REVISED TAX RULING ISSUED

(*Continued from page* 1240)

session an order or contract of sale, with certificate of the purchaser in writing printed thereon or permanently attached thereto, showing that the tires, inner tubes, parts, or accessories so purchased are to be used in the manufacture of new automobile trucks, automobile wagons, other automobiles, motorcycles, tires, inner tubes, parts, or accessories or for sale on automobile trucks, automobile wagons, other automobiles, or motorcycles or in connection therewith or with the sale thereof or for free replacement under contract or guaranty. Following is a form of the certificate or statement which will be accepted:

The undersigned hereby certifies that the tires, inner tubes, parts, or accessories purchased hereunder are purchased with the intention of using them in the manufacture or production of automobile trucks, automobile wagons, other automobiles, motorcycles, tires, inner tubes, parts, or accessories, or for the sale on automobile trucks, automobile wagons, other automobiles, or motorcycles, or in connection therewith or with the sale thereof, or for free replacement under contract or guaranty. In case any of the tires, inner tubes, parts, or accessories sold hereunder are diverted from this use, the purchaser will account for such tires, inner tubes, parts, or accessories to........ ...., the manufacturer thereof, at least once during each calendar year and will pay the tax thereon to him at the time such accounting is made.

Signed............

If it is impracticable to furnish a certificate for each order a certificate covering all orders between given dates (such period not to exceed a month) will be acceptable. If in any case such an order and certificate cannot be produced on demand of any authorized agent of the department the tax in respect to the sale will be considered in default.

Substitute in place of the next to last sentence of Article 15 of Regulations 47, which reads as follows:

"A chassis is a part of an automobile and taxable at the rate of 5 per cent when sold separately regardless of whether it is a chassis for an automobile truck or wagon or for any other kind of automobile."

"A chassis provided with a superstructure of such design that it is without substantial additions adaptable for hauling heavy loads is an automobile truck or automobile wagon and taxable at the rate of 3 per cent. A chassis not so equipped is an 'other automobile' taxable at the rate of 5 per cent. Unless the manufacturer has actual knowledge that the chassis is to be used as an automobile truck, or automobile wagon, or has in his possession at the time the chassis is shipped or sold (whichever is prior) an order or contract of sale with a certificate of the purchaser in writing, printed thereon, or permanently attached thereto showing that the chassis specified in the order is to be so used, the tax shall be 5 per cent upon the manufacturer's selling price."

Article 34 of Regulations No. 47, entitled "Manufacturer also Retailer" is supplemented by adding a new paragraph to read as follows:

"In cases where it is impracticable to compute the tax in respect to articles sold at retail on the average wholesale price for which like articles were sold during the previous calendar month, the taxpayer has the option of basing the tax upon the ordinary or regular wholesale price for which like articles were sold during the previous calendar month."

BULLETIN

The Indianapolis Speedway 500-Mile race May 30th was won with a Fedders stock Radiator on Howard Wilcox's Peugeot Car.

Individual Cellular Tubes

An Exclusive Feature of this Fedders Radiator

Damaged radiators may be repaired by a novice; simply remove and renew injured tubes.

INFRINGEMENT NOTICE: This radiator is fully covered by patents and we will vigorously defend our rights against its unauthorized manufacture, sale or use.

These cell-like single tubes are an exclusive feature of the Fedders Genuine Honeycomb Radiator—and the very foundation upon which the success of this type radiator is based.

Fedders Radiators built of these **individual tubes** should not be confused with any of the various **ribbon types** made of sheets rolled and joined together to look like Fedders Individual Tube construction—the original of its kind, and the one with which we won our present Supremacy in the radiator field.

The core of this Radiator is built up wholly of these tubes placed in a horizontal position and anchored to the adjoining tubes by all **six flat surfaces** at their expanded ends, to form circulating water spaces around and between the tubes, not merely thin line edges or points of contact as with other radiators made to resemble this in outward appearance.

As a result of **genuine tube** construction, this Fedders Radiator has no equal in Cooling Efficiency, Ease of Repair, Resistance to Overheating, Freezing or Leakage.

Let us send full descriptive information

Some Immediate Problems

Engineering Comment on Pertinent Questions of Design

A NUMBER of engineers were asked by AUTOMOTIVE INDUSTRIES to write their opinions of certain features of design for automobile, truck and tractor control for the Engineering Issue. The comment was directed by questions which are printed with this article. The replies are an indication of the trend of opinion on these topics. You will find them interesting.

IF you could sit at luncheon with a dozen prominent engineers in the automotive industry and participate in the round-table discussion which would ensue, you could not fail to come away with many thoughts and perhaps a few inspirations. The status of the industry makes the views of engineers of the highest importance at this time.

In the following pages AUTOMOTIVE INDUSTRIES is presenting to you the approximate results of just such a conversation. The problems discussed are uppermost in the minds of automobile, truck and tractor manufacturers. We all realize that we are on the eve of many departures from what has been regarded as standard practice in the past. Changes, which on the surface appear radical, but which are really the fruits of development extending through several years, are about to be made. Never were the inventors, designers and engineers so busy in boldly carrying out principles which have been evolved in the laboratory, but which have not as yet been put into practice.

A War Benefit

It took the war to jog us out of a mechanical rut. The quality of workmanship in the automotive industry has gone up, due to the experience gained in the manufacture of airplanes, airplane engines and parts requiring closer degrees of inspection than anything we have ever had to do with in commercial work. The demands of the government inspectors, which appeared unreasonable in many instances, have acted as a spur toward more accurate manufacture.

The entire automotive industry is focused around the power plant. It is the development of the internal combustion engine in small units which has created this rapidly growing industry. Refinements which perfect the engine, increase the efficiency of the products of the industry and consequently are of the utmost importance to all engineers. It is not strange, therefore, that when engineers get together one of their prime considerations is the power plant. Many new things are developing in automotive engines.

The fuel situation has made it imperative that we must operate at higher thermal efficiency than the 15 to 20 per cent with which we have been content during the past decade. Some believe that the superinduction engine points the way toward higher thermal efficiency, but a reading of the views of other engineers shows that this opinion is by no means unanimous.

Is it possible to secure a much greater efficiency from an engine of definite size by ramming an excess charge into the combustion chamber so that the filling will not be 75 or 80 per cent, but, instead, will be possibly 105 or 110 per cent at the beginning of the stroke?

There are many possibilities in the future for piston developments. Nowhere else is there such a variety of opinion to be found. The question of the aluminum or

cast-iron piston, which we have been struggling with for 4 years, has not as yet been definitely answered. The questions which will be answered only by the future include whether or not the coming piston will be something along the lines of the hour-glass type or some other form of non-continuous wall, or whether it will be along the lines of the full cylindrical type. The Riccardo type of piston, which has both a guiding and a sealing element, has created an unusual amount of interest.

Aluminum pistons are being made by different makers for different purposes. Some are using aluminum because it is light, and these make their sections as light as is structurally possible, in order to cut down the reciprocating masses in the engine. Others use aluminum because it is an excellent conductor of heat, and these, in order to get the heat away from the center of the piston as rapidly as possible, use heavy section aluminum pistons, which weigh practically the same as those of cast iron.

How to get endurance and long life from the tractor engine has been a subject which is far from being exhausted. The engine builders are divided into two schools. One designs the engine to get all the power possible from a given displacement; the other designs the engine with restricted intake passages to automatically prevent the engine from being overworked.

Lubrication

Another important development in the tractor engine is the question of lubrication. A short time ago we were of the opinion that pressure lubrication was the only system for the tractor engine. That this opinion is by no means universal will be perceived from the discussion in these pages and conversation with various tractor engineers. The opportunity for allowing the oil to settle, produced by the splash system of lubrication, is important according to some, while others believe that the only way a tractor engine should be lubricated is by oil positively fed to all spots under high pressure.

Some of us who have watched performances on kerosene and have witnessed results which are far from satisfactory are wondering if it would not be better to discontinue the kerosene pretense and come out flat-footedly on a frankly gasoline basis. Some tractor engineers are thinking the same thing, but not all of them. Some believe that the few cents saved in fuel is more than made up by the amount spent in replacing lubricating oil and in repairing the damage due to the destruction of the oil film. The increased crankcase dilution due to the use of kerosene is believed by many to more than pay for the fuel price difference.

Trucks, passenger cars and tractors are all presenting transmission problems which are keeping engineers awake at night. In the passenger car field practically everyone is dissatisfied with the modern selective transmission, particularly as regards its noise on first and second speeds. The question is, can the present type of gearbox be improved so as to give the desired silence by superior design and workmanship, or is it necessary to go to some other type, which may perhaps be a radical departure from that in use.

There has been much criticism that the weight of rear axles, both of passenger cars and trucks, is too great. It has been often asked by engineers if it is not possible to materially reduce the axle weight by superior design. Little change has been made in the axle in recent years and the impression prevails that this point has not been fully taken care of. This is a big field for useful discussion.

Braking System

In no other matter is the opinion of engineers so unanimous as it is in regard to brakes. There is not an engineer who does not say that, taken as a whole, the brakes on American cars and trucks are inadequate. You cannot drive any American-made car or truck from Philadelphia to Pittsburgh over the Lincoln Highway and use the brakes like they should be used. The engine must be used as a brake in order to help out the inadequate system on the drum. This is not denied by any engineers with whom we have had an exchange of views. What are we going to do about it? This is a most important matter and one which should be taken care of immediately. Is the transmission brake the answer?

What do engineers think of the transmission brake as a hand brake possibility, thereby removing the linkage from the rear axle and also providing an independent drum not subject to the heat generated by the application of the foot brake? This, of course, gives a brake which would perhaps be more satisfactory to continuous hill work, but objections are advanced in the way of chatter, of excessive strains on the universals, and, where metal to metal brakes are used, of the extreme noisiness.

The Engineers' Forum

These problems, and others, are of such importance that the time has come for us to lay our cards on the table and throw the suggestions, which we all have, into the common melting pot, to evolve the answer. These problems are not going to be solved by any one individual or by any firm. The industry, as a whole, is going to be advanced as soon as they are solved and American-made products are going to increase their reputation throughout the world at a rate governed by the manner in which we handle these vital questions which now confront us. AUTOMOTIVE INDUSTRIES maintains an open forum in its pages and engineers are invited to discuss pertinent problems through its columns. In the following pages are given some of the opinions of leading engineers on the matters outlined in the foregoing.

As to the Automobile and Truck

By D. McCall White

I believe there is much to be said for superinduction for the purpose of ramming an excess charge into the combustion chamber, thereby increasing the volumetric efficiency, etc. This will, however, have to be accomplished in quite a different manner than in the devices I have seen. There are instances where crankcase compression has been used for this purpose and this appears to me to be quite an ideal way of doing the job, except for the fact that the entrance and exit of the air causes a considerable shuddering noise, which is very objectionable. Where supercharging is used, the means taken for injecting this charge into the cylinder must be such as to accomplish its purpose without objectionable noise.

On the matter of the future of piston development the hour-glass is a type of piston which I developed in England and which was in a measure successful. The only unfortunate thing about this is that, in view of the fact that reciprocating gases must be as light as possible, the pistons must be made short. In designing the hour-glass

THE QUESTIONS

THE views of representative engineers given on these pages are in answer to the following definite questions:

Passenger Car and Truck Questions

1—Do you believe in superinduction charges for the purpose of ramming an excess charge in the combustion chamber, thereby increasing the volumetric efficiency and consequently mean effective pressure?

2—What do you think of the future of piston development? Is it coming along the lines of the hour-glass type of pistons or some form of non-continuous wall, or do you believe that the full cylindrical type will prevail?

3—What do you think of the heavy type of aluminum piston as a possibility; also. what do you believe of the die cast aluminum pistons, perhaps used in certain such types as the Riccardo with a guiding element and a sealing element?

4—Do you believe there is any chance for a radical change in transmissions, getting away from the noisy performance on second and first speeds? What do you believe will be done to combat this noise in ordinary transmissions?

5—Do you think that rear axles are too heavy for the power transmitted? Will it be possible by superior design to greatly improve the rear axles?

6—What do you think of the transmission brake as a hand brake possibility, thereby removing the linkage from the rear axle, and also providing an independent drum not subject to the heat generated by the application of the foot brake; also, giving a brake which would be a true emergency brake and useful for continuous hill work?

Tractor Questions

1—What do you think of governing tractor engine performance by restricted intake passages.

2—What do you think of the splash vs. pressure lubricating question for tractor engines?

3—Do you think it would be better to sell tractors on a frankly gasoline instead of kerosene basis?

type, one is apt to cut out too much surface. There is no doubt that the hour-glass type is a very stiff piston, but I believe that the full cylindrical type of piston will eventually prevail, because it has a maximum amount of surface, which is the best preventive against condensation getting past the piston walls and down into the crankcase. Likewise, it also forms the best possible seal to prevent the oil from passing upward into the combustion chamber.

Aluminum pistons I do not regard as a possibility under present circumstances, owing to the great amount of change in shape due to temperature. It may be possible to design a piston having a light cast-iron shell, with an aluminum head to carry away the heat, and this probably would be a good deal better than a complete aluminum piston.

Transmission Brakes

I believe there is a radical change coming in transmissions. This change will take the form of the epicyclic gear, electric transmission, chain transmission, or some other type differing from the designs in use. Likewise, in rear axles a change is coming. As they are designed at present, they are entirely too heavy for the power transmitted. By careful and scientific design I am certain that the rear axle can be greatly improved.

Transmission brakes have many things in their favor, and, likewise, against them. I have had a good many years' experience with transmission brakes, not only as a service proposition, but also as emergency brakes. In its favor it may be said that it has a great deal of power. However, the velocity of the drum itself is very great and rapid wear on the asbestos lining is sure to take place. If cast iron is used, there is sure to be much noise. Brake chatter is also very prevalent with the transmission brake, but there is no doubt that all of these things can be overcome by careful design and the matter is well worth careful investigation.—D. McCall White, Former Vice-President Cadillac Motor Car Co.

By E. Planche

It is, in my opinion, of paramount importance to completely fill the cylinders with the best explosive mixture during the complete range of speeds of the motor, especially since the general use of the heavy gasolines which have been furnished to the public in the last few years. This question has had my careful attention during the last 6 years and all motors I have designed during that period have had a specially designed inlet pipe, of conical shape, inside the cylinder block, thereby increasing the speed of the gases. I have also brought the carbureter as

A New Method of Determining Rate of Flame Propagation

Originated by Dr. Donald MacKenzie of the Bureau of Standards and Successfully Applied to a Single-Cylinder Liberty Engine

By P. M. Heldt

ONE of the most interesting questions connected with the internal-combustion engine is that regarding the rate at which the flame or explosive wave is propagated from the point of ignition to the more remote parts of the combustion chamber. The term "rate of flame propagation" has been much used, especially in glib talks on the efficiency of different types of ignition apparatus, but it must be admitted that our knowledge on the subject so far has been exceedingly limited. It is true that a number of experiments have been made, but in practically every instance the explosion took place in a closed vessel, so that the effects of turbulence of the mixture and change in volume of the chamber were not brought out.

Just now the question of flame propagation is of peculiar interest, because of its bearing on the subject of knocking in engines. Various theories as to the causes of knocking have been advanced, and it has been impossible to check them because of imperfect knowledge of exactly what occurs in a cylinder after the spark has passed at the plug.

Principle of New Method

Dr. Donald MacKenzie of the Bureau of Standards has evolved a new method of measuring the rate of flame propagation which is based on the principle that when the atmosphere surrounding a pair of spark terminals is flame, the electrical pressure required to break down the resistance of the gap is reduced. Thus, if there is an extra, inactive spark plug in the combustion chamber, the spark terminals of which are subjected to a voltage which is just short of creating a spark when the gap is under the normal compression pressure, then as soon as the flame reaches the gap ionization takes place; that is, there is a transfer of electricity from one electrode to the other. By passing both the sparking current and the discharge across the terminals of the inactive spark plug through the coil of an oscillograph, wave diagrams of both of these discharges can be recorded on the same sensitive plate. If, in addition, the sine curve of an alternating current from service mains of known periodicity is recorded on the plate, an accurate time scale is automatically obtained, and the time it took for the flame to travel from the working to the inactive plug can be readily measured.

Experiments are being conducted on a single-cylinder Liberty engine which is set up in a temporary structure at the Bureau of Standards. The work is being done by Dr. MacKenzie and R. K. Honaman, who in a recent paper before the American Physical Society at Washington gave a description of the set-up employed and an outline of their plans.

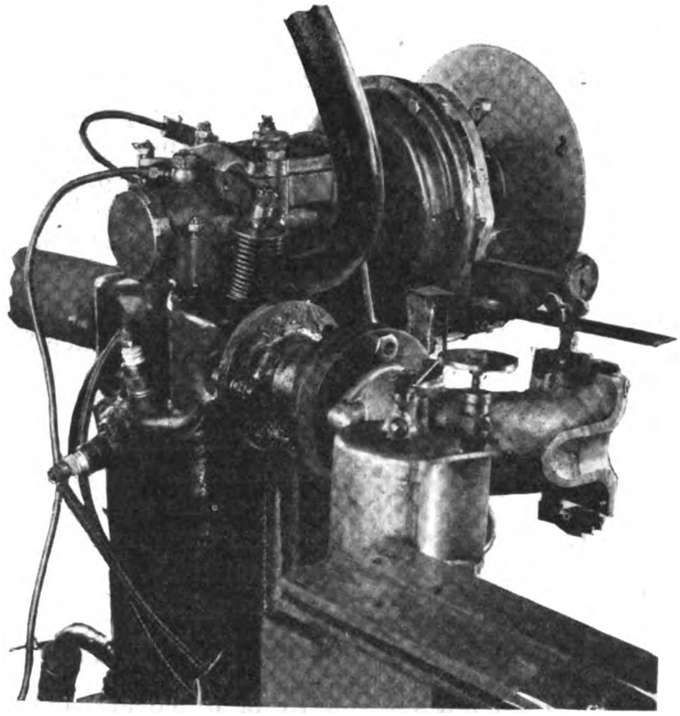

Fig. 1—Single-cylinder Liberty engine used in experiments to determine rate of flame propagation

A photograph of the Liberty single-cylinder engine used in the experiments is reproduced (Fig. 1). As is well known, the standard Liberty cylinder has two spark plug bosses, both in the cylinder head, in the corners between the valve pockets. In this particular cylinder a third spark plug boss has been provided at the side of the combustion chamber. The spark plug in the last-mentioned boss is used for ignition, while the two other spark plugs are used for observations on flame propagation.

In Fig. 2 is shown a diagram of the electrical connections. To obtain the high voltage required at the terminals of the inactive spark plugs, use is made of a transformer by means of which alternating current from service mains is stepped up from 100 to 5000 volts. Both terminals of the secondary of this transformer are connected to Kenetron tubes, or vacuum tube valves. For the benefit of those not familiar with this type of electrical device, it may be explained that a Kenetron valve is a vacuum tube containing two electrodes, one in the form of a disc and the other in the form of a coiled filament, which can be brought to incandescence by current from a low-voltage battery. The battery circuit is closed through the filament and the complete device is then included in the alternating-current circuit, one alternating lead being connected to the filament electrode and the other to the disc electrode. During that part of the cycle when the hot electrode is negative, electrons, or

small particles of negative electricity, are projected from it toward the cold, positive electrode, these electrons forming current carriers. There is no corresponding action during the other half of the cycle, when the hot electrode is positive. Hence, only impulses in one direction pass through the vacuum tube.

The unidirectional high electromotive force obtained from the transformer, through the vacuum tube valves, is used to charge two condensers, C^1 and C^2, through high resistances R^1 and R^2. Toward the end of the compression stroke, a moment before the spark passes at spark plug No. 1, condensers C^1 and C^2 are electrically connected to the central terminals of spark plugs Nos. 2 and 3 respectively, by means of a contact disk which is mounted on the overhead camshaft (and which can be seen in Fig. 1). Thus, when the spark passes at plug No. 1, plugs Nos. 2 and 3 are subject to a static pressure of about 3000 volts. As soon as the flame of the explosion reaches the gap of spark plug No. 2 ionization takes place and the condenser connected to this plug will discharge. By tracing out the connections it will be seen that the discharge current has to pass through the oscillograph vibrator. The same thing is repeated a moment later at plug No. 3.

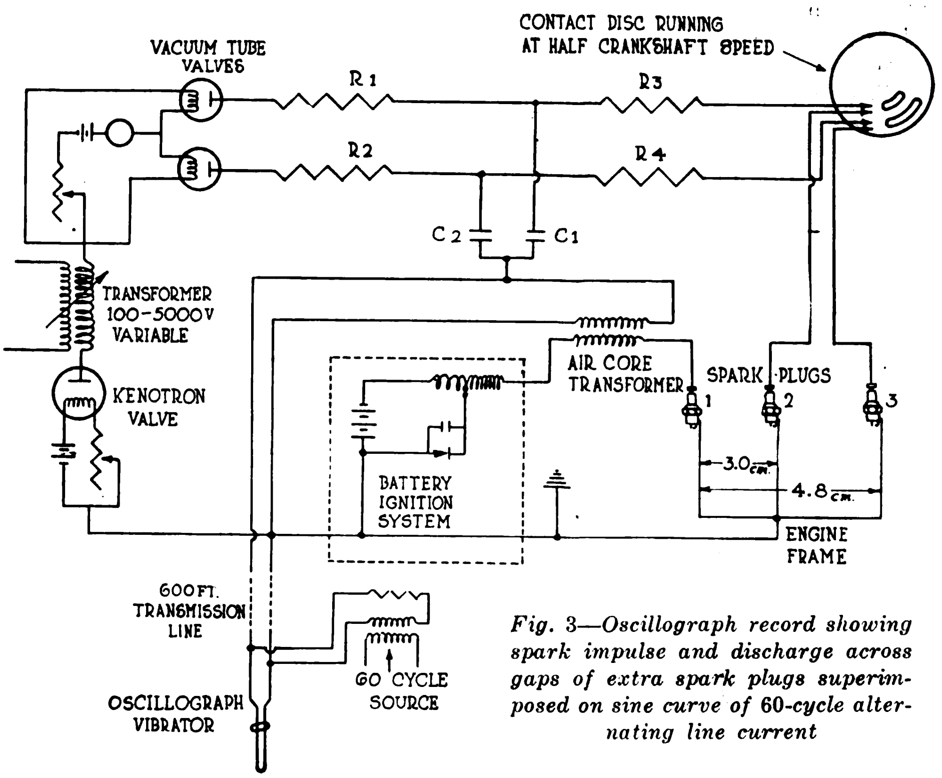

Fig. 3—Oscillograph record showing spark impulse and discharge across gaps of extra spark plugs superimposed on sine curve of 60-cycle alternating line current

The regular battery ignition system is used for igniting the single-cylinder engine, the secondary terminal of the ignition coil being connected to spark plug No. 1, at the side of the combustion chamber, through the primary of an air core transformer. The secondary winding of this air core transformer is connected in circuit with the oscillograph. This instrument is located in another building, and connection to it is made through a 600-ft. transmission line. A 60-cycle alternating current is also sent through the oscillograph, and this traces a sine curve on the oscillograph plate, which serves to determine the time scale.

Character of Oscillographic Record

The effect obtained on the oscillograph plate, therefore, is as follows: A continuous sine wave is traced by the current from the 60-cycle source. When the spark occurs at plug No. 1, an impulse is induced in the secondary of the air core transformer, and this produces a corresponding impulse of the oscillograph vibrator, which is superimposed upon the sine curve. A moment later, as the explosive wave reaches the gap of spark plug No. 2, condenser C^1 discharges through this plug, and since the discharge passes through the oscillograph, the record of this sudden current impulse is also superimposed upon the sine curve. The same phenomenon is repeated a moment later when the explosive wave reaches the gap of spark plug No. 3.

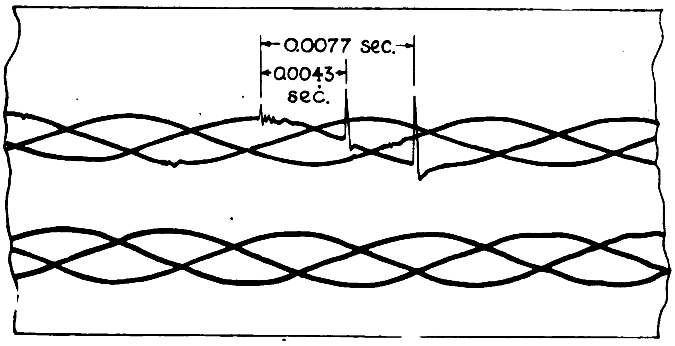

Fig. 2—Diagram of electrical circuits

Some of the details of the electrical circuit require further explanation. There might be a question as to the need of the contact disk at the end of the camshaft, as the open circuit at the spark plug should prevent a discharge of the condenser taking place. It was found that in order to make the apparatus most effective, the voltage applied to the spark plugs must be not far short of that required to produce a disruptive discharge under full compression. Such a pressure on the spark plugs, however, would cause a spark to pass at the beginning of the compression stroke, when there is little compression in the cylinders. Hence, the contact disk is needed.

An expedient resorted to in order to obtain as sharp a signal as possible upon the arrival of the explosive wave at the inactive spark plug consists in making the values of the resistances R^1 and R^2 from 40 to 50 times as large as those of resistances R^3 and R^4. This minimizes the current from the vacuum tube valve flowing through the spark plug circuit, while, on the other hand, the low value of resistances R^3 and R^4 allows a rapid discharge of the condensers through the spark plugs. Also, the charging of the condensers from the transformer through the valves is distributed over a comparatively long time. The actual values of the resistances are 15,000 ohms for R^3 and R^4 and 600,000 ohms for R^1 and R^2. The two condensers C^1 and C^2, which have a capacity of 0.0034 microfarad each, are charged to a potential of about 3000 volts. This results in an initial discharge current of about 0.1 ampere and gives a deflection of the oscillograph vibrator of 20 mm. (0.8 in.). On the other hand, the maximum rate at which charge enters the condensers is only about one-twentieth of this.

It will be noted from Fig. 3 that three Kenetron valves are used, one on one side of the transformer secondary and the other two on the opposite side, in parallel. Valves B^1 and B^2 are required only because if resist-

ances R' and R² were both directly connected to the secondary of the transformer, current from condenser C² would discharge through R¹, R² and R³ into spark plug No. 2, so that the potential of C² would be greatly reduced before the flame reached plug No. 3, and no discharge would take place across the gap of this plug. Valves B¹ and B² allow charging to take place freely, but prevent an interaction of the two discharging circuits.

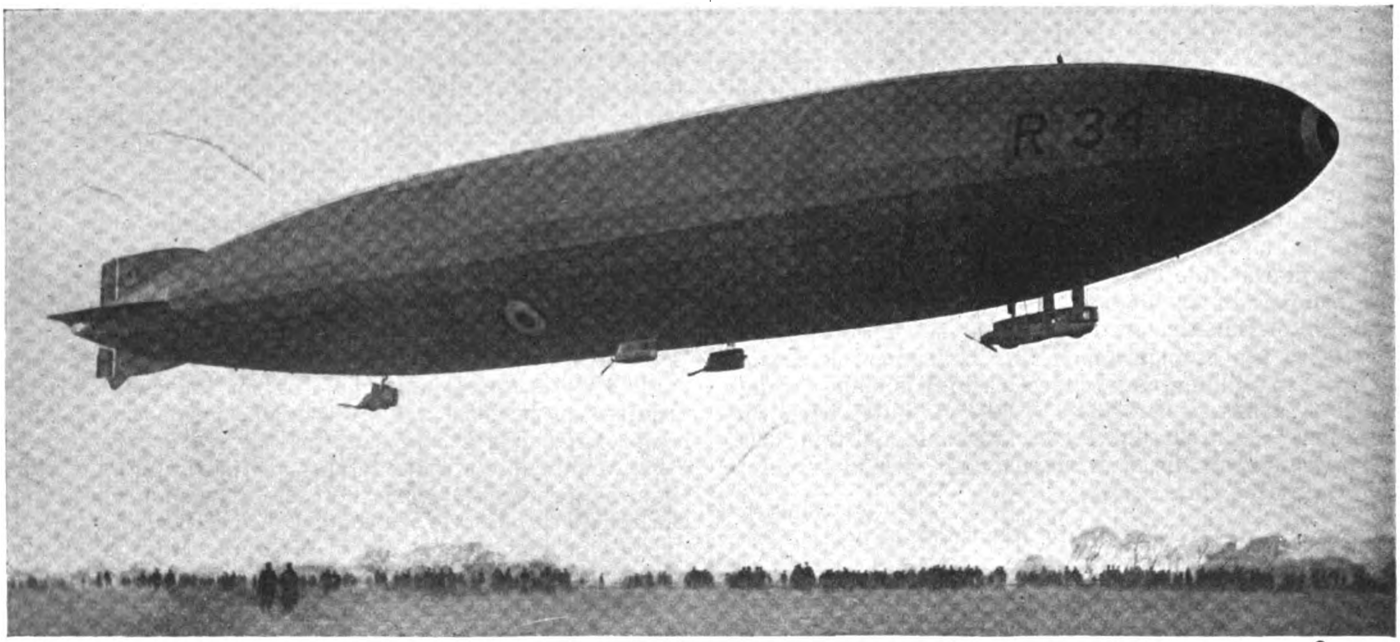
A somewhat puzzling feature of Fig. 3 is that there are 3 sine waves on the slide. The reason for this is that the shutter of the oscillograph was held open for three successive revolutions of the drum. The equal phase relation of the three curves was obtained by properly adjusting the speed of the drum.

It will be noted that the ignition spark is indicated on the oscillograph by a number of successive pulsations. This curve, of course, is no direct record of the spark, but a curve of its first derivative, as it is the secondary current from the air core transformer that produces the record on the plate.

As noted in the diagram, Fig. 2, the distance between spark plugs Nos. 1 and 2 is 3 cm., and the distance between Nos. 1 and 3, 4.8 cm. Fig. 3 shows that under the particular conditions of operation under which this oscillogram was obtained it took the flame 0.0043 second to travel the first-mentioned distance, and 0.0077 second to travel from plug 1 to plug 3. Measurements taken on different films have shown that the rate of flame propagation varies greatly with the conditions under which the engine is operated. Some of the factors affecting it are the richness of the mixture, the compression ratio, the heat content of the ignition spark, and the degree of turbulence within the combustion chamber. It was found in all cases that the velocity of flame propagation increased with the distance from the ignition plug. For the first 3 cm. (the distance between the ignition and the nearest inactive plug) the values varied between 5 and 25 meters per second, and for the first 12 cm. (the distance between plugs 1 and 3) it varied all the way from 15 and 60 meters per second.

The practicability of the method having thus been established, it is planned to carry out a complete series of tests to determine the effect upon the rate of flame propagation of all the different factors, such as mixture, composition, degree of compression, spark advance, intensity of ignition spark, grade of fuel used, etc.

Measurements and Tests of the British R-34



RECENT cable messages tell of an unusual test sustained by the British airship which is expected to start a trip across the Atlantic in the near future. This test flight was not planned, but was the result of the dirigible becoming lost in a fog and being in the air 21 hours and returning to her hangar under her own power.

"R-34 was built for the British Admiralty at the Airship Works of Wm. Beardmore & Co., Ltd., Inchinnan, Renfrewshire, Scotland, and the photo shows the vessel in the air prior to carrying out a successful trial flight on March 15. The ship is about 650 ft. long by 80 ft. in diameter, and it has a capacity of more than 2,000,000 cubic feet, with a useful lift of over 30 tons. She is fitted with Sunbeam engines and capable of attaining a speed of about 70 miles per hour. The preliminary trial extended over a period of 4½ hours under favorable weather conditions and the ship flew at various altitudes up to 2,000 feet. The ship's complement numbered about 30, including several technical members of the Beardmore staff. "R-34" is a great improvement over the other dirigibles which the firm completed and delivered to the Admiralty during the War. The time occupied in the construction of this vessel, in her shed, was about 6 months.

"R-34," subsequent to her trial flight, completed with satisfaction an endurance non-stop flight of 19 hours, during which trial all kinds of weather were encountered, rain, fog, snow, mist and squalls, but the vessel was able to carry out her program of visiting Ireland and otherwise circling about the British Isles before returning to her large hangar at Inchinnan.

Sundry details are being carried out at the moment and it is expected that the British Admiralty will permit the vessel to start the voyage across the Atlantic at an early date. The vessel has been fitted with fuel tanks of sufficient capacity to enable the journey to be effected easily, and she also possesses all other necessary requirements.

Carburetion of Low Grade Fuels

Some Points on the Design of Inlet Manifolds for Heavy Fuel Engines—Easy Bends vs. Chokes at Crotches

By O. H. Ensign

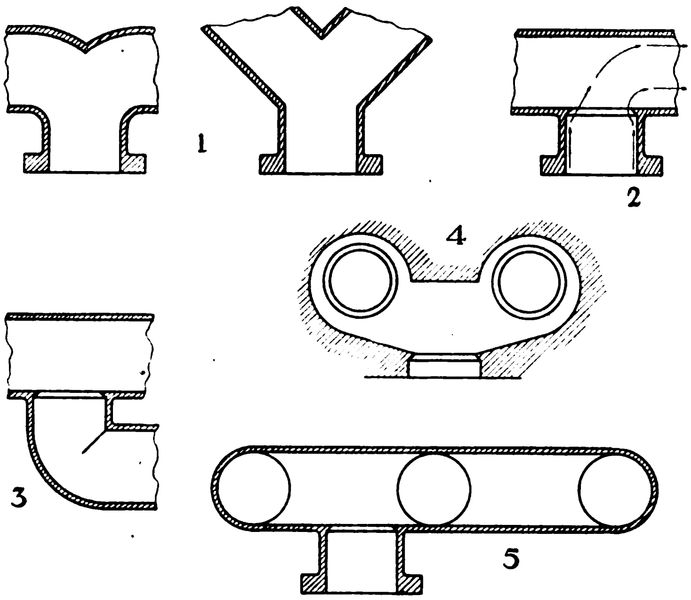
ONE of the most difficult problems in connection with the present fuel situation is the correct design of manifolds. Most of the existing automotive apparatus has been designed around the requirements of an easily vaporized fuel. Such a fuel approximates in performance a mixture of air and fixed gas, and in the design of manifolds it is necessary only to consider the fluid friction of the mixture and the absolute pressure loss involved in the change of direction at branches and Y's. But modern gasoline has an initial boiling point as high as 150 deg. and an end point as high as 450 deg., which calls for an entirely different solution of the problem, and this remark applies all the more strongly to any efforts to burn kerosene or distillates between kerosene and our so-called gasoline.

We are compelled to consider the practical use of a so-called wet mixture, for as soon as we get into the realm of the perfectly dry mixture, the size of the engine, its weight and expense rise rapidly; so the attack of the problem must be along the line of making the best use of a mixture, which involves utilizing the lighter bodies of the fuel with enough heat to make sure of good ignition and flame propagation, and of carrying the heavier constituents into the engine cylinder, finely enough divided and homogeneously distributed through the mass of mixture to give correct or reasonably correct combustion. In other words, to vaporize a portion by the use of vacuum and heat, and by turbulence and agitation, continued right down to the opening of the valve, to mechanically handle the heavier elements in such a manner as to bring about the above result.

It has been demonstrated that when a well vaporized mixture passes through an elbow there is always considerable condensation. Therefore, beyond every elbow and at every turn or branch, the mixture should be violently agitated, because poor distribution to the various cylinders and lack of homogeneity of the mixture in any cylinder may be easily demonstrated to be much greater causes of power than the friction involved in the following constructions.

Y branches such as shown in Fig. 1 are decidedly wrong for low grade fuels. Assume the mixture approaching such a Y branch with the fuel uniformly distributed throughout the stream of air; when coming to the Y, the fuel being denser than the air, part of it that should go to the right, will pass right on and fall dead in the quiet air to the left, being deflected by the "splitter." This fuel is picked up by the next impulse to the left, with the result of a puff of black smoke from the exhaust after it has reached the cylinder. In order that all cylinders may get sufficient fuel for each explosive impulse, the mixture must be made richer, because, as above described, a portion of it is separated from the air into relatively large drops and is not available as explosive fuel.

The proper construction for a branch is shown in Fig. 2. The arrows show how the fuel flows with the air in the right direction. The fuel in the air stream nearest



INTAKE MANIFOLDS—1, Ordinary manifold joints with "splitters" (defective). 2, Proposed design of manifold. 3, Elbow with sharp inner edge. 4, Siamesed valve passage. 5, Recommended design of triple outlet manifold

the side calling for it is thrown into the center of the stream, and that from the opposite side is deflected in the right direction. There is excessive turbulence at such a branch, not easily shown by arrows, and remixing occurs. Also there is always more or less of the heavier fractions on the walls, in liquid form, and with this construction these globules are thrown out into the air stream again and remixed. Fig. 3 illustrates the construction which should be followed in passing an elbow; the inner edge should always be sharp. As mentioned above, the mixture in passing around an elbow is separated more or less from the air stream. Immediately beyond the elbow there should be a sharp edge choke that will tend to throw this fuel back into the air stream. Fig. 4 represents the ideal construction for connection to siamesed valve pockets. Here again we have a branch, but by setting the wall opposite the entrance so that it is about on the center line with the two intake valves, we obtain an increase in flexibility, power and economy, for in this case the fuel mixture is properly maintained until it enters the cylinder, upon entering which it is again broken up and finally delivered in the form in which it will develop the maximum mean effective pressure.

There is a great variety of manifold designs for connecting up three or six cylinders. Fig. 5, laid out in detail as explained above, will give by far the best results and is the simplest form possible. The writer has

Study of Air Resistance and Air Flow

Laws of Air Resistance Determined for a Wide Range of Air Speeds—Eddies Produced by Obstacles—Practical Applications to Aircraft and Automobile Problems

By H. Levy, M.A., D.Sc., F.R.S.E.*

THE problem of the forces brought into play by the motion of a body through the air at rest, or, what is in many respects identical, by the steady motion of air past a body at rest, is one which, although it has sprung into importance during recent years on account of the rapid development of aerial flight, is of no small consequence in other branches of engineering. The question has long been recognized as one which vitally affects such questions, for example, as the design of bridges and light buildings exposed to the forces of winds and gales. On the other hand, automobile engineering design, in common with other branches of locomotion, fighting as it is for the last inch in efficiency, cannot afford to neglect the effect of wind resistance to its motion and modifications that might be introduced into design, both to reduce this parasitic force and to minimize the effect of the associated evils of dust raising.

These are only a few of the branches of engineering to which the question should appeal with cogency, but it will become apparent that the question of air flow is not alone applicable merely to the motion of bodies in air, but is exactly equivalent to the corresponding problem of motion of bodies through water. There are at once, therefore, opened up whole fields of marine engineering on which an analysis of the problems of fluid flow will throw light.

In illustration, the exact contour of the hull and shells of sea craft of all descriptions, including submarines, torpedoes, etc., cannot possibly be accurately determined without a thorough knowledge of the forces due to the interaction between the body and the fluid, while the magnitude and directions of these forces are determined entirely by the nature of the flow set up by the body in its neighborhood.

Understanding of Medium First Essential

Before coming to a detailed study of the disturbance set up by a body in its motion and the resistance experienced, it is necessary to understand clearly the properties of the medium, air, upon which the whole phenomena depend. Although for the moment we restrict ourselves to a gas, the parallel with a liquid—water in general—will be brought out shortly.

It is an accepted fact that any volume of air is ultimately composed of an immense number of discrete molecules, flying about in all directions, each molecule possessing its own mass and velocity. By the impact of these molecules against the side of any vessel containing it, or against the surface of any body immersed in the gas, a pressure is originated whose magnitude at any point may be measured by the change of momentum experienced per second, perpendicular to the surface, by the molecules impinging on unit area. That is to say, we may conceive the body as being a man bombarded on all sides, and at every point of him, by footballs, so that the pressure he will experience will depend on the change in velocity of these balls on the rebound. The pressure thus originated may be regarded as a static pressure which exists even when the body is at rest and is what is commonly recognized, in the case of a liquid, as the hydrostatic pressure. An extra complication arises, however, if the body be in motion, for the particles of gas impinging upon it will not otherwise come into being.

In essence, the distinction between the two cases is equivalent to that which occurs where a football strikes a foot at rest, and where the football is deliberately kicked. The pressure on the foot in the latter case will in general be greater. On the surface of the moving body therefore an additional pressure—it may even be a diminished pressure if the foot be moving away from the ball on impact—will be experienced at each point, frequently referred to as the dynamic pressure.

Skin Friction

If the effect of the body, however, were merely to cause a change in momentum perpendicular to the surface, many of the complications that arise in aerodynamic and hydrodynamic analysis would be removed, but an additional trouble arises due to the fact that at the surface of the body there is a distinct tractive effect, some of the molecules of the gas becoming involved in the molecules of the surface of the body, with the result that the latter continually drags in its neighborhood a layer of the gas it would otherwise throw off. There is originated as a consequence a surface dragging force recognized under the more common name of skin friction. To this, however, we shall return shortly.

Before it is possible to proceed further, it is necessary to extract from this exceedingly complex state of affairs the properties of the gas which can be recognized as vital for determining the phenomena.

To trace out and sum up the effects of the impacts of the individual molecules, is clearly impossible. But this continual sweeping of the particles to and fro in all directions produces in the gas as a whole three distinctive properties which if once postulated may be regarded as defining the medium. The question will be approached by regarding the sum of the effects due to the rapid series of impacts really as an average effect.

The particles at any instant enclosed in any small region have each their own velocities, but there will, however, exist over the region an average velocity, average both in magnitude and direction. Each molecule possesses its own distinctive mass, but the total mass in a unit volume can be considered as the density of the gas at that point, and on this will depend the amount of momentum which can be communicated to it

*Professor Levy is in charge of the wind-tunnel investigations for the National Physical Laboratory of Great Britain, which corresponds to the U. S. Bureau of Standards. He is the author of some of the best technical books on aviation.

by impact with the body, either directly or indirectly through the medium of other masses of gas. Density therefore is the first property we must lay down.

The next property will depend on the nature of the force exerted by one layer of the moving gas on its neighbor.

Suppose A and B be two adjacent layers of gas, both moving in the directions indicated by the arrows, the average velocity in A, however, being slightly greater than that in B. The molecules in A do not always remain there, but flying about in all directions some of them will become inveigled in the layer B, while at the same time an equal mass from B will become inveigled in the layer A. The result of this is that A increases the momentum of B, while the latter tends to decrease the momentum of A. There is, in fact, along the surface between the two layers a rate of change of momentum, or in other words the equivalent of a force. This applies to all regions of the gas in which there exists a variation of gradient and velocity, and this dragging force of the one layer on its neighbor is known as the force of viscosity. Viscosity, in fact, is the second and in many respects the most important property of the gas.

There is one remaining property which concerns us. By the application of an external force to any volume of the gas—it may even be by the forces originated within itself by its own motion—the volume may be decreased or compressed. It is clear that if this should take place to any appreciable extent, not only will energy be used up in the compression, that is to say, not merely will the resistance of the body causing the compression be increased, but the actual nature of the air flow may be fundamentally altered.

For the present purpose we need then to restrict ourselves only to these three principal properties: Air is dense; it is viscous; it is compressible.

Effect of Compressibility

Although, as far as the present discussion is concerned, air may be defined in terms of these three factors, and these three only, they are not all equally important in their effects on the resisting forces brought into play by the motion of a body in that medium. Experimentally it has been found that the stress to be laid upon each of them is largely a question of the speed of the body. During the war a large amount of aerodynamic analysis of this nature has been carried through, and one important fact in particular, recognized certainly to some extent before the war, has emerged. This is concerned with the extent to which compressibility affects the resistance. In Fig. 2 is shown a picture of the waves set up in air by the motion of a bullet. This has been obtained by using the fact that the refractive index for air varies with density, so that, as a consequence, if condensations or rare factions take place, these would show themselves on a photographic plate.

From this photograph it appears that compressibility waves of this nature are brought into being by bodies such as projectiles moving at exceedingly high speeds, but at moderate speeds these waves do not become apparent. It is clear that each of these waves contains a certain amount of energy which is being transmitted through the air, and originates from the body in its motion.

As a consequence, the resistance of the body would tend to increase at a much greater rate than it would otherwise do at those speeds at which these waves begin to make themselves evident. It would in fact appear that after a certain speed is attained, the effect of compressibility without which these waves could not originate becomes a very vital factor in the resistance.

If this critical speed lies anywhere in the region of the normal speed of flight for aircraft, compressibility is clearly a question which must be carefully scrutinized. If, however, as will be seen is the case, this critical speed is well above normal flight speed, no serious error may possibly be introduced by ignoring it, while the advantage of considerable simplification will be obtained.

Analysis of Shell Motion Valuable

Recent analysis of the motion of shells in gunnery has afforded just the evidence required, for here we have a body projected at an extraordinarily high speed and slowing down by the retardation of the atmosphere. If the resistance of the shell at each point of its path could be measured it could then at once be determined from a consideration of this resistance whether a critical speed of the type anticipated exists.

The results obtained have afforded a startling justification of the theory. At first sight it appears an extremely difficult problem to determine the resistance of a projectile varying as it does from point to point, but a simple analysis of the following nature gives accurate enough results. Shells of the same type are projected at the same initial velocity and elevation, passing all approximately along the same trajectory.

By altering the fuse setting the shells may be made to burst successively at different points of the path and the times taken between firing and bursting. From these the trajectory may be drawn and the time of arrival of the shell at each point marked upon it. It is then no difficult matter to obtain by graphical means the speed and deceleration of the shell at each point. The resisting force on the body is then easily estimated from the deceleration by the usual application of Newton's laws of motion. A chart can then be constructed showing the variation in resistance of the shell for the large range of speeds passed through in its motion, viz., approximately 2200 feet per second to 300 feet per second.

To illustrate the law of resistance and its dependence on speed, however, it is not necessary or even most instructive to plot resistance as ordinate. Numerous experiments have shown that most bodies, at normal speed, experience a resistance to flight approximately proportional to the square of the speed, and the divergence from this law can best be seen, not by plotting resistance against velocity, giving a curve approxi-

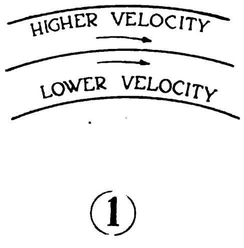

Fig. 1—Diagram to illustrate air viscosity

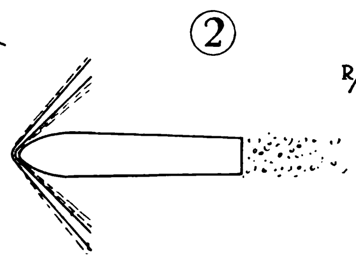

Fig. 2—Waves set up in air by motion of bullets

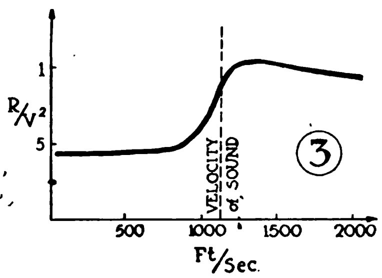

Fig. 3—Change of air resistance with air speed

mately parabolic, but rather resistance divided up by the square of the velocity giving approximately a straight horizontal line.

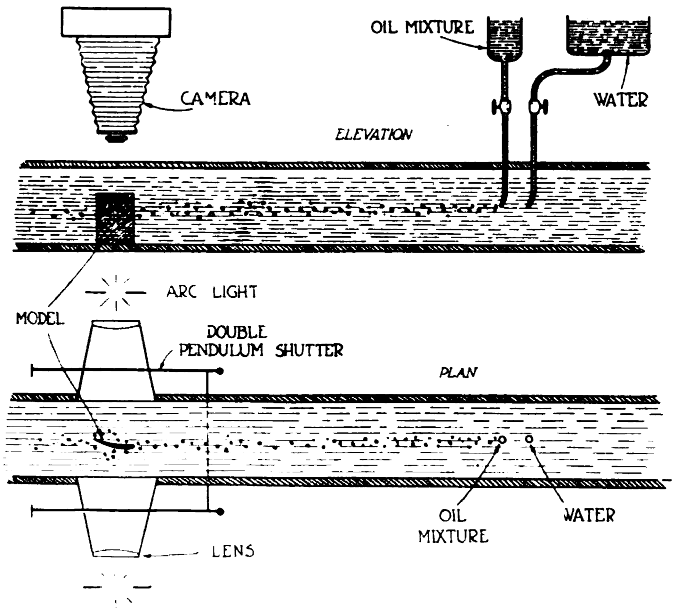
In the case under discussion therefore the most instructive manner of representation will be by plotting R/V^2 against V, where R = resistance and V = velocity. The chart obtained for the case of the projectile is then that shown in Fig. 3.

An examination of this curve indicates a rather remarkable phenomenon. It shows that up to speeds somewhat below the velocity of sound in air, up to say 500 ft. per second, the resistance is practically proportional to the square root of the velocity. In the region of the velocity of sound, resistance increases with great rapidity, evidently according to some much higher power than the square, and then, well above this critical speed, it tends to revert once more to the square law, although at a higher consant of proportionality than previously. This remarkable result fits in quite consistently with the considerations previously brought forward.

Well below the velocity of sound the body in its motion expends very little energy in the production of compression or sound waves. The resistance is almost entirely due to viscous forces. As it approaches the speed of sound, waves commence to be produced, traveling off ahead of the body at approximately 1100 ft. per second. When the body moves itself at this speed it rides on the crest of the waves, which it itself produces, while above this speed it cuts into undisturbed air, leaving its waves behind.

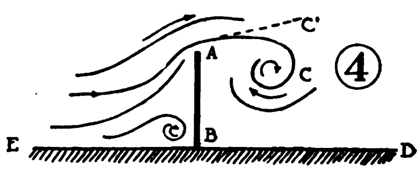
Incidentally, an interesting conclusion in gunnery may be at once deduced. For a body such as a shell or projectile which cleaves its way through the air at a speed well in excess of that of sound, a sharp pointed and tapering nose will clearly be most efficient, since by this means the energy lost in cutting through the medium would be reduced to a minimum, while the effect of the rear part of the shell must of necessity be of minor importance, since at these high speeds of flight where there is practically a vacuum behind the shell, the contour in that region cannot affect the nature of the air flow to any considerable extent.

From the point of view of the present discussion, however, where we are concerned with investigating the



Figs. 5 and 6—Plan and elevation of water channel for experimental determination of lines of flow

Fig. 4—Eddies produced by a flat plate perpendicular to line of motion



properties of air that are of importance in affecting the resistance at normal speeds of flight, an extremely important deduction follows from the foregoing conclusions, viz., that the property of compressibility upon which the production of sound waves depends may at normal speeds be completely ignored, and we are accordingly left with the simple fact that the whole problem for us depends purely on the density and the viscosity.

This conclusion immediately opens up to us an experimental method of handling these problems where otherwise grave difficulties would be experienced. To study the flow of air in the vicinity of a moving body, to determine where and how the eddying motion is produced and its effect on the resistance is extremely difficult in the case of air on account of its invisibility. But since, as has been shown, only density and viscosity are the important factors, while the air may be regarded as incompressible, we may have recourse to any other fluid which is dense, viscous and practically incompressible, provided the motion set up may be rendered visible and the exact law of comparison, the conditions under which deductions from the fluid to the air is clearly understood.

A substance satisfying these requirements is water, which is both dense and viscous and to all practical purposes incompressible. By a method shortly to be described it will be seen that the motion of the individual particles may be quite easily followed.

Consider what takes place in the neighborhood of a flat plate A B, Fig. 4, placed perpendicular to the direction of the streaming, whether of air or of water, E D being a wall. Such a case occurs, for example, with the wind screen of an automobile in motion, the blade of an oar moving in water, or the passage of a wind past a billboard or building.

Along A B the fluid is retarded in its motion, the stream line A C which just misses the edge would normally, in virtue of the inertia of the motion, be shot off along the direction of A C′. The particles of the fluid, however, in virtue of the retardation and viscous forces of the layers in their immediate neighborhood are reduced in motion and compelled to move along a path of smaller radius of curvature.

Similar causes continuously operating drag the particles further and further inwards, so that just beyond the edge a form of eddy or whirlpool is produced. It is a familiar enough experience to feel the back draught of this eddy on the rear seat of an omnibus or to produce the actual whirlpool as dimples on the surface of tea by gently drawing the tea spoon through the fluid.

Much of the dust raising due to the motion of a motor car along a road is undoubtedly caused by the particles of dust on the surface of the road being caught in these whirlpools as they are produced behind the car in its motion. Improvements in connection with these difficulties could undoubtedly be secured by simple modifications in designs, so arranged as to reduce this eddying to a minimum. Before this can be achieved, however, an accurate study of the conditions under which eddying is produced must be made.

The experimental method of analyzing the process that takes place during the flow past a body is exceedingly simple and interesting. An accurate study of the

problem demands a knowledge not merely of the lines of flow or stream lines past the body, but a measurement of the speed of the fluid at each point. This is necessary for numerous reasons but principally because from a knowledge of the distribution in velocity can be determined which regions of the fluid and which portions of the body are chiefly responsible for the dissipation of energy in the fluid and, therefore, for the production of resistance.

The experiment is conducted in a water channel $4\frac{1}{2}$ in. wide by 6 in. deep approximately and about 3 or 4 ft. long, fed continuously by water at a head sufficient to maintain the speed at about 1 in. per sec. For accurate work it is extremely important to keep either the speed or the dimensions low; in fact, to keep the product of the speed and breadth small, since when this quantity attains above a certain value it is impossible to obtain steady flow in the channel. This is consistent

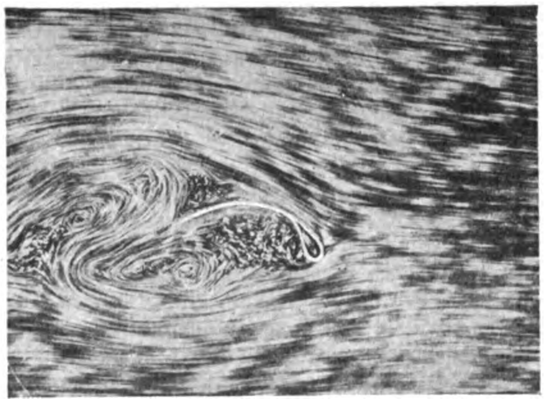


Fig. 4a—Flow of fluid past barriers

with the general statement that for all problems of flow past bodies there is a critical value of $v\,l$, where

v = speed of the body,
l = length of body,

above which the flow passes from one of uniform streaming to violent tubulence. This is equally true whether it be the flow through a pipe or channel or the streaming past an obstacle, but the corresponding value of $v\,l$ will be different in each case. It can be shown, in fact, to depend only on the shape of the body concerned. In the present instance where it is necessary to study the flow past the body, and as far as possible to eliminate the effect of the walls of the channel, it is exceedingly important to keep the value of $v\,l$ sufficiently low to be well below the critical for the channel itself. A rough indication of the principal features can be seen from the diagram, Figs. 5 and 6.

Details of Experiment

The light from the arc lights is projected by means of the cylindrical lenses as long, narrow beams onto the glass sides of the channel. This glass is blackened except for a narrow horizontal slit so that only a very narrow layer of the fluid in the channel in the neighborhood of the model gets illuminated, while by means of the double pendulum this light may be cut off periodically at intervals of, say, one-half second. To render the motion of the fluid particles visible a mixture of xylol and carbon tetrachloride in certain proportions gives a fluid which is of the same density as water so that it floats, but forms spherical drops in it like oil. The very small particles of this oil which are allowed to float along the channel past the model are

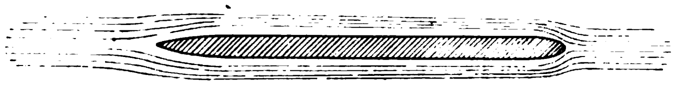

Fig. 7—Diagram drawn from photograph showing lines of flow past thin plate

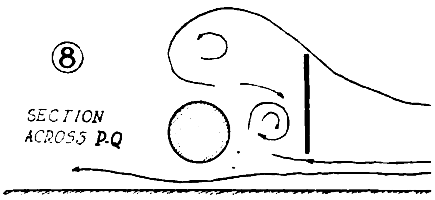
produced by means of a simple form of atomizer, whose position in and relation to the water channel is obvious from Fig. 5.

The very small globules of oil produced at the atomizer A float down the channel, and those which lie within the thin layer of fluid illuminated by the arc lamps are visible from above as a series of brilliant points of light, alternately appearing and disappearing for intervals of one-half second as the light is shut off by the double pendulum.

Under these circumstances a loaded camera placed as in the diagram vertically above the region of the model, and focussed on the illuminated plane in the fluid, will take an image of the system of stream lines and provide the speed of each point, for each brilliant point of light will appear on the photographic plate as a series of dashes along the path it traced out in its motion, each dash being proportioned in length to the distance traversed in the half seconds during which the field was illuminated. The lengths of these dashes are therefore proportional to the speed of the fluid at the midpoint of the dash. Such a photograph of a simple nature is that shown in Fig. 7, representing the flow past a thin plate.

An analysis of the flow of liquids along these lines has thrown a considerable amount of light on the conditions under which eddying originates, and on the relation between resistance and eddying. It has become apparent, for example, that for a body of given shape at a particular value of $v \times l$, violent eddying originates in the rear of the body. If the nose of the body be nicely rounded with a tapering tail the eddying or turbulent region becomes confined to a narrow region in the wake; the nar-



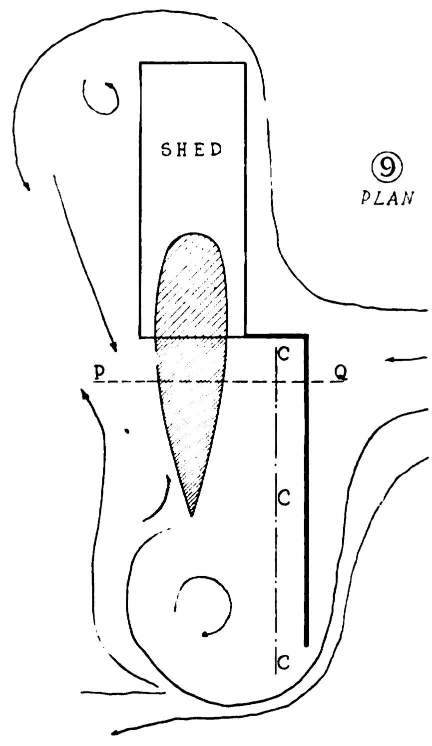


Fig. 8—Illustrating effect of air eddies on dirigible while entering hangar

Fig. 9—Arrangement of screen for hangar designed to prevent dirigible being pumped against ground

rower this wake the smaller the resistance. For example, the resistance of a wire or circular rod can be diminished to almost one-sixth of its value by fixing a fairing piece to the rear, the presence of this additional piece facilitating the smooth flow of the air. This principle is utilized in the design of aircraft to a very great extent, even to minute details. Struts, body, wires, and even nuts, are all smoothed and tapered off to reduce the parasitic resistance to a minimum.

But it is not merely in its effect on resistance that eddying is of such importance. The problem of housing airships, bringing them into and removing them from their sheds has raised many difficult problems. A gust of wind eddying over the edge of the airship shed may circulate in the region of the ship, buffet it about and dash it into the ground. In the early days of the war difficulties of this nature caused much worry and anxiety, but experimental analysis of the flow of air in the neighborhood of airship sheds and screens served to throw considerable light on the problem at issue. Smoke issuing from thin pipes, small balloons attached to strings, and, when dealing with wind channel tests on models, small pieces of cotton wool attached to the ends of silk threads were all used to show the direction of air-streaming, where and how the eddying, turbulence and circulation arose.

The annexed diagram, Figs. 8 and 9, gives a rough plan of the shed and simple screen, with the airship half out of the shed. There are in general three centers of violent turbulence. A form of whirlpool is thrown off from the vertical edge of the screen, inflicting by the back draught a heavy blow on the tail of the ship, driving it into the screen. Superposed on this, but not nearly so violent, is the eddy formed at the vertical edge P of the shed. Both these centers of disturbance have the effect of driving the tail toward the screen. But a much more insidious eddy is formed than either of these two. The top horizontal edge of the screen, acting as an eddy-forming center—an eddy with horizontal axis C C C—gives rise to a violent down draught on the top of the airship, tending to drive the tail into the ground. For practical purposes an upward force would not have serious drawbacks, as it could be counterbalanced by dragging ropes, but a downward pressure cannot be directly warded against. To counterbalance this, the lower edge of the screen is not allowed to reach the ground, but about 6 ft. of clear space is allowed to permit the wind to enter below the ship and exert an upward pressure. Fig. 8 gives an indication of the nature of the air flow resulting.

Although all the evils caused by these eddying centers cannot be avoided, by a suitable adjustment of the screen with reference to the prevailing winds, suitable fixing of heights and spacings, their effects may be considerably mitigated. The diagrams given indicate that the prevailing wind is at right angles to the direction of the screens. As the vertical edge of the screen is turned in a clockwise direction, the center of turbulence moves farther and farther off, until when the vertical edge has been turned through about 50 deg., the effect is almost inappreciable. As far as the present discussion is concerned, it is sufficient to note that by an analysis of the type of flow and the principal factors affecting it, the nature of the forces brought into play may be predicted and to a considerable extent safeguards taken.

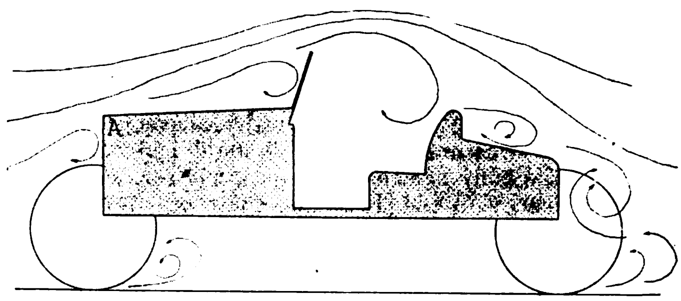

Fig. 10—Eddies produced by motion of automobile

From the general considerations outlined above and illustrated, a fairly accurate picture may be drawn of the nature of the air flow in the neighborhood of a body of almost any given shape—experiments analyzing the flow of air past the projecting portions of an automobile and the forces on the component parts measured with a view of determining whether reductions in resistance can be secured by suitable modification. Roughly, the nature of the flow is of the type shown in Fig. 10.

Several points at once become apparent. The eddying of a violent nature behind the body of the car, coupled with the eddying behind the wheels, will tend to pick up the dust in whirlpools. A more streamline overall shape would undoubtedly help to diminish this. The presence of sharp projections, as cited, likewise contribute to the parasitic resistance. Two cars fitted with different bodies and tested for resistance showed that at a speed of 30 miles per hour nearly 1 hp. could be saved by simple body considerations alone, while the mudguards, to which generally no attention is paid with a view to diminishing their parasitic resistance, are responsible for fully half the total air resistance of the complete car.

Commercial Aviation in Australia

ALREADY there are in existence in Australia three companies formed for the expressed purpose of engaging in commercial aviation. They are probably only the first swallows of the aeronautical summer that is about to burst upon us, for legally, as far as aviation is concerned, this continent is still under the shadow of the War Precautions Act.

So, as already prognosticated in these pages, civil and commercial aviation is upon us before Australia is ready for it. In the case of every one of these companies, it looks as though the money of the shareholders will have to be spent on work that should long ago have been done by the Government.

If a company proposed to start a motor service between Sydney and Manly, it does not expect to have to survey a road, build bridges or inaugurate a punt service at the Spit. Both our Governments—National and State—knew that commercial aviation was most assuredly coming. Also, they both knew that the war would end some day, and that if it ended in our favour there would be some hundreds of first-class, war-trained aviators returning to this country.

They owed it to themselves and the country to see that Australia should have the benefit of that splendid material.

However, nothing has been done.

Fortunately this is a business in which it is never too late to mend. There is nothing to prevent the Australian or the various State Governments starting a hurry-up movement in connection with aviation. In fact, they simply have to get the proverbial move on. Aviation is like every other great world movement, and will wait for no Government. It is here. If the Goverment isn't ready to meet it, so much the worse for the Government, and those whom the Government represent. It is as impossible, once peace is declared, to prevent the Australian people taking to the air as it was to prevent them taking to the surf some decade and a half ago. They'll do it, for a certainty. From *The Motor in Australia.*

Farm Tractor Design

A Mathematical Discussion of Some of the Problems That Must Be Solved, Together with Tabulated Data on Power Requirements, Soil Packing and Other Items

By Joseph Jandasek, M.E., E.E.

A GREAT deal of matter has been written about farm tractors, but most of it deals with the subject in a popular way. Such articles, while useful in their proper sphere, are of little value to a practical tractor designer. The tractor has already passed its period of invention and is now a manufacturing object; therefore, the cut and try methods by which most of the machines have been built in the past will no longer do. To turn out a good product, the design and development of a new machine must be placed in the hands of an experienced engineer who is thoroughly posted on the subject from the theoretical as well as the practical point of view. It cannot be emphasized too strongly that theory and practice must always go hand in hand and support each other, if we want to obtain the best results. Among our technical men there is a strong prejudice against the mathematical theory of machines, and many a first-class engineer, dreading the reputation of an over-technical theorist, rather adopts an inferior but more conventional method of design. This attitude, however, is bound to change gradually, to the benefit of our industries in general.

Tractors will be needed in almost every part of the world. Our tractor manufacturers have at present exceptional opportunities to secure a good foothold on foreign markets, if they only offer the right product, i.e., a product built on principles of quality and service. We must not forget that the foreign maker also is devoting his attention to the tractor. We know that he is making a very thorough investigation of the results that we have already obtained, and there is no doubt that he is going to make use of our experience and build on the basis that we have established. If we do not look out, he may eventually reach a higher plane of development than we.

To retain our supremacy in the tractor industry we have to put our research work on a more scientific basis. The world war proved unquestionably how much real scientific research work is worth to a nation. No matter how perfect a product seems to be, there is always room for improvement, and as long as the tractor is still far from a state of perfection there is much room for improvement. Most of the larger manufacturers have their experimental departments, but they are still very often conducted on the old cut-and-try principle. If the research work were carried on in the right manner and by men properly fitted for the task, it would be of great value for the concern in particular and for the whole tractor industry in general.

Before starting the design of a new machine the designer should get thoroughly acquainted with the status of the art, study carefully the existing machines and

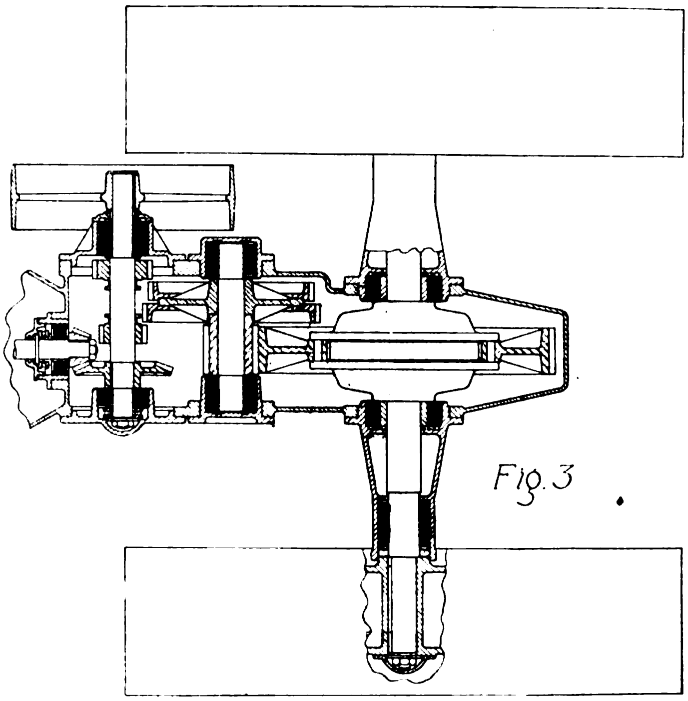

Fig. 3

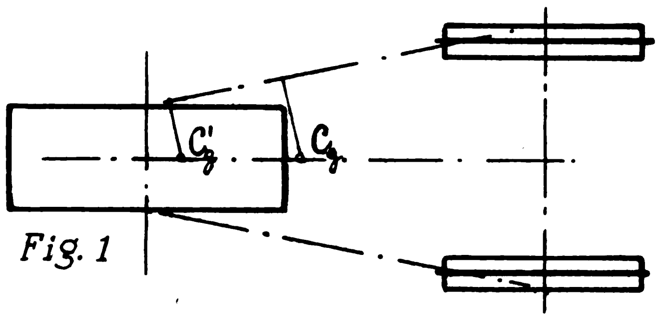

Fig. 1

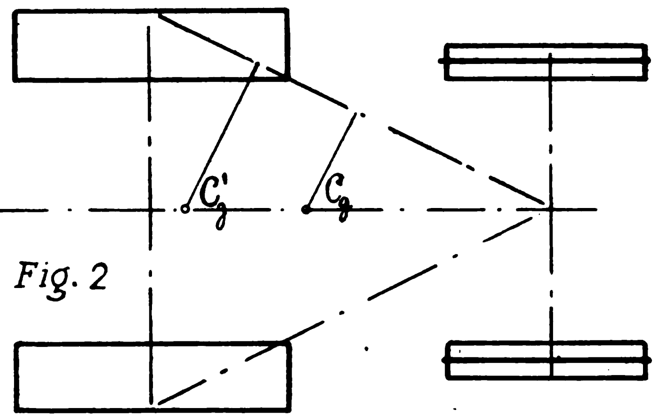

Fig. 2

Fig. 4

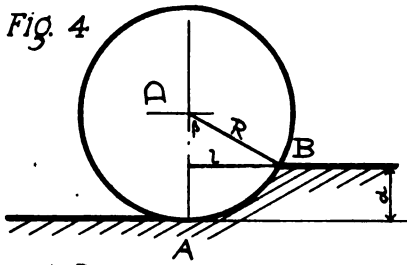

Fig. 5

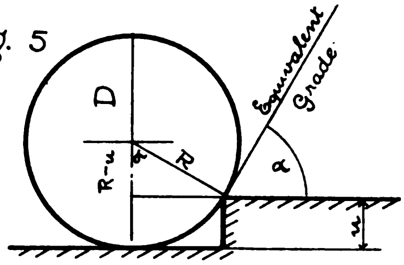

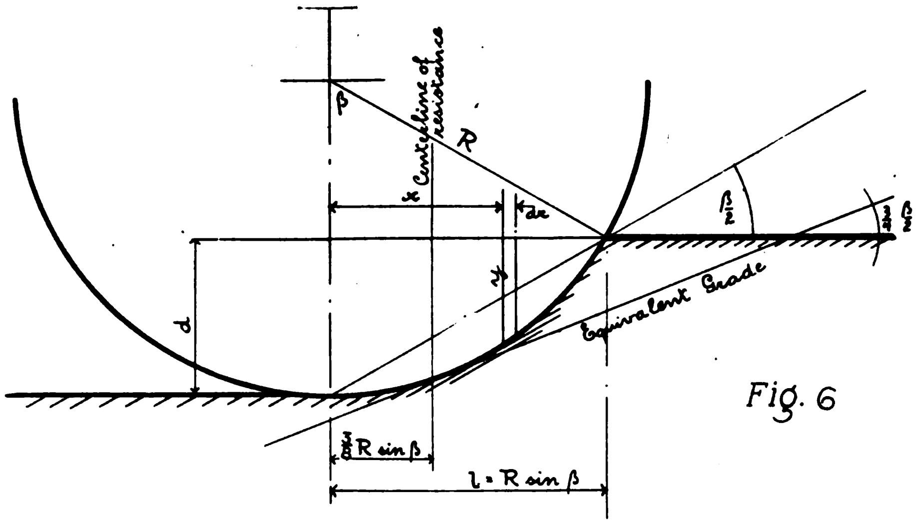

Fig. 6

familiarize himself with the latest trends in tractor design.

We may divide motor propelled farm vehicles into three distinct classes:

1. Motor plows, i.e., tractors carrying plows under them. This type of tractor is not very popular, because placing the plows under the machine makes the latter very high, heavy and clumsy, and the plows are not readily accessible for cleaning and other purposes.

2. Plain tractors, which can be used for plowing, harvesting, planting, belt work, road hauling, etc. This is the most popular and within certain size limits the most economical machine for use on the farm at present; it is also the best manufacturing proposition in the tractor field.

3. Motor cultivator and garden tractor. These machines are the youngest members of the tractor family, and, at present, in their first stage of development. However, there are great possibilities for the future along these lines.

Having decided what kind of machine to build, we must next determine its capacity or size.

In the plain tractor class the most useful machine for the average farmer is a three-plow outfit, though it seems that the two-plow tractor is destined to be the favorite and the biggest seller. Practical tests have proved that a three-plow machine is superior to a two-plow, because it can run also a small grain separator and is more economical as to fuel consumption. With a three-plow machine one man can accomplish 50 per cent more work than with a two-plow outfit of the same speed. In brief, a three-plow tractor works more economically. For large farms, of course, a four-plow tractor is still more suitable than the three-plow, and there will always be a reasonable demand for machines of the larger sizes.

The weight of the tractor should be reduced as much as practical to prevent miring in soft ground and packing of the soil. At the same time we must, however, provide for sufficient strength of parts to prevent breakage and keep the unit stresses below those of automobile and motor truck practice.

All working parts must be enclosed so as to be protected against dust and weather, yet readily accessible for repairs and adjustments. They must be constructed so as to be capable of working at full load for long periods and under all weather conditions, and require minimum attention. The lubrication should be automatic, and an effective cooling system should be provided. The material and workmanship must be first class throughout. Wherever the designer has a choice between two or more equally good constructions he should use the one which will require the least attention from the farmer.

What kind of driving members shall we select? Wheels seem to be the most logical, and the wheeled tractor will always have the widest market, because of the simplicity, reliability, endurance, small weight and low price of the wheels. Where, however, the tractor is intended for softer grounds we have to choose the crawler. A drum is not nearly as practical as wheels or as the crawler and therefore will not be considered here.

The four-wheel-drive tractor is naturally superior to a two-wheel-driven one when regarded solely from the traction point of view, yet, 90 per cent of the farmers can secure a sufficient amount of traction from a two-wheel-drive machine, and it would, therefore, be only an unnecessary outlay of money for them to buy the more

Fig. 7

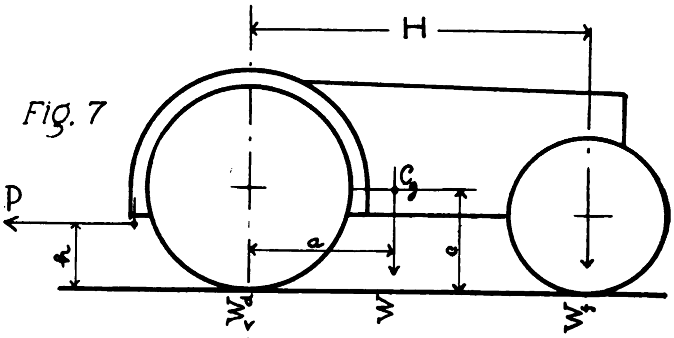

Fig. 8

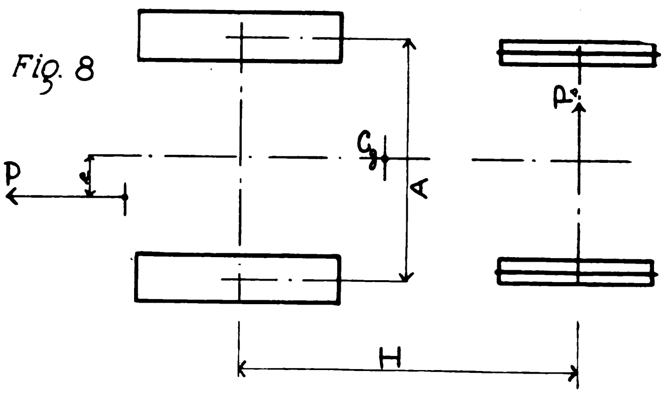

costly four-wheel-drive tractor. Of course, when the territory is very hilly the four-wheel-drive tractor or the tracklayer type can be recommended, even if the original cost be higher. The two-wheel-drive tractor should have its two driving members located at the rear. This type possesses the greatest stability and the highest weight economy. When there is only one wheel in the rear, the machine is apt to tip over when pulling heavily, especially rounding corners or on side hills, because the more this machine pulls the lower is its stability. (See Fig. 1.) On the contrary, with two wheels in the rear, the more the machine pulls the greater is its stability (see Fig. 2). The driving members should be located at the rear because with that arrangement the heavier the pull the greater the weight resting on the drivers.

The front-wheel-drive type does not have as good weight efficiency as the rear-wheel drive; still, it may be considered for machines of smaller capacity. For certain special kinds of tractor, front-wheel drive is even of advantage, as, for instance, two-wheel tractors so designed that the operator may sit on the implement; also machines intended for crossing ditches, mudholes, etc.

A single driving member in the rear is a recognized failure because of its poor stability (see Fig. 1) and is rapidly disappearing from the market.

Two front wheels for steering are unquestionably better than one, because a single front wheel located on one side introduces difficulties in steering in soft ground or on side hills. When placed in the center, the forward end of the tractor must stand also all the bumps and shocks of a worn-out country road. Therefore, three-wheel tractors are constantly loosing ground and in the future will probably be discarded entirely.

Transmission Should Be Straight Gear Drive

The transmission of a modern tractor should be a straight gear drive, all enclosed and running in a bath of oil, and a responsible tractor designer endeavoring to turn out a quality product will not decide for anything else. Not a single gear must be left exposed, no friction drive or open chain drive can be considered. Spur gears are to be used wherever the construction permits, because they are the most reliable and can stand the most abuse. Bevel gears are entirely satisfactory when correctly proportioned, though they are more sensitive than spur gears and require more attention. Worm gears cannot stand much abuse and require good and positive lubrication. How far this type of gearing will be practical for farm tractors remains to be decided. The use of the worm gear directly on a live rear axle does not seem to be very reliable, on account of the enormous tooth pressure resulting from the great gear reduction used on tractors. Consequently, the worm gears heat highly even when careful lubrication is provided. Nevertheless, some tractor makers are giving this type of gearing a trial and, for small and low powered machines, it may prove satisfactory.

Anti-Friction Bearings

As to bearings, the anti-friction types are the only ones to be considered, as they are most efficient, require little attention and, if well proportioned, run almost indefinitely without appreciable wear. The accompanying illustration (Fig. 3) represents a typical anti-friction transmission.

The longitudinal weight distribution is of paramount importance in the design of a tractor and will receive due attention in another part of this article. For the present it will suffice to point out that the more powerful the engine, the larger the gear reduction, the greater the height of drawbar and the greater the rolling resistance, the greater should be the proportion of the weight on the front wheels, in order to prevent tipping over of the machine when pulling heavily or while on steep hills. The center of gravity should be as low as possible so as to insure perfect lateral stability, while still leaving enough clearance.

Preliminary Calculations

After we have decided on the type and size of the machine to be built, the next thing is to find the necessary amount of pull and power.

The required drawbar pull is usually determined from the number of plows the tractor has to pull. It is usually considered that 700 lb. of drawbar pull is sufficient to pull one 14-in. plow in Middle West soils; but we must allow one-third more as a reserve for hard and tough places, which makes a total of 935 lbs. In other words, we need in the Midle West about 1000 lb. and in Eastern States about 1200 lb. of drawbar pull for every 14 in. bottom at plowing speed, provided that the tractor is equipped with a low speed for emergency, which low speed should be about two-thirds of the plowing speed in order to develop 50 per cent more pull. In case the plowing speed is at the same time the lowest speed, the necessary maximum drawbar pull should amount to 50 per cent more, i. e., up to 1500-1600 lb. for every plow to be guaranteed at this speed. This means the actual maximum pull and not the rated maximum pull, which should be only 80 per cent of the maximum pull. The average pull in lb. required in different soils for one 14-in. bottom, plowing 6 in. deep, is about as follows:

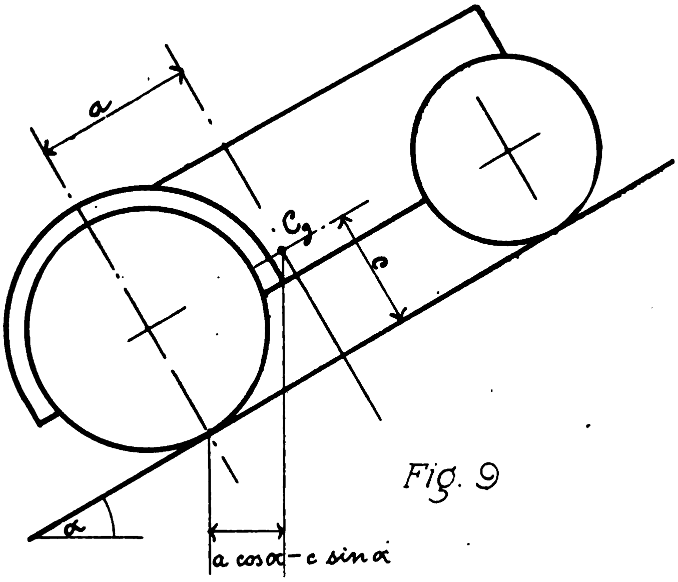

Fig. 9

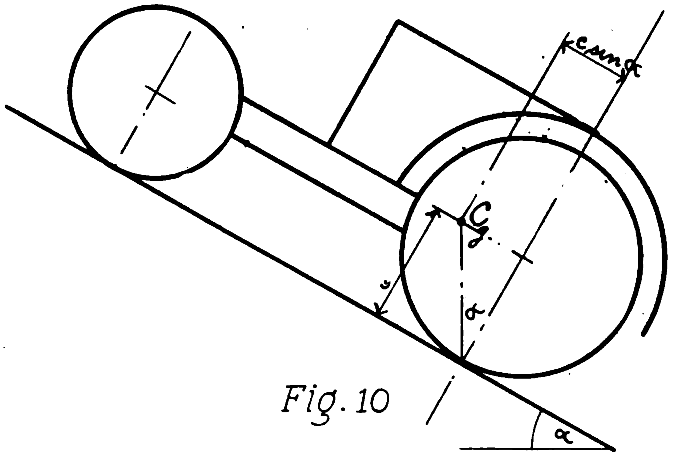

Fig. 10

Stubble	400-500 lb.	Sod	1000-1500 lb.
Clay	600-700 lb.	Gumbo	1500-1800 lb.

The drawbar pull needed for other implements runs about as given in the table below:

Binder, 6-8 ft.	800-1000 lb.
Grain drill, 7 ft.	400- 800 lb.
Disk harrow, 6-8 ft.	800- 900 lb.
Lister set	800 lb.
Double row cultivator	600 lb.
One-row cultivator	400 lb.
Corn planter	400 lb.

Weight

The total weight of a tractor should be in a definite proportion to the drawbar pull. We may say that under average soil and weather conditions the machine will pull about 80 per cent of its total weight. But since the rated maximum pull should be only 80 per cent of the actual maximum pull, the actual maximum pull at plowing speed may be equal to the total weight of the machine. The emergency pull at low speed may be up to 50 per cent greater. This maximum pull is available only for momentary use, as it would result in great slippage and loss of power when used for continuous operation. The above may be put into formulæ as follows:

$P_p = W$ lb. (on level soil for rear wheel drive) ..... (1)

$P_l = 1.5\ W$ lb. ..... (2)

where P_p = Max. pull at plowing speed.
P_l = Max. pull at low speed.
W = Total weight of tractor.

In taking the total weight of the tractor for W in our calculations we are making a slight error, as it is only the weight on the drivers at the heaviest pull that really counts. This is permissible, however, as with the rear wheel drive the weight left on the front wheels at maximum pull does not amount to much.

Rolling Resistance

The pull required to propel a vehicle on the level is equal to about 15 per cent of its weight in stubble plowing and up to about 25 per cent on soft soils. For light two-plow outfits with comparatively long and sharp spade lugs it amounts to about 20 per cent, while with track-layers it is only about 12 per cent.

t = 0.15 lb. per lb. for stubble fields ..... (3)
t = 0.25 lb. per lb. for soft or recently plowed soils. (4)
t = is the traction effort or ground resistance in lb. per lb. of total tractor weight.

To simplify matters, in the following calculation t will be assumed to be a constant, while actually it varies with the size of wheels.

For grade resistance, i. e., the amount of pull necessary to propel a vehicle up a hill of a certain grade, it seems safe to take:
g = 0.10 to 0.15 lb. per pound of weight ..... (5)
provided the tractor is designed for fairly level countries.

Speed

The proper emergency speed is about 1¾ to 2½ m.p.h. The plowing speed can range from 2½ up to 3½ m.p.h. The tendency to-day is naturally toward higher speed in plowing, which is proving successful in districts with light soils, but is impracticable in stony fields. The proposed standard plowing speed of 2 1-3 m.p.h. is altogether too low for a modern machine. The actual speed is from 5 to 15 per cent lower on account of the constant slippage of the driving members. The high speed or road speed can be taken at from 3½ to 8 m.p.h. according to the weight, size and spring mounting of the tractor. There is no demand for more than three forward speeds; however, less than three speeds results in cutting down the efficiency of the tractor.

Horsepower

After we have decided on the speed and drawbar pull of our machine we can calculate the drawbar horsepower. Then, estimating the ground and grade resistance and transmission efficiency, we obtain the brake horsepower of the tractor. The formulæ for these calculations are:

$$\text{DHP} = \frac{P_p}{375} S_p \text{ drawbar horsepower} \quad (6)$$

$$\text{BHP} = \frac{P_p + (t+g)\,W}{375\ E_t} Sp \text{ brake horsepowers} \quad (7)$$

where E_t = Mechanical efficiency of transmission.
S_p = plowing speed in m.p.h.
$(t+g)$ = ground and grade resistance in lb. per 1 lb. of weight.

For a quick calculation of the available drawbar horsepower we can develop an easy formula by substituting in equation (7) as follows:

$W = P_p$ for light and high-powered tractors
$t + g = 0.25$
$E_t = 0.84$

$$\text{BHP} = \frac{P_p\ S_p}{375}\left(\frac{1+0.25}{0.84}\right) \text{ (3 gearsets)}$$

$$\text{BHP} = 1.5 \text{ DHP} \quad (8)$$

$$\text{DHP} = \frac{2}{3} \text{ BHP (for light, high-grade machine)} \quad (9)$$

We can still further simplify the calculation of the pull P at 2½ m.p.h. since one horsepower is equal to 150 lb. pull at this speed; hence,

$$\text{DHP} = \frac{P}{150} = \frac{2}{3} \text{ BHP},$$

and, finally,

$$P = 100 \text{ BHP at } 2\tfrac{1}{2} \text{ m.p.h.} \quad (10)$$

That is, each brake horsepower is developing about 100 lb. of pull at 2½ m.p.h., on modern, light high-grade tractors.

Piston Speed

Tractor engines work about 80 per cent of the time at full load. Therefore, the unit stresses and pressures must be kept lower and the piston speed mustn't be as high as on automobiles or motor trucks, in order to prevent too rapid wear and other troubles. Also, the cooling system must be very effective. A normal piston speed of 900 ft.p.m. has proved very practical and is widely used, and it is not advisable to go much above this, especially not with the present four-cylinder engines. The formulæ for determining piston speed or r.p.m. are:

$$N = 6\frac{V_p}{L} \text{ r.p.m.} \quad (11)$$

$$V_p = \frac{LN}{6} \text{ ft.p.m.} \quad (12)$$

and that the ratio between stroke and bore is:

$$L = 1.25 \text{ up to } 1.4 \text{ B} \quad (13)$$

in which N = r.p.m.
V_p = piston speed in ft.p.m.
L = length of stroke in in.

In the table below are indicated the r.p.m. corresponding to a piston speed of 900 ft.p.m. for different lengths of stroke:

Stroke, in.	Speed, r.p.m.	Stroke, in.	Speed, r.p.m.	Stroke, in.	Speed, r.p.m.
4	1350	5¼	1029	6½	831
4¼	1271	5½	982	6¾	800
4½	1200	5¾	940	7	771
4¾	1137	6	900	7¼	745
5	1080	6¼	864	7½	720

When determining the necessary BHP of a tractor we have to take the belt work into consideration:

$$\text{Belt HP} = E_b \text{ BHP} \quad \ldots\ldots (14)$$

Where E_b is the efficiency of the gearset between the pulley and engine, if any.

The most important belt work is threshing, which at the same time is very hard on the engine. The horsepowers needed for threshing vary a good deal with the quality of the grain to be threshed. There is no general formula, but we can use the following table for determining the belt horsepowers required for different sizes of grain separators:

Width of cylinder	Required belt horsepower
18 in.	22 hp.
20 in.	24 hp.
24 in.	30 hp.
26 in.	34 hp.
28 in.	36 hp.
32 in.	45 hp.
36 in.	60 hp.

From the above table it will be seen that a tractor equipped with an engine under 30 hp. has only a limited belt work capacity and can be used only on small size farms or where there is another, larger source of power available for threshing.

Other machines, such as corn shellers, hay presses, feed grinders, ensilage cutters, etc., require usually from 8 up to 30 belt horsepower.

Assuming the standard belt speed of 2600 ft.p.m., we obtain for the diameter of pulleys

$$d = \frac{10{,}000}{n_p} \text{ in. (appr.)} \quad \ldots\ldots (15)$$

where n_p is the r.p.m. of the pulley.

Widths of pulleys may be made as follows:

6½ in. for machines of 16-20 BHP
7½ in. for machines of 20-30 BHP
8½ in. for machines of 30-40 BHP
9½ in. for machines of 40-60 BHP

For calculating the horsepower of belts and pulleys we can use the following formulæ:

$$\text{Belt HP} = \frac{d\ w\ n_p}{2860} \text{ for a pulley with a single belt}$$

$$\text{Belt HP} = \frac{d\ w\ n_p}{1720} \text{ for a pulley with double belt}$$

$$\text{Belt HP} = \frac{w\ s}{900} \text{ for single belt}$$

$$\text{Belt HP} = \frac{w\ s}{630} \text{ for double belt}$$

where w is the width of the belt in in. and s the belt speed in feet per minute.

Engine Dimensions

Assuming that the mean effective brake pressure with modern four-cycle gasoline engines equals 80 lb. per sq. in., we obtain for the calculation of the brake horsepower

$$\text{BHP} = \frac{B^2\ L\ N}{12600}\ 4 \quad \ldots\ldots (20)$$

$$\text{BHP} = \frac{N\ C}{\pi\ 12600}\ 4 \quad \ldots\ldots (21)$$

$$\text{BHP} = \frac{.7854\ B^2\ p\ V_p}{33000} \quad \ldots\ldots (22)$$

in which B is the cylinder bore in in.; p, the brake mean effective pressure in lb. per sq. in., and C the piston displacement in cu. in.

If we want to be more conservative and take the brake mean effective pressure at 72 lb., we have the well-known formula:

$$\text{BHP} = \frac{B^2\ L\ N}{14000}\ 4 \quad \ldots\ldots (23)$$

for 4-cylinder 4-cycle gasoline engines.

For determining the torque we can use

$$T = \frac{B^2\ L\ p}{4} \text{ in.-lb.} \quad \ldots\ldots (24)$$

or

$$T = \frac{C\ p}{4\pi} \text{ in lb.} \quad \ldots\ldots (25)$$

Substituting 900 ft.p.m. for V_p and 80 lb. for p in equation (22) we obtain for the brake horsepower

$$\text{BHP} = 1.71\ B^2 \quad \ldots\ldots (26)$$

and for the diameter of the bore we get

$$B = 0.765\sqrt{\text{BHP}} \quad \ldots\ldots (27)$$

In the following table are given brake horsepowers of 4-cylinder engines of different bores when the mean effective brake pressure equals 80 lb. per sq. in. and the piston speed 900 ft.p.m.

B in in.	BHP	B in in.	BHP
3½	21.0	4½	34.6
3¾	24.0	4¾	38.6
4	27.3	5	42.6
4½	31.0	5¼	47.0

If we assume that when kerosene is used as fuel there is a loss of 15 per cent in the horsepower of the engine, the above formulæ (26) and (27) become

$$\text{BHP} = 1.45\ B^2 \quad \ldots\ldots (28)$$

$$B = 0.83\sqrt{\text{BHP}} \quad \ldots\ldots (29)$$

for 4-cylinder 4-cycle kerosene engines.

As to the kerosene burning problem, it is the writer's opinion that any attempt to solve it by designing kerosene carbureters, manifolds, etc., is absolutely hopeless, because there are too many undeterminable factors regulating the vaporization of the fuel and the combustion of the mixture, viz., the quality of the kerosene used, temperature, heat conductivity, horsepower capacity, r.p.m., volume and velocity of mixture, shape of cylinder head and manifold, time, compression, etc. The only simple solution is to atomize the fuel positively by injecting it into the cylinder at the moment of combustion, so that there can be no recondensation. In this way all the spark plug, magneto and carbureter trouble would be eliminated. From my personal observation and experience with motors of the injection type, I can say that the Diesel engine is the most perfect and most reliable. However, being too complicated and too heavy, it does not seem suitable—at least, not in its present form—for propelling vehicles. The Brons motor (very similar to the Hvid) is reliable and very simple, though not as clean working and not as economical as the Diesel. As an engine for vehicle propulsion the Brons motor has, however, also a drawback. There is a slight irregularity in the timing of the explosion and it is impossible to regulate same. Direct liquid injection would be ideal provided that we could insure sufficiently fine spraying of the fuel. With all injection type engines the main problem is to regulate the minute amount of fuel necessary for each explosion.

Gear Ratio

The gear ratio of a tractor is

$$G = \frac{N}{n} \quad \ldots\ldots (30)$$

where n is the r.p m. of the driving wheels, which can be determined as follows:

Peripheral speed of wheel $= \dfrac{\pi\ D\ n \times 60}{12 \times 5280}$ miles p. h.,

and this is equal to the tractor speed S; hence

$$S = \frac{D\ n}{336} \text{ miles p. h.} \quad \ldots\ldots (31)$$

$$n = \frac{S}{D} 336 \text{ r.p.m.} \quad \ldots\ldots (32)$$

where D is the diameter of the driving wheels in in.

Substituting in equation (30) for n the value found in equation (32) and for N the value of equation (11) we obtain:

$$G = 16.1 \frac{D}{SL} \quad \ldots\ldots (33)$$

This is the gear ratio required for a tractor if the piston speed is 900 ft.p.m. For a tractor speed of 2½ m.p.h. (a good speed for hard plowing) this simplifies to

$$G = 6.44 \frac{D}{L} \quad \ldots\ldots (34)$$

Sometimes the r.p.m. of an engine are determined without taking piston speed into consideration. Usually, 900 r.p.m. is the speed selected, and in that case we have

$$G = 2.68 \frac{D}{S} \quad \ldots\ldots (35)$$

Further, for a tractor speed of 2½ m.p.h. and 900 r.p.m. of the engine we get the following very useful formula for quickly calculating of gear ratio:

$$G = 1.07\ D \quad \ldots\ldots (36)$$

Drawbar Pull and Horsepower

When the engine dimensions are given we can determine the available drawbar pull in the following way:

Torque on rear axle $= E_t GT$ in.-lb.

The corresponding tangential force is $2\,\dfrac{GTE_t}{D}$ lb., and this is equal to the drawbar pull P plus the rolling resistance $(t + g)\ W$, hence,

$$P + (t + g) W = 2\ \frac{GTE_t}{D} \text{ lb.}$$

$$P = \frac{2\ E_t\ GT}{D} - (t + g)\ W \text{ lb.} \quad \ldots\ldots (37)$$

Substituting for T from equation (25) we obtain

$$P = \frac{2\ E_t\ G}{D} \times \frac{Cp}{4\pi} - (t + g)\ W \text{ lb.} \quad \ldots\ldots (38)$$

The drawbar horsepower DHP can be calculated from the dimensions of the engine as follows:

$$\text{DHP} = \text{BHP}\ E_t - (t + g) W\ \frac{S}{375} \quad \ldots\ldots (39)$$

Equations (38) and the following equation are being used by the writer for comparing tractors of different makes:

$$\text{DHP} = \frac{N\ C\ 4}{\pi\ 12600} E_t - (t - g)\ W\ \frac{S}{375} \quad \ldots\ldots (40)$$

Wheel Sizes

When a wheel is rolling over soft ground it is supported only on a part of its periphery (*AB*, Fig. 4) ahead of the axle, because the soil is not elastic. The projected bearing surface equals lF, and since it is known from geometry that $l = \sqrt{(D - d)\ d}$ we obtain

$$\text{Area} = F\sqrt{(D - d)\ d} = F\sqrt{(D\ d - d^2)}$$

where d is the depth the wheel may be allowed to sink into the ground and F the face width of the rear wheels, both in inches.

Because d is very small in proportion to D we can safely omit the member d^2, which gives

$$\text{Area} = F\sqrt{D\ d} \text{ sq. in.}$$

For $d = 1$ in. we get:

$$\text{Area} = F\sqrt{D}$$

Allowing a mean pressure i in lb. per sq. in. of ground contact and making $d = 1$ in. we get the weight which can be safely supported by two rear wheels, or, in other words, practically the total weight of the tractor, as at heavy pulls almost all the weight is carried on the two rear wheels.

$$W = 2\ i\ F\sqrt{D} \text{ lb.} \quad \ldots\ldots (41)$$

Assuming i = 17 lb. per sq. in. we obtain

$$W = 34\ F\sqrt{D} \text{ lb.} \quad \ldots\ldots (42)$$

for the 2 rear wheels of width of face F in. each and

$$F = \frac{W}{34\sqrt{D}} \text{ in.} \quad \ldots\ldots (43)$$

When the tractor is standing still and not pulling, the weight resting on the front wheels is at its maximum and amounts to about $\dfrac{W}{3}$; therefore, for the 2 front wheels equations (41), (42) and (43) become

$$W_f = 2\ i\ f\sqrt{D_f} \quad \ldots\ldots (44)$$

where $W_f = \dfrac{W}{3}$ (approx.)

$$W = 100\ f\sqrt{D_f} \text{ lb.} \quad \ldots\ldots (45)$$

$$f = \frac{W}{100\ \sqrt{D_f}} \quad \ldots\ldots (46)$$

From the following table we can readily determine the supporting area in sq. in. of a wheel as well as the mean pressure i in lb. per 1000 lb. supported by a wheel of definite diameter and width, assuming the depth d that the wheel sinks into the soil to be 1 inch:

SUPPORTING AREA AND SOIL PRESSURE OF TRACTOR WHEELS

Supporting area $= F\ \sqrt{D}$ sq. in. mean soil pressure $= \dfrac{1000}{F\sqrt{D}}$ lb.

Wheel dia. in in.		Face of Wheel in inches 3	4	5	6	8	9	10	12	14
28	area....	15.9	21 2	26.4	31.8	42.3	47.6	52.9	...	...
	pressure	62.9	47.2	37.9	31.4	23.6	21	18.9	...	...

We may use this table also for comparing mean pressures under the wheels of two different tractors; the greater the pressure under the wheels the more the soil will be packed.

Example: What is the mean pressure of ground contact with the following machines:

A—Weight 5000 lb., 2 rear wheels 60 x 10 in.
B—Weight 3500 lb., 2 rear wheels 48 x 12 in.
C—Weight 2800 lb., 2 rear wheels 42 x 12 in.

Estimating that when the machine is pulling, about 80 per cent of the total weight is carried on the rear wheels, we obtain:

Mean pressure i for A = 25.8 lb.; for B, 17.4 lb.; for C, 14.4 lb.

From the standpoint of soil packing the area grows directly with the width of face and only with the square

root of the wheel diameter. Wheels of large diameter have more area of contact, are more efficient and give more traction. Their main advantage, however, is that they bridge over obstructions better.

In Fig. 5 is shown a wheel in a hole u in. deep. In order to pull out, the engine must exert as much power as when pulling the weight carried on that particular wheel up a certain grade g. This grade can be determined as follows:

$$R - u = R \cos x$$

from which

$$R = \frac{u}{1 - \cos x} \quad (47)$$

$$\cos x = \frac{R - u}{R}$$

where x is the angle of equivalent grade $g = tgx$.

Provided the tractor is equipped with a power plant calculated to develop at plowing speed on the level a net drawbar pull equal to the weight of the machine, the tractor can climb up a grade of 45 deg. with small load. In this case equation (47) becomes

$$D = 6.83u \quad (48)$$

The table below gives the minimum diameters of wheels with which tractors having a drawbar pull equal to their weight could pull out of holes in the ground of a depth u provided both rear wheels were climbing at the same time, with all weight resting on the rear wheels at that moment:

D, in.	u, in.	D, in.	u, in.
20	2.9	42	6.1
25	3.7	48	7
30	4.4	54	7.9
36	5.2	60	8.8

In case the machine is equipped with an emergency gear reduction giving 50 per cent more pull than the plowing gear, the operator can shift into low and in this way make the tractor climb out of a hole corresponding to a 100 per cent grade and still be able to develop 50 per cent of its maximum drawbar pull P_p.

Thus it will be readily seen how important it is to select driving wheels of the proper diameter, and it is not advisable to go under 48 in., as otherwise the machine might not climb up even a shallow ditch.

As regards the size of front wheels, they must not be too small in proportion to the rear wheels.

Influence of Wheel Dimensions on Ground Resistance

It is no doubt of value to the tractor designer to have an idea regarding the relation between the wheel dimensions (diameter and face of wheel) and the rolling resistance, and, therefore, the following mathematical derivations were made.

Let us assume that there is no cohesion, no mud and no dust on the surface; that the pressure of the soil against the tire increases in direct proportion with the depth of depression; that the pressure is nil at the surface and q lb. when the soil is depressed 1 in. deep; we than have (Fig. 6) and

$$dW = qydxF$$

$$W = qF\int_0^l ydx$$

where the integral is equal to the area of the half segment which was displaced by the wheel. The value of q is in effect the carrying capacity coefficient of soil in lb. per cu. in. The area of the half segment (see Fig. 6) is $\frac{1}{2}R^2S - \frac{1}{4}R^2 \sin 2S$, where S is given in radians. The angle S is comparatively small, hence we can substitute for it $\sin 2S = 2S - \frac{(2S)^3}{6}$, and we then get

$$W_1 = \frac{1}{12} qFD^2S^3 \quad (49)$$

in which W_1 is the weight on that particular wheel only.

When q is determined by experiment for a certain soil the value of S can be determined for any size of wheel, for

$$S = \left[\frac{12W_1}{qFD^2}\right]^{1/3} (S \text{ in radians}) \quad (50)$$

After the angle S is determined we can calculate the depth of sinking—

$$d = R(1 - \cos S);$$

the maximum pressure under the tire

$$\text{i max.} = qd$$

and the area of contact $= FR \sin S$.

Substituting in Fig. 6 a parabolic segment for the circular one we can say that the center of soil resistance is $\frac{3}{8}TR \sin S$ ahead of the axle. Consequently,

$$tW_1 \times R = W_1 \tfrac{3}{8} R \sin S$$

hence

$$t = \tfrac{3}{8} S \quad (51)$$

or

$$t = \tfrac{3}{4}\left(\frac{S}{2}\right),$$

in which $S/2$ is the slope of the chord.

Finally we get

$$t = \tfrac{3}{8}\left[\frac{12W_1}{qFD^2}\right]^{1/3} \text{ lb.} \quad (52)$$

The above equation does not take into account the action of the lugs, which, of course, increases the ground resistance considerably.

We thus arrive at the conclusion that a wider face of wheel gives less ground resistance. This conclusion, however, does not hold when the soil is muddy, sloppy and sticky on the surface but firm underneath; when deep mud is adhering to the wheels; when the soil surface is covered with deep, loose dust. The rolling resistance decreases more rapidly with increasing diameter than with increasing face of wheel.

Lug Dimensions

When determining the face of the driving wheels we must take due account of the necessary face dimensions of lugs or spurs. The action of lugs on the ground is similar to that of a pinion and rack. We may assume that only one lug is in mesh at a time, because setting the lugs too close would prevent self-cleaning in the softer soils. The pressure against the face of the lugs at a definite drawbar pull (for 2 driving wheels) can be calculated by means of the equation

$$P = 2F_l \times m \times j \quad (53)$$

where P is the drawbar pull for the two driving wheels; F_l, the length of the lug in in.; m, the depth of the lug and j the mean pressure against the face of the lug. Transposed this gives:

$$j = \frac{P}{2F_l m} \text{ lb. per sq. in.} \quad (54),$$

This pressure should not exceed 60 lb. per sq. in., as otherwise an enormous slippage and a large proportional loss of power must be expected. At the same time, however, the depth m of the lugs is limited, because the efficiency of the driving wheels is greatly lessened when m is too great. For wheels of 48-in. diameter it would not exceed 3 in.

Example: What is the pressure against the face of the lugs when $P = 3000$ lb. and $F_l = 12$ in.

Solution:

$$j = \frac{3000}{2 \times 12 \times 3} = 42 \text{ lb.}$$

The amount of traction obtainable depends upon the weight carried on the driving wheels, the size, shape, sharpness and number of lugs, the diameter and width of the driving wheels, the weather conditions and the cohesion of the soil.

Generally speaking, the greater the required traction the more weight there must be on the drivers in order to force the lugs into the ground. When the pull becomes excessive in proportion to the weight, the driving wheels start to slip considerably, the efficiency of the machine becomes very low and there is danger that the machine will stall.

When a wheel equipped with lugs rolls over the ground, the lugs being driven into the soil, the maximum resistance against the face of the lugs depends on the shearing resistance of the soil. The force of cohesion holds the particles of earth together so they resist separation. This cohesion force varies with the quality of soil, being greater in clay and smaller in ordinary soil. When the ground is plowed or otherwise cultivated its cohesion is entirely destroyed and can be regained only after a certain time and when the ground has been wetted.

Resistance

The resistance also depends on the friction of the earth. The cohesive force of the soil should be considered as active only when the ground has not been cultivated within a certain length of time, whereas the force of friction exists always. The friction between the steel tire of a drive wheel and the ground would not amount to much if the wheel were not equipped with lugs. But when the drive wheel is provided with lugs we have to consider friction of earth on earth and not friction of the wheel tire on earth. According to Rankine the coefficients of friction and angles of repose are:

Kind of Soil	Angle of Repose	Friction Coefficient
Earth on earth	14-45 deg.	0.25-1.00
Earth on earth, dry sand, clay and mixed earth	21-37 deg.	0.38-0.75
Earth on earth, damp clay	45 deg.	1.00
Earth on earth, wet clay	17 deg.	0.31
Earth on earth, shingle and gravel	39-48 deg.	0.81

From the above we may derive the following approximate values:

For vegetable soils, angle of repose, 40-41 deg., and coefficient of friction 0.83-0.87; for clay soils, angle of repose, 42-44 deg., coefficient of friction 0.90-0.97, the average being about 0.9.

The combined friction and shearing resistance might result in obtaining a greater traction or pull than the weight of the tractor. But in order to keep on the safe side the maximum drawbar pull according to the foregoing computations ought to be $P = 0.9W$ at the plowing speed.

Road Work

There are not many data available which would indicate how much drawbar pull can be safely expected from a tractor of a certain weight on different kinds of roads and under various conditions. We may say, however, that about two-thirds of the total weight can be obtained on country road if the tractor is equipped with proper lugs. This naturally varies with the weather, road conditions etc.

$$P_r = \tfrac{2}{3}W \text{ lb.} \quad (55)$$

where P_r is the available drawbar pull on the road.

The tractive effort or ground resistance of country roads varies from 7 per cent to 12 per cent, the average being 10 per cent. Allowing another 10 per cent as a reserve for grades, we can estimate the available drawbar pull of any given tractor on the road.

$$P_r = (t + g)W_h \quad (56)$$

Taking the ground resistance at 0.10 and the grade resistance at 0.10, we have for the necessary tractive effort to pull the total load W_h on the road:

$$P_r = 0.20W_h \quad (57)$$

or

$$W_h = 5P_r \quad (58)$$

and, as we estimated the maximum of pull to be two thirds of the total weight of the tractor, by substituting for P_r its value in equation (55) we obtain:

$$W_h = 5 \times \tfrac{2}{3}W_t$$

$$W_h = 3.33W_t \quad (59)$$

In other words, on country roads with grades up to 10 per cent the tractor is capable of hauling 3.33 times its own weight.

Longitudinal Weight Distribution

As already mentioned, the greater part of the traction or grip is obtained by friction of the soil particles. Hence we may say that the traction depends on the amount of pressure developed by the driving wheels, or, in other words, on the amount of weight carried on the driving wheels. To obtain the maximum amount of traction the designer will naturally endeavor to have as much weight on the drivers as possible, leaving on the steering wheels only enough weight to secure proper steering. In Figs. 7 and 8, A represents the tread; H, the wheelbase; C_g, the center of gravity; a, the distance of C_g from the rear axle in in.; c, the height of C_g from the ground in in.; e, the eccentricity of the drawbar in in.; h, the height of the drawbar in in.; W_d, the weight on the drivers at rest, and W_f, the weight on the steering wheels at rest.

The total weight W of the machine is supported by the front and rear wheels, and the value of W_f and W_d while standing still on the level depend on the distances a and H and can be determined by the following equation:

$$W_f H = Wa \quad (60)$$

$$W_d H = W(H - a) \quad (61)$$

Vice versa, we can calculate the necessary distance of C_g so that there will be a weight W_f on the front wheels:

$$a = \frac{W_f}{W} H \quad (62)$$

When plowing, it is usually not possible to hook the load exactly in the center between the rear wheels, because of differences in treads and in the width being plowed. Consequently, the center line of draft and that of the power do not coincide. This results in a moment Pe (see Fig. 8) tending to swing the tractor to one side. This moment Pe must be counteracted by a resistance P_s of the front wheels, which resistance depends on the weight carried on the front wheels. This counteracting moment must be at least equal to P_e, i.e.,

$$Pe = P_s H$$

Assuming that in order to obtain this resistance P_s an equal amount of weight on the front wheels is needed ($P_s = W_s$), we get,

$$Pe = W_s H \quad (63)$$

Further, from equation (62)

$$a_s = \frac{W_s}{W} H \quad (64)$$

or by substituting from equation (63) we have,

$$a_s = \frac{P}{W} e \text{ in.} \quad (65)$$

This value a_s represents the distance the center of gravity C_g must be ahead of the rear axle in order to

balance the effect of eccentricity e of the drawbar pull P alone.

Besides causing side draft, the drawbar pull has a tendency to tip the tractor over, on account of the moment Ph. From Fig. 7 we get,

$$Ph = W_pH, \qquad (66)$$

and, further, from equation (62),

$$a_p = \frac{Ph}{W} \text{ in.}, \qquad (67)$$

where a_p is the distance of C_g necessary to balance the moment Ph alone, representing the influence of the height of drawbar pull.

When the tractor is ascending a grade of angle x, the horizontal distance of C_g from the rear support is smaller than when it is on the level. This is illustrated in Fig. 9. The horizontal distance in the inclined position is $a \cos x - c \sin x$, while on the level it was equal to a. This diminution is equal to $a_g = a - (a \cos x + c \sin x)$. But since the angle x is small we may write $a_g = c \sin x$ or

$$a_g = cg \qquad (68)$$

In Fig. 6 it is shown that if a wheel is rolling over soft ground it has to overcome a resistance equivalent to that of a three-fourths slope of chord $= \frac{3}{4}(S/2)$ and is not supported exactly under the rear axle but $\frac{3}{8}R \sin S$ ahead of it. According to Fig. 6 this decrease in distance C_g to the rear wheel support amounts to

$$\tfrac{3}{8}R \sin S = Rt \ (S \text{ small})$$

and this also must be counterbalanced by placing C_g ahead by

$$a_t = Rt \qquad (69)$$

In order to be safe that the tractor will not tip over when the drawbar pull is applied at a certain height h above the ground, the tractor ascending a certain grade and overcoming the ground resistance t, but still will have weight enough on the front wheels to ensure proper steering when there is a certain side draft e, we must advance the center of gravity C_g such a distance as to completely counterbalance all of the above mentioned moments:

$$a = a_s + a_p + a_g + a_t$$

$$a = \frac{P}{W}e + \frac{P}{W}h + cg + Rt \qquad (70)$$

Equation (70) shows that:

1. The emergency or low speed must not be too low nor the drawbar pull P_l too high, otherwise the machine is apt to tip over and endanger the life of the operator.

2. The height of drawbar must be adjustable so the load can be hitched very low when the pull is very heavy. Otherwise the machine would either tip over or have too much weight on the front wheels when doing lighter work.

3. The center of gravity must be low to insure good weight economy on the level as well as on grades (height c small).

4. The percentage of weight carried on the front wheels, as sometimes given in catalogs, does not at all give sufficient guarantee that the machine will not tip over; the only safeguard is a definite minimum distance a between the center of gravity and the rear axle.

5. This distance a, or the location of the center of gravity, does not at all depend on the wheelbase. The longer the wheelbase the more weight there may be on the rear wheels (a being constant) and the better the weight economy.

When we are designing a new tractor we do not know the height c of C_g correctly and have to estimate same. For a preliminary calculation we can put it about equal to R; then equation (70) becomes:

$$a = \frac{P}{W}(e + h) + R(t + g) \text{ in.} \qquad (71)$$

Example: What is the minimum value of a for the following two tractors:

A has max. $P = 1.5W$
B has max. $P = W$

Other conditions are the same for both tractors, namely, $C = 6$ in., $h = 15$ in., $R = 24$ in., $t + g = 0.25$.

Solution:

A: $a = 1.5 \times 21 + 0.25 \times 24 = 37.5$ in.
B: $a = 1 \times 21 + 0.25 \times 24 = 27$ in.

The same machine which is perfectly safe with a definite pull-to-weight ratio (corresponding to a certain gear ratio) may become unstable and dangerous if the pull-to-weight ratio is increased (gear ratio too low).

What is the relative importance of the different influences on the location of the center of gravity in the case of tractor B of the above example?

Side draft a_s	= 6 in.	= 21.3%
Drawbar height a_p	= 15 in.	= 53.2%
Ground resistance a_t	= 3.6 in.	= 12.75%
Grade resistance a_g	= 3.6 in.	= 12.75%
		100%

If we consider only the influence of drawbar height, without paying attention to the other factors, as is the usual practice, the minimum safe value of a for tractor B of the above example would be 15 in., but this is only 53.2 per cent of what it should be. Thus we can see that we would make a very considerable error if we took only the drawbar height into account, instead of the sum of all the factors influencing the value of a.

Let us now discuss briefly the weight distribution in a front wheel driven tractor. It is characteristic of the front wheel drive that the more the machine pulls the less the weight resting on the front driving members. Inasmuch as most of the total weight is concentrated on the drivers (in front in this case) the machine is safe even at the heaviest pulls; but when the tractor is descending a steep hill and not pulling there is a tendency to tip over to the front. Therefore, the weight must be properly distributed with view to this condition. Consequently, for front drive (see Fig. 10)

$$a = cg \text{ in.}, \qquad (72)$$

in which a is the distance of C_g behind the front axle and g the steepest gradient which can be descended with safety.

For instance, let $c = 24$ in. and $g = 0.50$ (50% grade). Then $a = 12$ in.

When we have determined the center of gravity we can estimate the wheelbase approximately—

$$H = 2\tfrac{1}{2} \text{ to } 3a \qquad (73)$$

The tread A should be equal to about $2\frac{1}{4}c$ to insure the necessary lateral stability

$$A = 2\tfrac{1}{4}c \qquad (74)$$

(To be continued)

THE influence of turbulence on the explosibility of gas mixtures and on the working of gas engines was, though not overlooked, not sufficiently heeded until recent years. Experimenting on behalf of the British Association Committee on Gaseous Explosions (Dundee, 1912), Dr. Dugald Clerk observed that the rate of explosion rise increased with the number of rotations and decreased when the turbulence was damped down. An engine working normally with ignition at the end of the first compression stroke attained maximum gas pressure in 0.037 second; when ignition was effected at the end of the third compression stroke, i.e., after turbulence had subsided, maximum pressure was not attained in less than 0.092 second. Agitating the gas mixture contained in a closed cylinder by means of a fan, the late Professor Bertram Hopkinson found that with the fan at rest and at 2000 r.p.m. or 4500 r.p.m. maximum pressure was reached in 0.13 second, 0.03 second and 0.02 second.

Belgian Industry Has Big Task In Its "Comeback" Effort

Troubles of the Germans in Keeping Their Army Motor Equipment Running in Latter Days of War Show How Country Was Stripped—Labor Problems

By W. F. Bradley

IN his two previous articles Mr. Bradley, special European correspondent of AUTOMOTIVE INDUSTRIES, told in detail of the destruction of the automotive industry in Belgium by the German army, aided by civilians. In this article he tells something of the incidental motor troubles of the invading army and of the failure of the much talked of substitutes. He also tells briefly the problems that confront the Belgian manufacturers in resuming production. As in the previous articles, the pictures taken especially for AUTOMOTIVE INDUSTRIES at the Belgian factories comprise a vital part of this story.

In this series Mr. Bradley, who went to Belgium especially for AUTOMOTIVE INDUSTRIES, draws a convincing indictment that the Germans combined war and business. There can be little doubt that much of the destruction of the Belgian plants was due to a desire to remove an after the war business competitor. This is best shown by the continued removal and destruction of machinery after the signing of the armistice was known. If you have not read the previous articles, you should get them.

—EDITOR.

WHEN the German forces first entered Belgium they made very extensive use of automobiles. Naturally, one of their first acts was to prevent any civilian traveling by automobile. This automatically shut down the factories. Many other industries, however, continued to work for a considerable time to supply civilian needs.

Large numbers of Belgian automobile owners fled in 1914, using their cars as the best means of getting away. For a number of weeks, 2000 to 3000 Belgian automobiles were parked in the public squares of the Port of Havre. Contrary to expectations, however, the Germans did not seize many private automobiles in Belgium. Where stocks existed in the factories, they took them, but the military had an objection to taking individual cars of varied makes, and the German automobile manufacturers protested against Belgian machines being used while they were in a position to produce.

As early as 1915 the effect of the blockade showed itself in a reduction in the number of German touring cars in service. While in 1914 every officer appeared to be able to get the use of a car, in 1918 the restrictions were so great that in the whole of Brussels, which was the center of the German army organization, there were not more than 50 military automobiles in service. The trolley cars were kept running, and officers used these for getting about Brussels.

The loss of rubber was a serious blow. While the Allies ran all their trucks on rubber tires, and even had automobile-hauled gun carriages rubber shod, the tire dimensions going as high as 60 by 9 in., it was a rare occurrence to see a German truck with rubber tires. Of the hundreds of abandoned or captured German trucks I examined in Belgium, not more than a dozen had rubber tires.

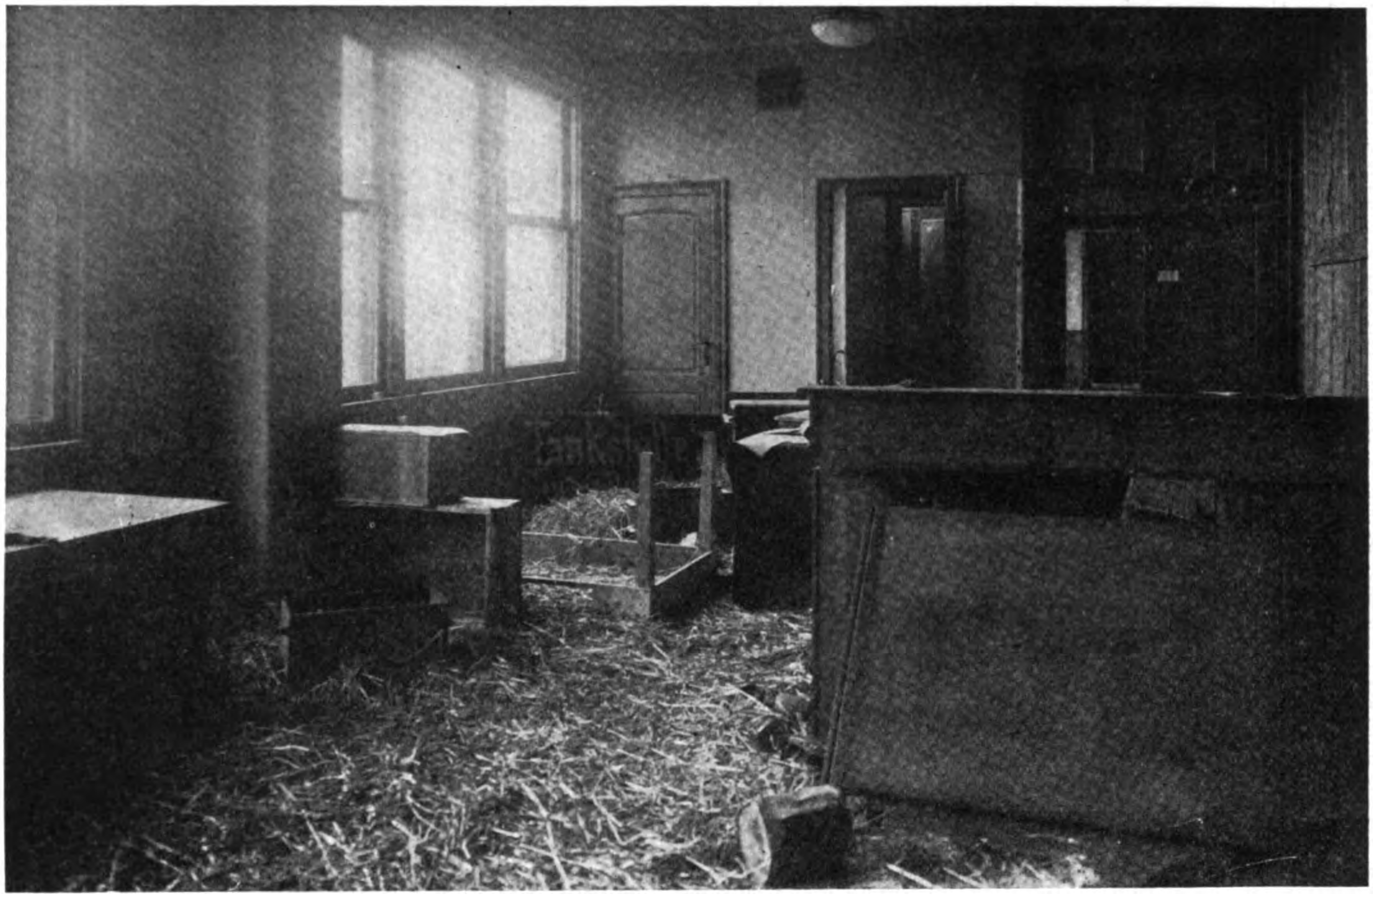
The stories of artificial rubber appear to be a myth. The majority of these trucks had very thick wood rims; mounted on the rim of the wheel around this was a light steel rim which made contact with the road. Another equally common method was a series of rubber blocks, each of which was set in a pair of cups mounted respectively on an inner and an outer rim. The inner rim was fixed and the rim had a certain amount of elasticity. In this case, as in the first instance, a steel rim was in contact with the road, the rubber giving a cushioning effect without being subject to friction with the road surface.

In some instances this system of rubber blocks between two steel rims was applied to touring cars. The result, however, was not at all satisfactory; speed had to be kept down to 12 miles an hour, the vibration was tremendous, and there was a decided tendency to skid.

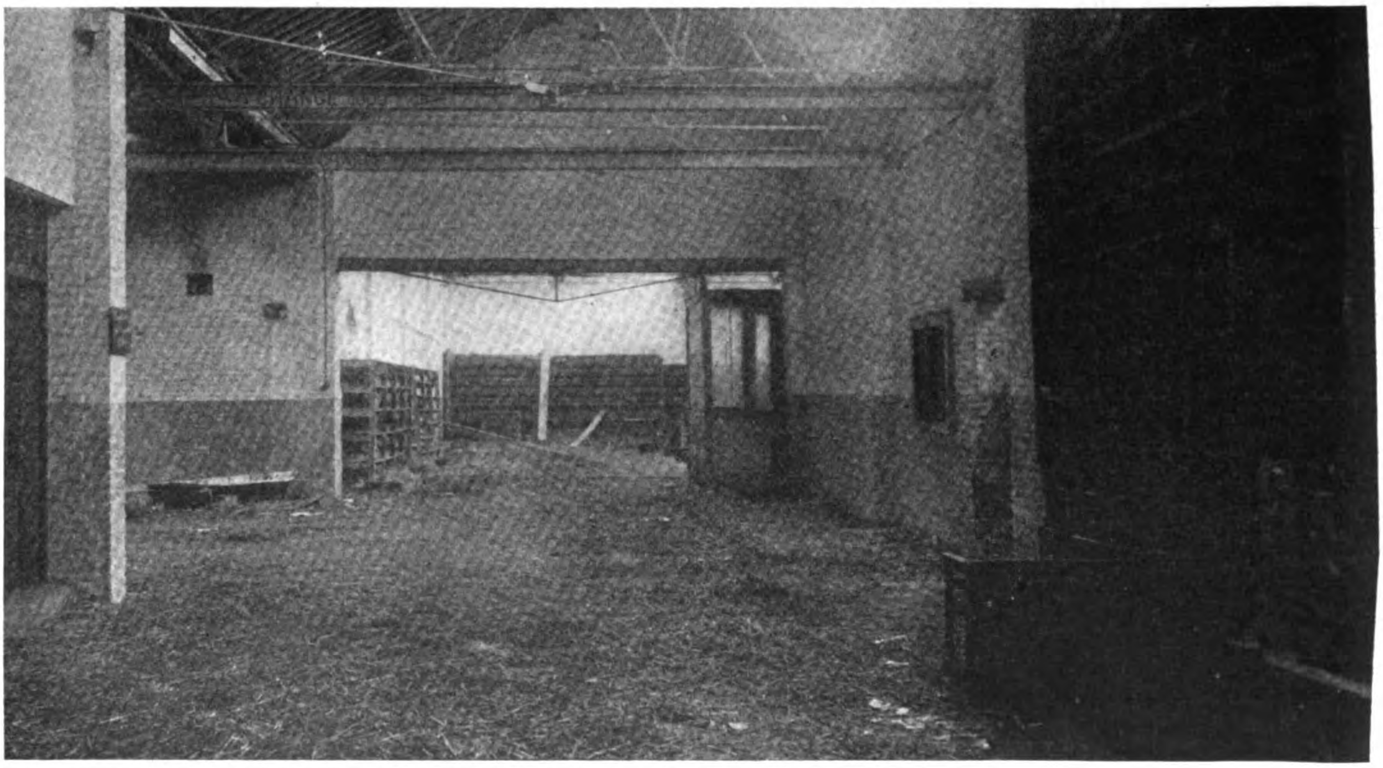
Trucks with steel tires in contact with the road were very difficult to handle on the granite-paved roads of Belgium, and on ice or snow-covered macadam roads. As a precautionary measure, every German truck carried two large sand boxes just behind the rear wheels and under the body overhang.

Sufficient pneumatic tires were obtainable to supply the cars used by the higher staff officers at the front, but the scarcity of rubber and the impossibility of find-

Armistice Day Photographs in the Derihon Factory



The office furniture was smashed, apparently without cause



This stockroom was used as a stable after everything but a weighing machine was removed

ing a substitute for pneumatic tires restricted the use of touring cars to officers in the field.

The truck was maintained by reducing the average speed, but even with this precaution the results were so unsatisfactory that light railroads were preferred. Fortunately for the enemy, Belgium and northern France were well provided with these roads.

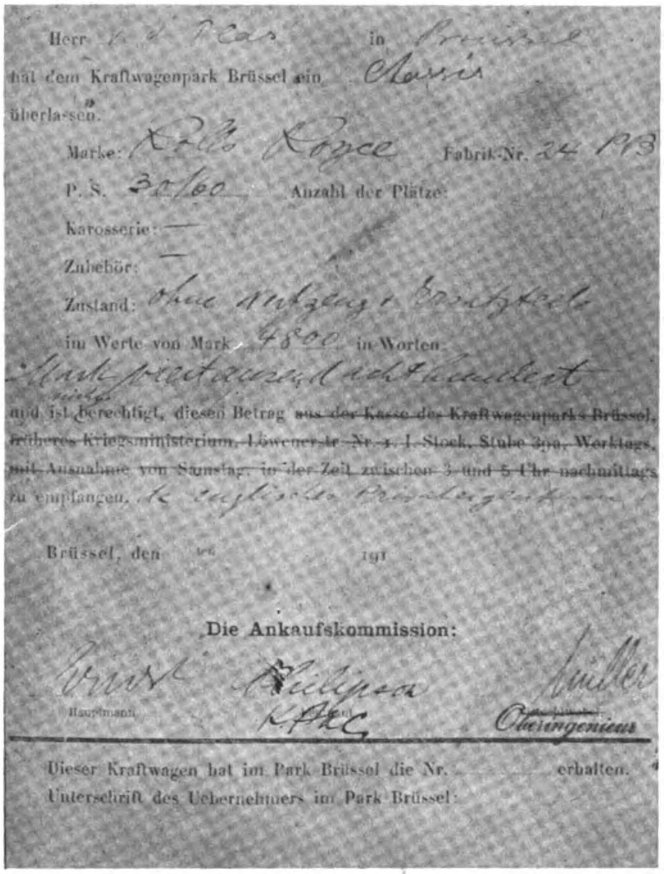
The impression has prevailed that Germany was well provided with gasoline. This is not borne out by automobile engineers who remained in Belgium during the occupation. The Galician and Roumanian oil fields appear to have supplied the enemy little of this fuel. At a comparatively early period restrictions were placed on automobile travel, as much with a view to economizing gasoline and oil as to save rubber.

All gasoline appears to have been reserved for the air service, leaving a peculiar kind of benzol for trucks and touring cars. Although this was officially known as benzol, one engineer, who had an opportunity of using it within a few days of the departure of the Germans, stated that it was a very heavy fuel, of a yellowish tint, having a strong smell of unwholesome eggs. The consumption of this fuel was high. On the dashboard of certain 2-ton trucks the following direction was painted: "Gasoline consumption 80 liters per 100 kilometers," which is equivalent to 3 miles per American gallon.

One of the results of the war has been a serious deterioration of Belgian roads. All the macadam roads have broken down under the strain, for the German armies did as little road repair work as possible. The main roads, paved with granite blocks, were not seriously damaged during the occupation. Since the German armies left Belgium, the civilian authorities have attacked the road problem, and are widening and repairing the main roads to meet the increased traffic which is anticipated with the return to normal conditions.

The Germans made considerable use of trailers for cargo-carrying purposes, for ambulances and for kitchens. All of these were shod with steel tires. While the automobile service was reduced to the lowest possible limits, the railroads were operated to maximum capacity. At certain times there passed over the main lines a train every 5 minutes in each direction, this continuing day and night for two weeks.

When troops were being moved at this rate it was impossible to understand anything of the German plans. When fresh troops were brought from the east the trains appeared to carry an almost equal number of tired troops to the rear. In other words, the movement was so intense in each direction that nothing of the German plan could be ascertained. It was different, however, when a big offensive was in preparation, for when shells were carried to the western front the trains always returned empty.



Herr in
hat dem Kraftwagenpark Brüssel ein Chassis
überlassen.
Marke: Rolls Royce Fabrik-Nr.

Unterschrift des Uebernehmers im Park Brüssel:

Receipt given by the Germans for a new Rolls-Royce chassis requisitioned by them at the Van den Plass body works. They allowed 4800 *marks (approximately* $1,200*). The pre-war value was* $6,000 *and during the war rose to* $9,000

Gasoline tractors were used for hauling big guns. These were mostly manufactured by the German Daimler, Benz, and Horsch companies. In all cases they were of the rear-wheel-drive type, with very large diameter wheels, shod with steel tires. Use was also made of big two-wheel trailers carrying a Mercedes four-cylinder engine of about 5 in. bore, which operated a winding drum, and appeared to be used exclusively for placing the big guns in position. A large number of these, in good condition, were left at the Cockerill Engineering Works.

The Belgian manufacturers have before them a big problem, which they are pluckily undertaking. The destroyed plants are only a part of this task.

Labor conditions in Belgium are in a complex condition as the result of the war. Idleness is always demoralizing, even if adopted to hinder or injure an enemy. Belgian workpeople who have been living on 40 cents a day for 4 years, paying no rent, drawing free soup and rations, stealing from the Germans whenever possible and glorying in the action, are obviously not better for these practices. On the other hand, numbers escaped to England, where they earned high wages and enjoyed better working conditions than ever before in their lives.

These form the two extremes: the men who have been spoiled by prosperity in England and those who have been demoralized by German severity. Between them are the more intelligent and patriotic workers who realize that it is necessary to put forth enormous efforts to return Belgium to her former position.

As in France and England, the claim has been made for an 8-hour working day or less. Even in France it is recognized that the reduction in the number of hours can only be effected by the use of labor-saving machinery and better shop methods. Directors of small French industries, in which the proportion of labor to machinery is necessarily high, claim that they are seriously handicapped in comparison with the big industries in which labor is small in proportion to machine work. Until machinery can be obtained for the Belgian factories, hand work will predominate, and because of this condition the manufacturers have opposed the demand for the 8-hour day.

A compromise has been arrived at whereby the 9-hour day will be established for 1 year.

Types of Wanton Destruction by the Germans

The Germans worked until the armistice became effective adding to this pile of scrap. Most of it was made from machinery

Air Weight and Volume Measurement

Practical Use of Venturi Meter for Quantitative Determination — Graphic Methods Shorten Process of Obtaining Results and Permit of Rapid Checking During Tests

By Don T. Hastings

THE apparatus and methods described in this article greatly facilitate the making of tests and the solution of problems in which the measurement of weight or volume of air is involved. Such problems include the determination of mixture ratios delivered by carbureters, division of total air entering a carbureter between the various intakes, volumetric efficiency of engines and the influence of changes in design in valves, valve timing, gas passages, etc., on the volumetric efficiency.

THE accurate and rapid determination of volumes and corresponding weights of air presents a most difficult problem, because of the intangible nature of the material in question and its variations with respect to temperature, pressure and humidity. The effects of these three variables on the density, or weight per cubic foot of dry air, have been carefully determined, and the results are embodied in the Smithsonian Tables; consequently, if a means is found for determining either the volume or weight of a given amount of air the other quantity can be readily computed.

There are three principal methods used commercially or in the laboratory for the measurement of air volume, namely:

A—The gasometer.
B—Orifices in thin plates.
C—The venturi meter.

Of the three the venturi meter is the most accurate—the readings given by either of the other two devices being based on an initial calibration, while those of the venturi meter depend solely on its size and proportions.

The Venturi Meter

The venturi meter is an instrument for the measurement of the quantity of liquid or gas which flows through a pipe and consists essentially of a piece of round straight pipe which is contracted for a short distance to a diameter smaller than the main part of the pipe. The decreased diameter is known as the throat, and for convenience is usually made one-half, one-third or one-fourth the diameter of the main pipe; the length of the throat is usually made equal to its diameter and it is connected to the main pipe at each end by conical sections, which for the best results should have an included angle of 5 deg. to 11 deg., the smaller angle being the best. All the inside surface should be machined smooth so that there are no shoulders to interfere with the flow. Connections for manometers or gages for determining the pressure in the pipe are made at the throat and at both up and down stream ends a short distance from the ends of the tapered sections.

About 2 yr. ago it became necessary for the writer to determine the mixture proportions furnished by a number of carbureters. Being familiar with the work done by Prof. Charles E. Lucke along similar lines in the laboratory of Columbia University, his advice was followed in designing and constructing a multiple venturi meter to measure the weight of air, while the weight of fuel was determined by means of a tank mounted on an accurate platform scale.

The general layout for the air measurements was as follows:

A Root blower driven by a variable speed electric motor was arranged to draw air either from the laboratory or from outside the building and force it into a header into which the five venturi tubes were connected. From a duplicate header at the other end of the venturi tubes the air was conducted to a large air-tight box in which the pressure was maintained within one-tenth of an inch of water of atmospheric. In addition to varying the speed of the electric motor to secure this pressure relation, the blower was provided with a by-pass and automatic regulating valve.

Arrangements were made either to place the box around the carbureter or to connect the intake of the carbureter to the box by pipe of ample diameter, depending on the nature of the test being run. Every precaution was taken to prevent leakage at any point, although as the pressure in the box was maintained at atmospheric, there was practically no chance of leakage around the box affecting the results. To insure air entering the carbureter under normal conditions, that is, from a state of rest, several baffles were provided inside the box.

The construction of the multiple venturi meter is shown in Fig. 1. Five venturi tubes, each having a ratio of throat diameter to upstream diameter of one to two, were arranged between two headers of large diameter pipe. The throat diameters from top to bottom were ¼ in., ⅜ in., ½ in., ¾ in., and 1 in. Each end of each venturi tube was connected to a piece of iron pipe whose inside diameter was approximately the same as the upstream diameter of the venturi, in order to insure smooth flow and avoid eddy currents in the instruments. Between each of these pipes and the header were inserted a tee and a quick-acting shut-off valve. In addition, the three center venturis were provided with expansion joints to facilitate the assembling and avoid strains which might possibly result in air leaks.

The purpose of the shut-off valves at the upstream ends of the pipes was to permit the use of one or more venturis at a time, as required by the amount of air to be measured. The valves at the discharge ends of the

pipes, in connection with the adjacent tees, permitted two or more measurements to be made at the same time, as, for instance, the amounts of air entering a carbureter at the main and auxiliary intakes. In this case a second large box was provided to which the auxiliary intake was connected. The pressure in the second box was regulated to atmospheric by partially closing the valve at the entrance to the venturi thus used.

The venturi tubes proper were made of non-corrosive bronze and most carefully machined, so that the sizes were exact to less than 0.001 in. The workmanship was excellent, as no difficulty was experienced in maintaining the metal to metal joints airtight. Each venturi consisted of the following: 1 throat; 2 duplicate tapered sections; 2 duplicate upstream (and downstream) sections, and 2 duplicate pipe flanges. As the result of this design the throat for the ½-in.-1-in. venturi was the same as the upstream section for the ¼-in.-½-in. venturi, and the same relation existed between other sizes. The tapered sections also were made in such lengths that two or more could be joined together in case ratios other than one to two were desired between throat and upstream sections. This made a number of duplicate units so that the parts were readily manufactured, and the resulting outfit was quite flexible.

Each throat (or upstream section) consisted of two pieces. The throat proper, which was simply a ring of the proper inside diameter and length, had a groove turned around the outside at about the center of the length. From this groove four small holes were drilled through to the inside at 90-deg. intervals. The outer piece was also a ring which was a shrink fit on the throat proper. This outer ring was provided with four tapped holes for manometer connections. In assembling the two rings the tapped holes were carefully lined up with the drilled holes, so that the latter could be readily cleaned out if necessary. This construction gave an annular chamber around the throat connected at four points to the inside of the throat, thus insuring the pressure delivered to the manometer being as truly representative of the actual average pressure in the throat as possible.

The tapered sections and pipe connections were each provided with heavy flanges drilled for four bolts. The throat and upstream sections were thus clamped solidly between the two adjacent flanged pieces, making the construction very rigid and yet easily demountable when required. The clamp bolts (or their center lines) are shown in Fig. 1 only on next to the bottom venturi for the sake of clearness.

The Manometers

Previous experience with the ordinary U-tube water manometer for determining pressures led to the decision to design and construct special single-tube manometers. Special, heavy-wall, uniform-bore glass tubing was obtained, and connected top and bottom to specially designed castings, all being mounted on suitable boards for handling. The lower casting had a horizontal internal area of about 4 sq. in., while the bore of the tube was about ⅛ in. This gave a ratio of areas of about 1 to 340, and, consequently, a drop of level in the reservoir of this fraction of the height to which the column rose in the tube. By calibrating the manometer scale to allow for this drop, direct readings of height were made possible, in place of the customary two readings to be added, as in the case of the ordinary U tube.

A screw plunger for adjusting the level to zero of the scale was provided in the lower casting, similar to that found on barometers. The lower casting was also provided with a suitable drain cock, and a needle valve connection between the reservoir and the water column. Partially closing this valve assisted materially in steadying the height of the water column in case the pressure fluctuated slightly. At the same time it did not restrict the passage sufficiently to render the readings inaccurate.

The pressure connection to the reservoir was made by a special nipple and a tube carried up to the level of the top of the instruments to prevent spilling when the instrument was inclined and also to facilitate the making of connections.

The upper casting had a capacity in excess of the total volume of liquid used in the instrument to prevent over-

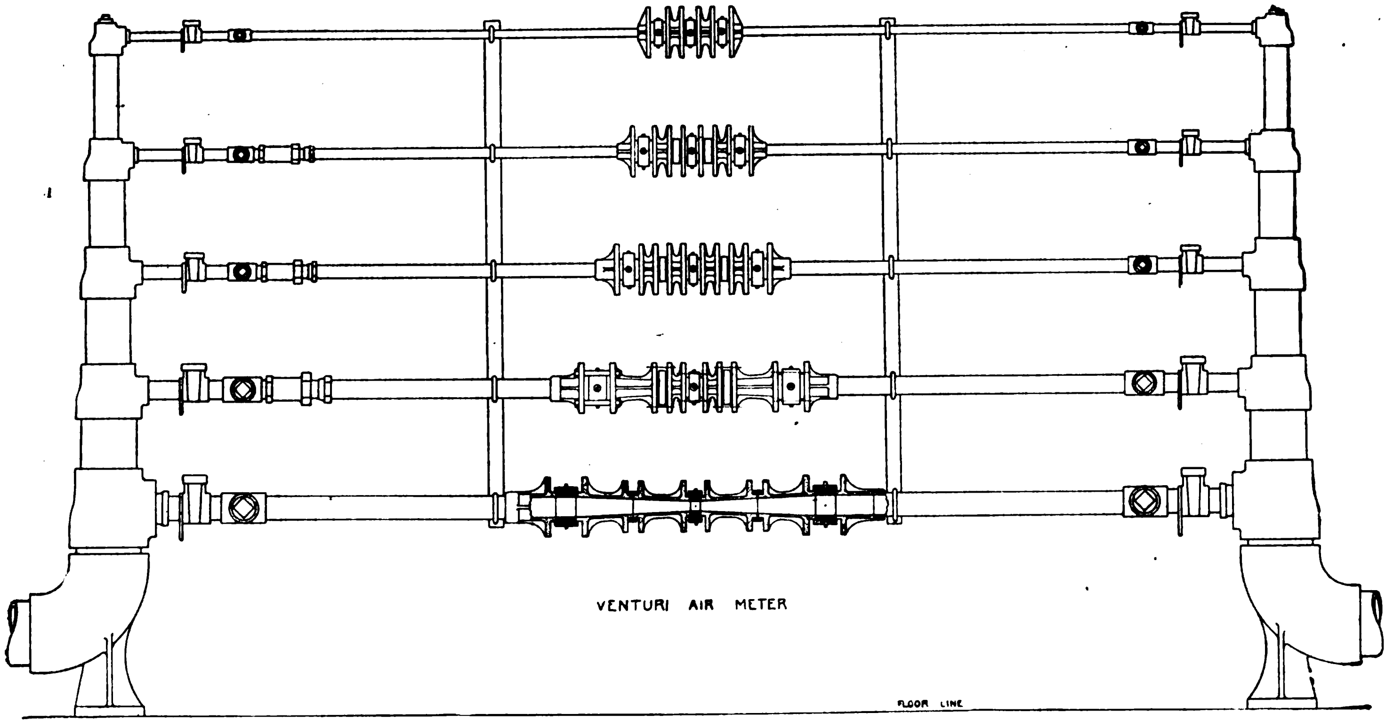

Fig. 1

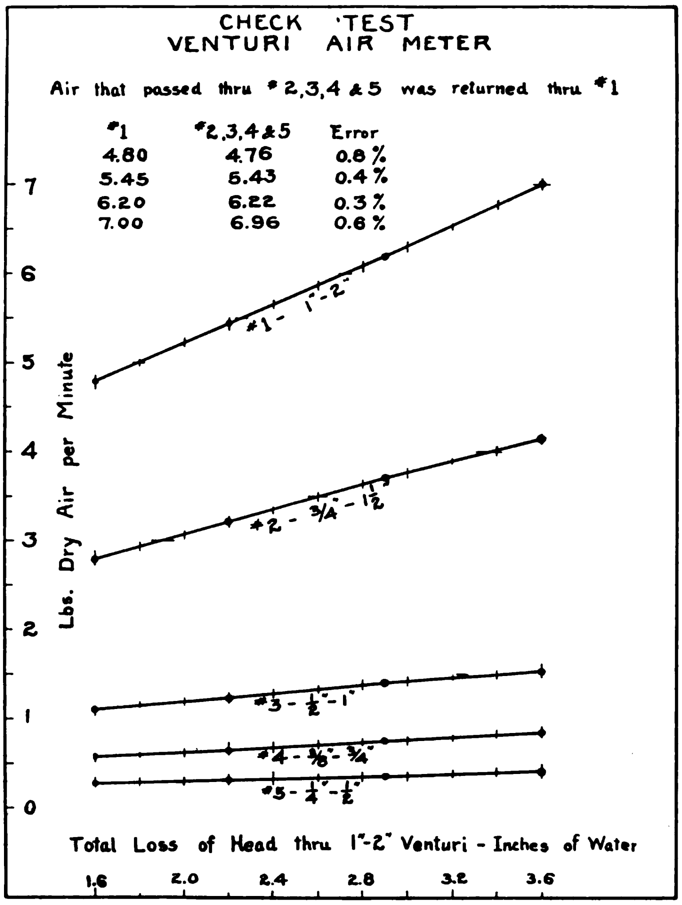

Fig. 2

flow in case excessive pressure was unexpectedly encountered. It was provided with a large filling plug and a suitable vent arranged to prevent the entrance of dirt. The shape of the upper casting and its connection to the top of the tube were so made that no liquid could be trapped and eventually work down to interfere with the accuracy of the readings. The vent could be readily replaced by a nipple for connection to a second source of pressure, in case it was desired to determine the difference of two pressures directly, instead of merely a pressure above atmosphere. This connection was also used if the instrument was needed as a suction gage, the vent then being through the tube leading down to the top of the lower casting.

Iron castings were used in the manometers, as they were sometimes used with mercury instead of water as the liquid. Brass would ordinarily be the better material where water only was to be used, but is impossible with mercury, due to the alloying action. No trouble was experienced with the cast iron in the water manometers, it merely being necessary to drain and rinse the instruments occasionally as the water became fouled with rust.

To insure the maintenance of atmospheric pressure in the box surrounding the carbureter a differential or inclined tube manometer was used. This is an ordinary manometer with the tube set at an acute angle with the horizontal instead of vertical. The result is to increase the movement of the liquid for a given vertical rise, permitting more accurate readings of small pressure differences. If the tube is set at 30 deg. with the horizontal the travel of the liquid along the tube is twice the vertical rise, while smaller angles give proportionately greater ratios.

As soon as the meter and blower were installed and all air leaks at pipe joints, valves, etc., eliminated, a check was made of the instrument by closing the end of the discharge header and the inlet valve to the largest venturi and removing the plug from the tee close to this valve. Air was then forced through the four smaller venturi tubes, all this air, of course, being obliged to return through the largest venturi. The results obtained are shown in Fig. 2. It will be noted that the difference for each set of readings was less than 1 per cent, indicating that the instrument is sufficiently accurate for all ordinary purposes.

The test described above is, of course, not an absolute check. An accurate check of this instrument could only be made by determining the actual weight of air, which is an extremely slow and expensive process. It was considered entirely unnecessary, however, as tests made at various places in the past have shown accuracies in the neighborhood of 99.8 per cent to 99.9 per cent. Some of these tests are described in Prof. Lucke's book, "Thermo-Dynamics."

To determine the loss of head through the instrument, a test was run whose results are shown in Fig. 3. Pressure readings were taken at the downstream end as well as at the upstream end and throat. It will be noted that the pressure loss is very small, indeed, considering the amount of air and the absolute pressures involved.

Use of the Meter

In actual use the meter permitted results to be obtained very rapidly. A few sample charts of tests made are reproduced herewith. Fig. 4 shows the mixture ratios delivered by a commercial carbureter under five different conditions of throttle opening. The wide variation as the quantity of mixture increases is, of course, very objectionable. This particular carbureter had an auxiliary spring-controlled valve. Adjustment of the

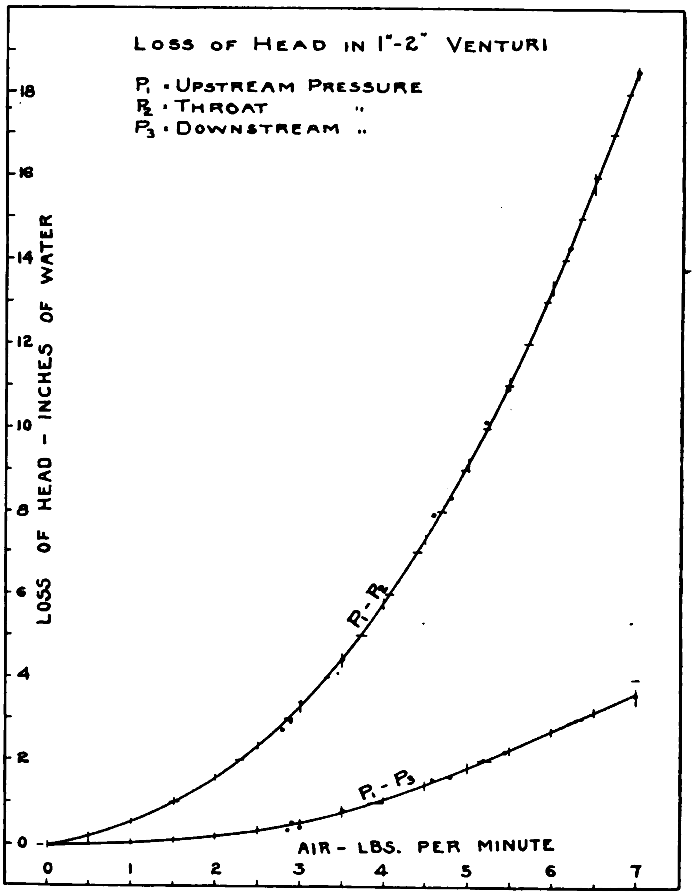

Fig. 3

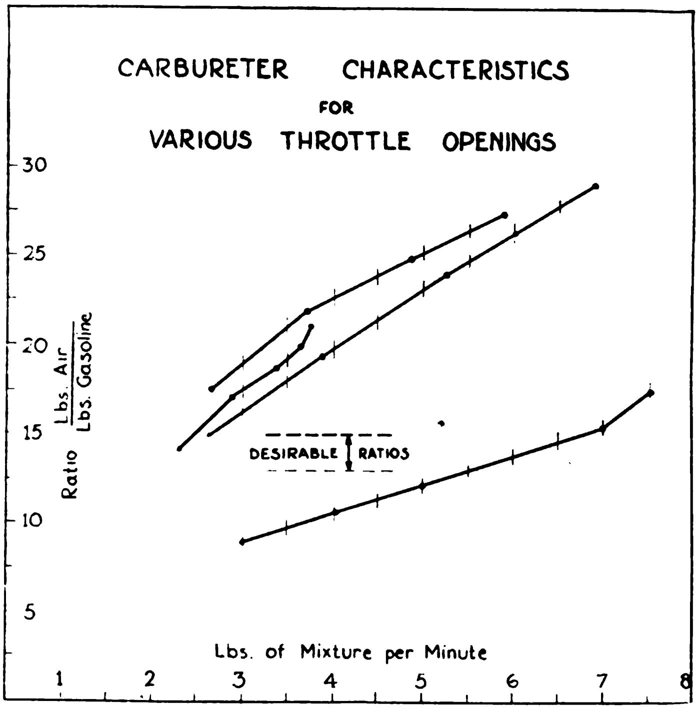

Fig. 4

spring would undoubtedly reduce the variation somewhat—the chart was selected merely to show the striking results obtained.

The test reported in Fig. 5 was made with the two pressure boxes as described above. The carbureter was of the type in which the fuel is atomized by the primary air, the quantity of fuel used being determined by the suction in the primary air passage. This chart, in connection with one like Fig. 4, furnishes an excellent guide to the changes or adjustments required to secure uniform mixture proportions throughout the speed and load range above idling. It seems to be generally accepted that a slightly richer mixture is desirable for idling, due probably to the greater dilution of the incoming mixture by the gases remaining in the cylinder.

Another very interesting test to which the venturi meter lends itself readily is the determination of volumetric efficiency of internal combustion engines, that is, the percentage of the piston displacement filled by air at atmospheric pressure under various working conditions. The amount of air is compared directly to the piston displacement, neglecting the volume of the fuel, as our present-day fuels generally enter the engine cylinders in a liquid state, even though finally subdivided by the spraying or heating in the carbureter or manifold. The volume occupied by the fuel under these conditions is relatively so small that no serious error is caused by this assumption.

The results of a test of this nature are shown in Fig. 6. A well-known truck engine, which gives general satisfaction, was tested with wide open carbureter throttle and again with the carbureter removed, the intake manifold being connected directly to the pressure box of the venturi meter. A surprising difference in the percentage of cylinder volume filled is at once apparent. It is evident that up to about 1200 r.p.m. the size and timing of the engine valves, shape and size of gas passages, etc., are about as good as it is possible to get. The one reading taken above 1200 indicates a fairly rapid falling off in efficiency at higher speeds. This is entirely immaterial, however, as the governed speed of this engine is in the neighborhood of 1050 r.p.m.

The striking thing about this test was the serious drop in volumetric efficiency when the carbureter was in place. The indications are, of course, that a larger carbureter is desirable. Before such a conclusion is accepted, however, the fuel consumption per brake horsepower hour with both carbureters should be checked up, as it is probable that the larger carbureter would give increased fuel consumption. Another factor to be carefully considered is whether the increased power is really desired. The engine is, of course, a heavy-duty one, and the power produced may be ample for the truck in which it is mounted. In any case, the increased power would undoubtedly mean shorter life and, consequently, greater repair expense and depreciation. All these factors must be taken into consideration before a change is made. Tests of this nature, however, are of considerable value in comparing different carbureters and in studying the effect of different size valves, changed valve timing, etc.

Data Required

The data which must be obtained whenever the air meter is used are shown in Fig. 7 in tabular form. This includes only the air meter data for a simple test, such as that charted in Fig. 4. The data sheet must be amplified in any particular case to include the other variables, such, for instance for Fig. 4, as fuel consumption and r.p.m.

The two temperatures and the barometer reading are used in determining the density of the air, and the barometer equivalent in inches of water, the two pressures and the two areas in determining the weight flowing per minute.

The data in connection with the density must be obtained to correspond with the air used; that is, if the air is drawn from outside the building the readings

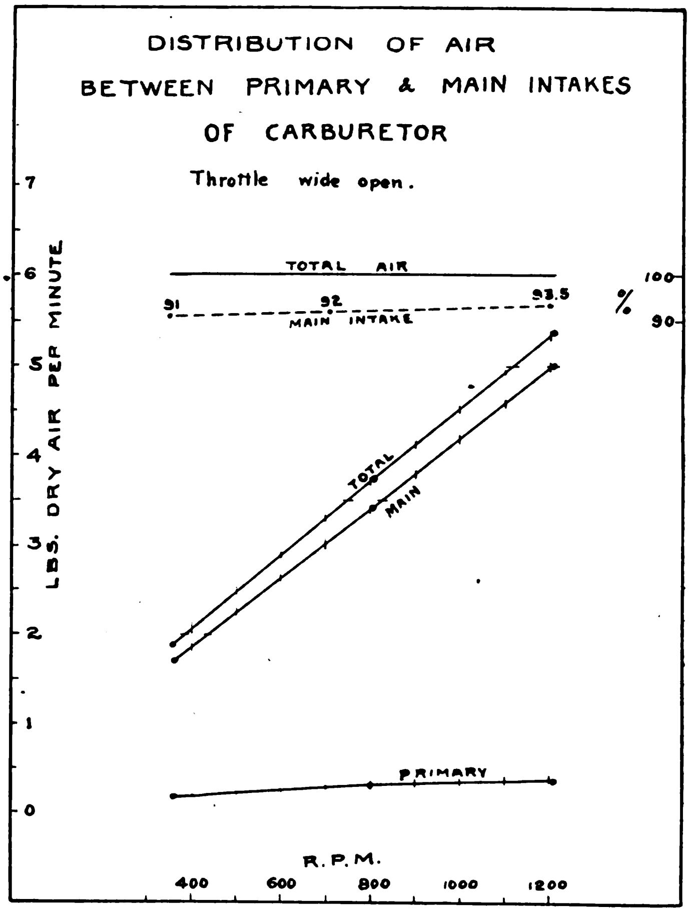

Fig. 5

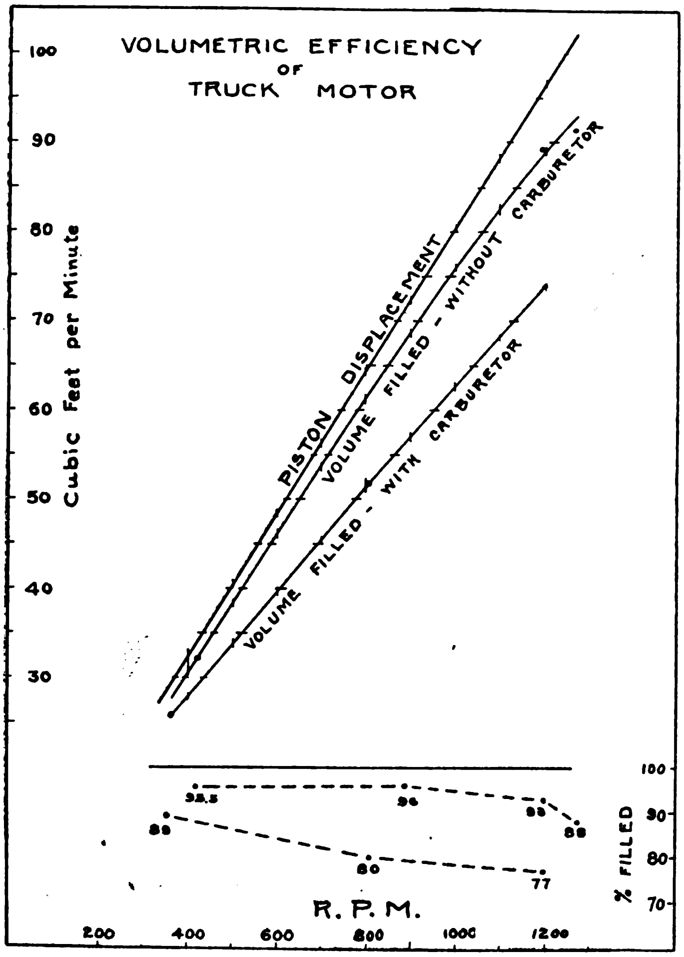

Fig. 6

should be made outside, while if air is drawn from the laboratory the readings must be made there.

The air temperature can be determined by means of any accurate Fahrenheit thermometer, readings being taken to the nearest ½ deg. The web-bulb thermometer readings are best obtained by means of a whirled sychrometer, which consists essentially of a Fahrenheit thermometer so mounted in a case that its bulb is surrounded by a cloth whose lower end is immersed in a vessel of water. This keeps the cloth around the bulb moist. The instrument is used by being swung around or to and fro at a velocity at the bulb of at least 10 ft. per second. This is the minimum velocity for accurate results—greater velocities make no appreciable difference in the readings. The temperature should be noted before starting to swing the instrument and then at short intervals until it has ceased to drop, the final temperature being recorded as t_1 in the tabular form.

Data for determining density should be obtained about each half hour at the start of a series of tests, particularly if made in a room whose temperature rises during the test, as, for instance, when an engine is being run under its own power. After three or four readings have been taken, the frequency may be decreased if conditions are found to remain substantially constant.

Computations and Charts

The computation of results, even though use is made of logarithms, is an extremely slow and laborious process, due to the complexity of the formulæ, and presents constant opportunities for errors in calculations. It has the additional disadvantage of postponing the comparison and interpretation of results until a test is completed. If one set of readings is then found to give a result widely at variance with the others, either this result must be discarded or the whole test repeated. Obviously, then, it is of great importance to be able to obtain the results immediately after a set of readings is taken. To permit this being done, the charts shown in Figs. 8, 9 and 10 were prepared. While at first glance these charts seem quite complicated, with a little practice it is possible to obtain the result of a set of readings from them in 20 to 30 sec. as compared to about ½ hr. for the straight computation.

The charts are believed to be quite accurate. In Fig. 8 the lines carrying Roman numerals correspond to the data $b = 29.5$, $t = 82$ deg. Fahr., $t = 71$ deg. Fahr. The value of d from the chart is 0.0707 lb. per cu. ft., which agrees almost exactly with the computed value 0.07066. In Fig. 9 the data being $d = 0.0795$, $P = 380$ and $P = 390$, the chart gives $d = 0.081$ as against a computed value of 0.08099, a difference of less than 0.02 per cent. Also, in Fig. 9, V from $W = 0.7$ and $d = 0.070$ shows 10 cu. ft., which is obviously correct.

The data shown in Fig. 10 by the circles is $P_1 = 396$, $P_2 = 389$, $\frac{A_2}{A_1} = 200$, $d = 0.089$ and $A_2 =$ the area of a circle 1 in. in diameter. The chart gives a weight of 4.75 lb. per min., while the computed weight is 4.767, an error of less than 0.4 per cent.

SYMBOLS

d = density of dry air in pounds per cubic foot.
t = temperature of air in degrees Fahrenheit.
t_1 = temperature of wet bulb thermometer in degrees Fahrenheit.
b = height of mercury barometer in inches.
f_1 = vapor pressure in inches of mercury of saturated air at temperature t_1.

TO USE CHART

Vertical lines are numbered 1-15 in order of use.
Locate from data points on lines 1, 2, 5, 9 and 14.
Locate points on other lines by construction lines I-VIII as follows:

I through 1 and 2 locates 3.
II transfers 3 to 4.
III through 4 and 5 locates 6.
IV through 6 and zero of 7 locates 8.
V through 8 and 9 locates 10.
VI through 10 and zero of 11 locates 12.
VII transfers 12 to 13.
VIII through 13 and 14 locates 15.

NOTES

Significance of lines is as follows: 4—Smithsonian Table 41; 5—Smithsonian Table 40.
Intersection of IV and 5 shows vapor pressure on left and corresponding dew point on right.
Calibration of 14 is from Smithsonian Table 81.

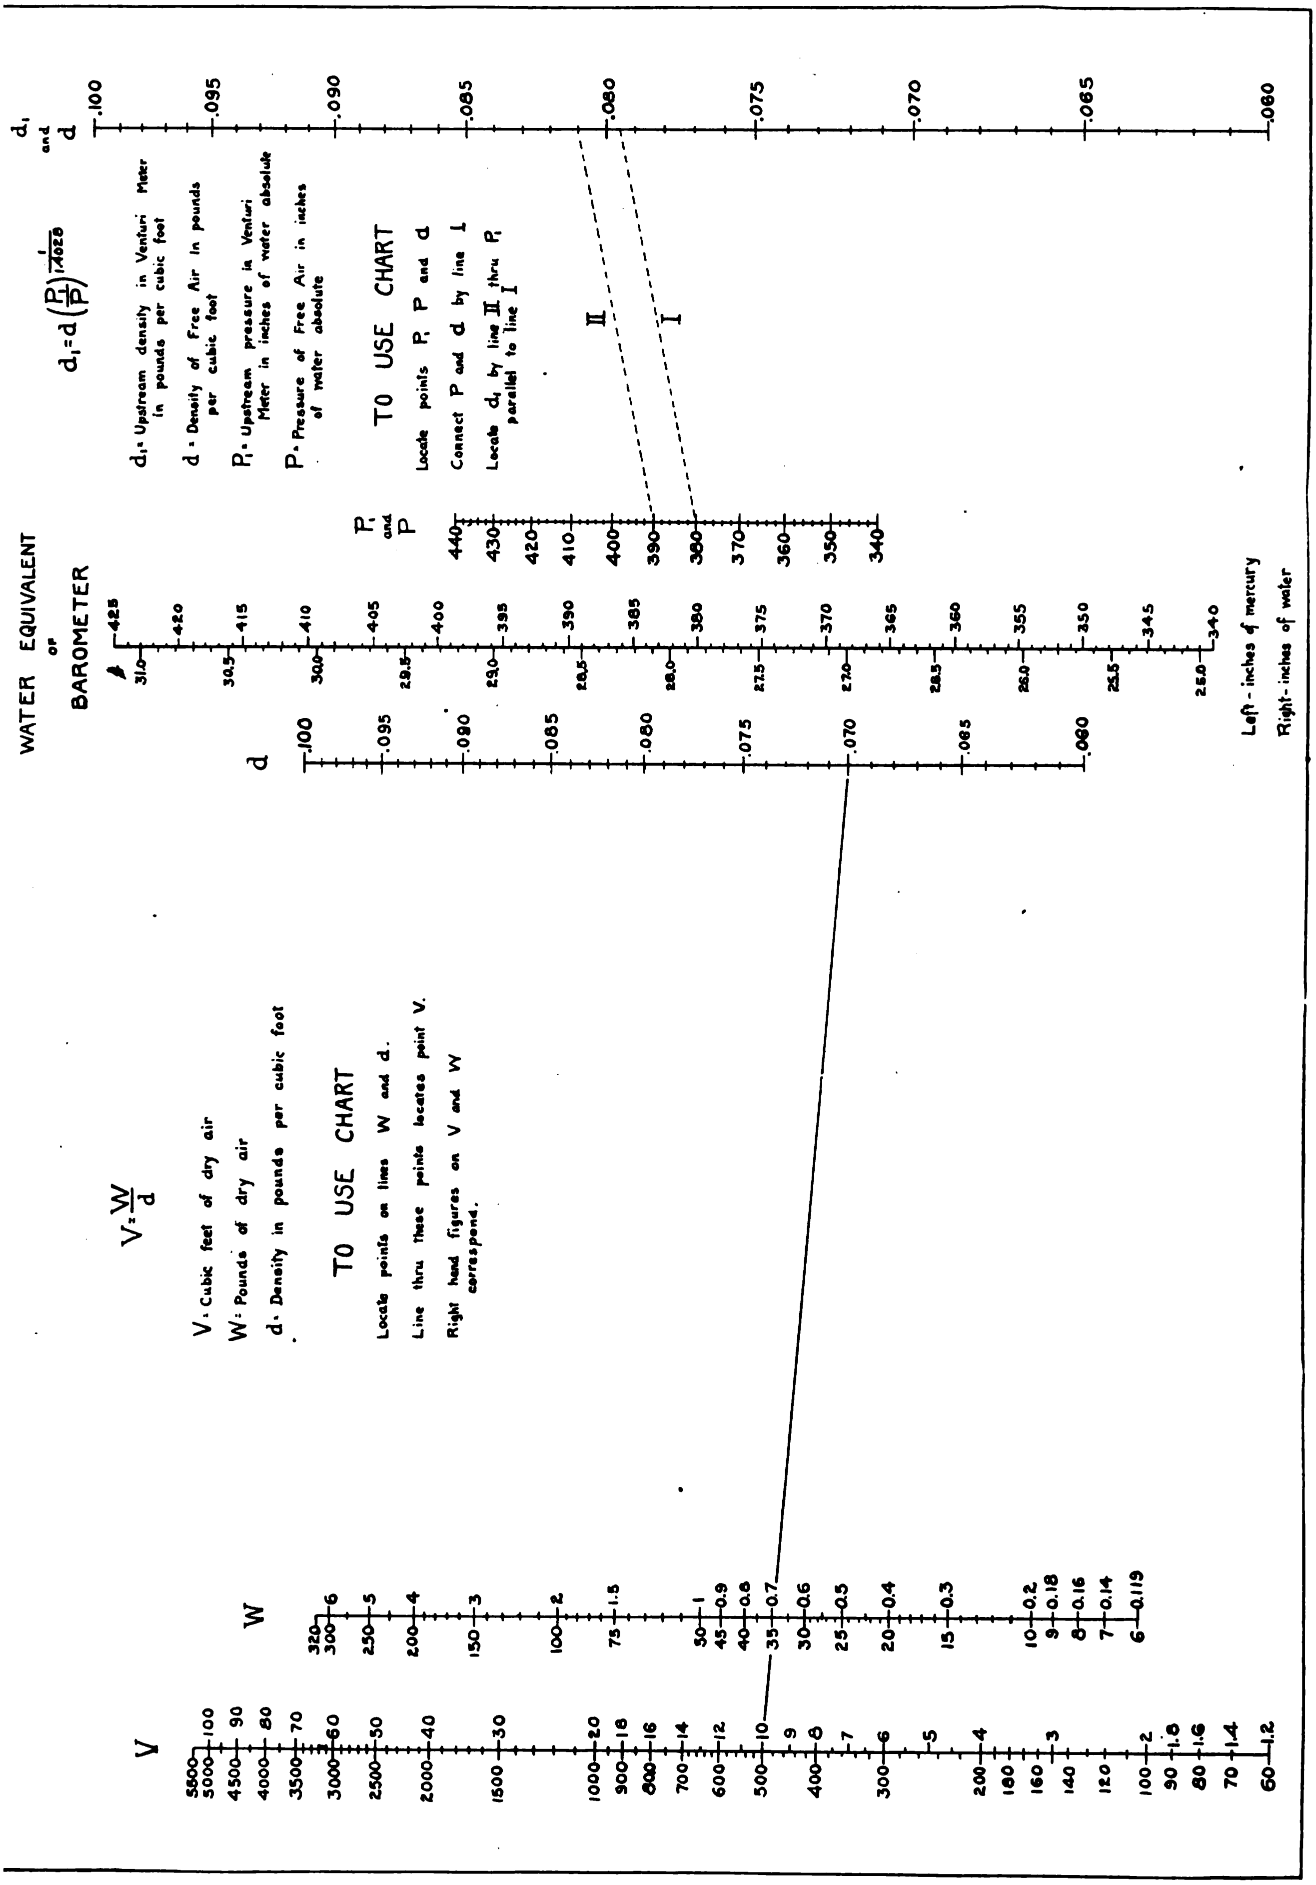
MOIST AIR

To obtain density of moist air use line 10 M instead of line 10.

The density of the air where the sychrometer readings were taken is readily determined by reference to Fig. 8, complete directions for the detail use of the chart being given thereon. It may be of interest to note the significance of the several lines and their correspondence to some of the Smithsonian Tables. It must be clearly understood that the density obtained from this chart is that corresponding to atmospheric pressure. It is not the density of the air in the upstream section of the venturi which is required for use in Fig. 10.

This upstream density can be readily determined by reference to the right-hand chart of Fig. 9 and to the barometer conversion chart extending through the center of Fig. 9. The latter gives directly the height in inches absolute of a water column equivalent to the height of the mercury column of the barometer. As will be shown later, extreme accuracy in this conversion is relatively unimportant, and readings of the water column height to the nearest inch are entirely satisfactory. This quantity is P for the calculation of d_1, and is to be added to the upstream and throat manometer readings to get P_1 and P_2 for use in the right-hand chart of Fig. 9 and in Fig. 10. The value of d_1 must, of course, be greater than that of d, as the air in the venturi meter is under pressure.

After d_1 has been thus obtained it may be used in connection with the other data required in Fig. 10 to obtain the weight of air flowing per minute, complete directions being given on the chart for its use. It is perhaps advis-



$d_1 = d\left(\frac{P_1}{P}\right)^{\frac{1}{1.4028}}$
d_1 = Upstream density in Venturi Meter in pounds per cubic foot
d = Density of Free Air in pounds per cubic foot

Figures on line 11 show densities.
Figures on line 13 show diameters.

TO USE CHART

Vertical lines are numbered 1-14 in order of use.
Locate from data points on lines 1, 2, 4, 9, 11 and 13.
Locate points on other lines by construction lines I-VIII as follows:

I through 1 and 2 locates 3.	V through 6 and 7 locates 8.
II through 3 and 4 locates 5.	VI through 8 and 9 locates 10.
III transfers 3 to 6	VII through 10 and 11 locates 12.
IV transfers 5 to 7.	VIII through 12 and 13 locates 14.

Right hand figures on 13 and 14 correspond.

able to call particular attention to the figures given on lines 4, 11 and 13. The decimals on line 4 show the ratios of the areas, while the fractions in parentheses show the ratios of diameters, the three commonest ratios only being thus expressed. Ratios nearer unity than (1/2) are inadvisable, owing to the slight pressure difference and consequent probability of error in readings, while ratios greater than (1/4) make no difference in the figure for the weight, and, consequently, the point on line 4 corresponding to the ratio (1/4) may be used for all greater ratios. It is not actually necessary to compute the areas A_1 and A_2 as the ratio only is required.

$$\frac{A_2}{A_1} = \frac{\frac{\pi}{4}D_2^2}{\frac{\pi}{4}D_1^2} = \frac{D_2^2}{D_1^2} = \left(\frac{D_2}{D_1}\right)^2$$

The square of the ratio of the diameters is much more easily computed and is the same ratio as shown above.

Line 11 is graduated proportional to the square root of d_1, but the figures given represent d_1 directly instead of its root. Line 13 is graduated in proportion to the areas of the throats, but the figures given read in inches of diameter, as this saves the labor of computing the area.

Attention is also called to the limits of the ratio $\frac{P_2}{P_1}$

These are 0.995 and 0.950, as shown by line 3. If the values obtained for P_1 and P_2 give a ratio outside of these limits, a larger or smaller venturi should be used. This illustrates again the extreme importance of obtaining the results at once after the data are recorded, to avoid the recording of unsuitable figures and permit

immediate repetition of a test, if for any reason the results are doubtful.

The left-hand chart of Fig. 9 was added to afford easy means of figuring the volume corresponding to any weight of air. It is required in case, for instance, the volumetric efficiency of an engine is being checked. Care must, of course, be exercised to select the proper value of d. In the case just mentioned it would be the value corresponding to atmospheric pressure and the temperatures t and t_1; that is, the value obtained from the chart in Fig. 8.

The Density Formula

The formula for the density of air in pounds per cubic foot given at the top of Fig. 8 is quite involved. It is based, however, on a few simple facts and its derivation is rather interesting.

The weight of a cubic centimeter of dry air at sea level in latitude 45 deg. and 32 deg. Fahr. is 0.00129305 gram. This value has been determined with great care, and is one of the accepted international standards. Under these conditions the height of the mercury barometer is 29.921 in.

Very carefully conducted experiments have proven that air expands about one-five-hundredth (0.0020389) of its volume at 32 deg. Fahr. for each degree Fahrenheit that its temperature is raised; that is, at a temperature of t deg. Fahr., its volume becomes $1 + 0.0020389\ (t - 32)$ times the volume at 32 deg. Fahr. The weight of a cubic centimeter under these conditions is decreased proportionately and becomes

$$d_t = \frac{0.00129305}{1 + 0.0020389\ (t - 32)}$$

The weight of a cubic centimeter, or, in other words, the density, also varies in direct proportion to the pressure, so that for any pressure H we have the proportion

$$\frac{d}{d_t} = \frac{H}{29.921}$$

from which

$$d = d_t \times \frac{H}{29.921}$$

and substituting our value for d_t

$$d = \frac{0.00129305}{1 + 0.0020389\ (t - 32)} \times \frac{H}{29.921}$$

For our purpose we desire the density expressed in pounds per cubic foot. There are 28,317 cu. cm. to the cubic foot and 0.0022046 lb. makes one gram. The product of these two factors is 62.4283, which, introduced in our formula, gives

$$d\ (\text{cu. ft.}) = 62.4283 \times \left[\frac{0.00129305}{1 + 0.0020389\ (t - 32)}\right] \times \frac{H}{29.921}$$

The factors 62.4283, 0.00129305 and 29.921 could, of course, be combined into a single number (0.00269787), but they are left separate in order to keep the various parts of the formula in the form used in the Smithsonian Tables. The values of the fraction in the brackets above are given for all values of t from -45 deg. Fahr. to $+140$ deg. Fahr. in Table 81. By following this arrangement the checking of values given by the chart is rendered comparatively easy.

This formula is really only a variation of the familiar gas formula

$$PV = WRt$$

in which

P = absolute pressure
V = volume
W = weight
R = a constant depending on the particular gas and the units in which P, V, W and t are expressed
t = absolute temperature

From this, $\frac{PV}{Wt} = R = \frac{P_1V_1}{W_1t_1}$ and $\frac{Wt}{PV} = \frac{W_1t_1}{P_1V_1}$

Substituting the quantities d and d_1 for their equals $\frac{W}{V}$ and $\frac{W_1}{V_1}$ we get

$$\frac{dt}{P} = \frac{d_1t_1}{P_1} \text{ and } d = d_1 \times \frac{t_1}{t} \times \frac{P}{P_1}$$

Substituting our standard condition values for d_1, t_1 and P_1, dividing both numerator and denominator of the second half of the equation by t_1 we get the same result as before.

The pressure H in our formula is that due to dry air only. The actual pressure of the atmosphere as registered by the barometer is greater than the quantity H due to the presence of water vapor in the air. This aqueous vapor exerts a certain pressure e and we have the relation

$$b = H + e$$

in which b = height of barometer.

From this

$$H = b - e$$

which can be inserted in the formula for d for dry air, giving us

$$d = 62.4283 \left[\frac{0.00129305}{1 + 0.0020389\ (t - 32)}\right] \frac{b - e}{29.921}$$

The pressure e exerted by the aqueous vapor in the air has been determined to bear a relation to the barometric pressure and the temperatures as shown by the wet and dry bulb thermometers in accordance with the formula

$$e = f_1 - 0.000367b\,(t - t_1)\left(1 + \frac{t - t_1}{1571}\right)$$

in which

e = vapor pressure in inches of mercury
f_1 = vapor pressure in saturated air at temperature t_1 in inches of mercury.
b = barometric pressure in inches of mercury
t = air temperature in deg. Fahr.
t_1 = temperature by wet bulb thermometer in deg. Fahr.

The values of f_1 are tabulated for all ordinary temperatures in Smithsonian Table No. 40, and it was from this table that line 5 in Fig. 8 was plotted. The values of the quantity to be subtracted from f_1 are tabulated in Smithsonian Table No. 41—values found on line 4 of the chart correspond to this table.

Substituting the above value of e in the formula for d of dry air, we get

$$d = 62.4283 \left[\frac{0.00129305}{1 + 0.0020389\ (t - 32)}\right] \frac{1}{29.921} \left[b - \left\{f_1 - 0.000367\ (t - t_1)\left(1 + \frac{t - t_1}{1571}\right)\right\}\right]$$

This formula for the density of dry air should not be confused with that for the density of moist atmospheric air in which the weight of the moisture is included. The latter formula is very similar, differing only in that the factor 0.378 e is subtracted from b instead of the full value of e being used. This results from the fact that the density of aqueous vapor is expressed by the formula

$$d_{a.v.} = 0.622\left[\frac{0.00129305}{1 + 0.0020389\ (t-32)}\right]\frac{e}{29.921}$$

the factor 0.622 being the specific weight of the aqueous vapor relative to air. It will be seen that the formulas contain several duplicate terms, so that on adding the densities to get the density of the moist air we have

$$be + 0.622e = b - 0.378e$$

in the numerator of the last fraction.

It is, of course, the density of the dry air only with which we are concerned in determining the mixture ratio delivered by a carbureter, as the moisture in the air does not enter into the combustion. On the other hand, in determining the volumetric efficiency of an engine, the density of the moist air should theoretically be used. Practically, however, the error caused by using the density of the dry air is so slight as to be negligible, consequently the chart was prepared for the density of dry air only. The change necessary to obtain moist air density consists in substituting the line 10*M* for the line 10 in locating the point of intersection of lines *V* and *VI* and the chart can be so used if desired.

Densities in Venturi Meter

The density obtained from Fig. 8 is that of air at atmospheric pressure. This quantity cannot be used in connection with the chart of Fig. 10, as the density in any one of the venturi tubes is greater than this amount, owing to the greater pressure in the tube. The compression is assumed to be adiabatic; that is, such that the air does not give up heat to or receive heat from the blower or venturi tube walls, due to the extreme rapidity of flow, and consequently the volumes are related to the pressures as follows:

$$PV^s = \text{a constant}$$

$$\text{Since } d = \frac{1}{V} \text{ we have}$$

$$\frac{P}{d^s} = \text{a constant} = \frac{P_1}{d_1^s}$$

From this,

$$\left(\frac{d_1}{d}\right)^s = \frac{P_1}{P} \text{ and } \frac{d_1}{d} = \left(\frac{P_1}{P}\right)^{\frac{1}{s}}$$

Consequently,

$$d_1 = d\left(\frac{P_1}{P}\right)^{\frac{1}{1.4028}}$$

The right-hand chart of Fig. 9 affords an easy means of determining d_1 ready for use in the chart of Fig. 10. Care must be exercised in case more than one venturi tube is used at the same time to determine the density d_1 for each tube in accordance with its upstream pressure P_1.

Water Equivalent of Barometer

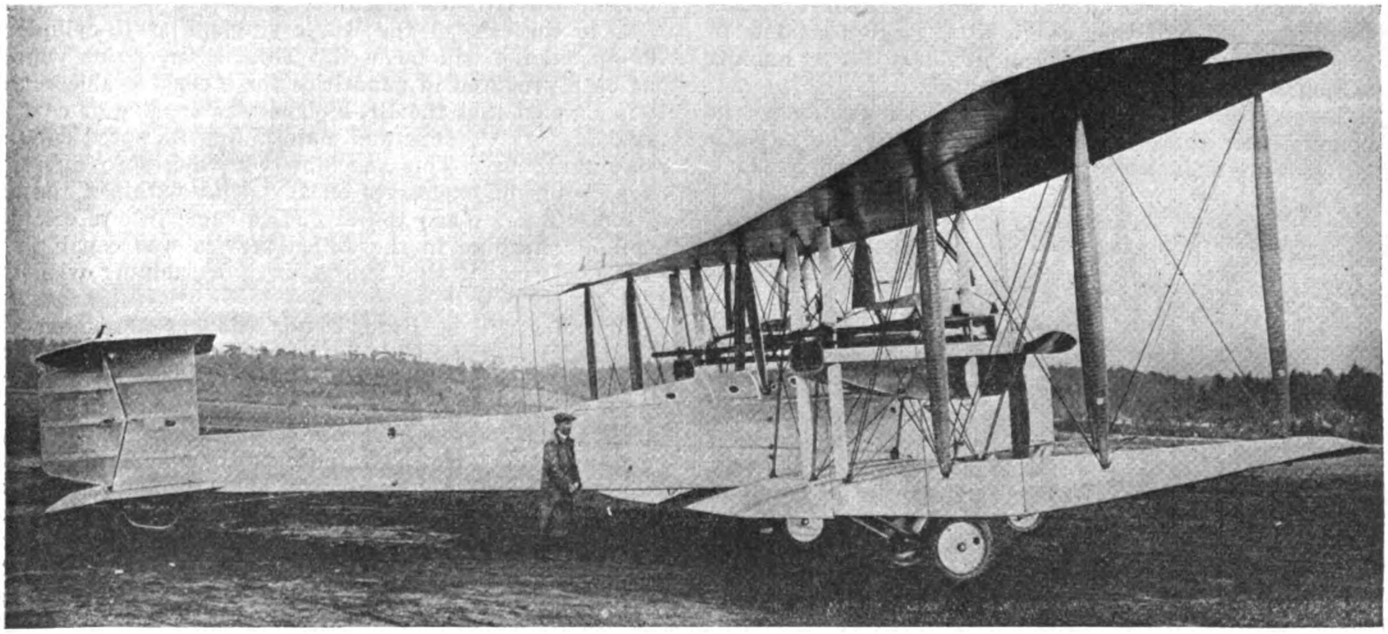
It was stated above that the exact determination of the height of a column of water equivalent in pressure to that of the barometric mercury column was relatively unimportant. This is true only because the factors into which this enters are all expressed as ratios, and, consequently, even a relatively large error affects the result by less than 0.1 per cent. For example, suppose that the equivalent of 29 in. by barometer is read as 395 in. water or as 397 in. water. Assume $P_1 = 20$ in. and $P_2 =$ 10 as read on the manometers. Our ratio of $\frac{P_2}{P_1}$ absolute becomes $\frac{405}{415}$ or $\frac{407}{417}$

These are equal respectively to 0.97590 and 0.97602, which values differ only slightly over 0.01 per cent.

The conversion chart on Fig. 9 is about correct for ordinary room temperatures. As shown above, however, no serious error will be made if the chart is used for any temperature likely to encountered.

(To be continued)

Vickers-Vimy Ready for the Transatlantic Flight

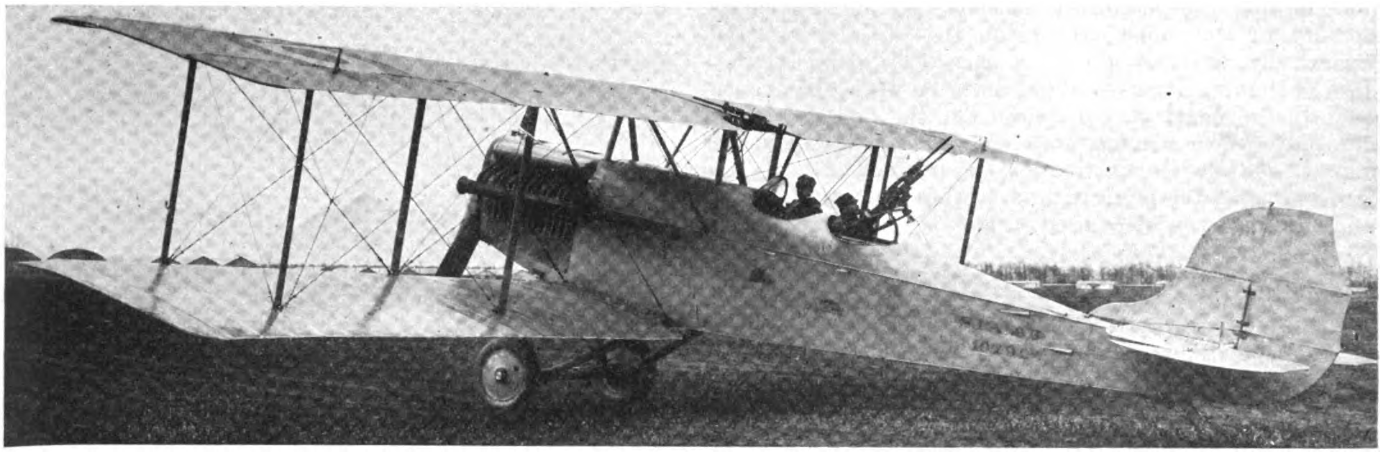


THE required 4-day notice of a probable Transatlantic flight was filed with the British Admiralty on Sunday by Captain Alcock, pilot of the Vickers-Vimy airplane at St. John's, N. F. This airplane was assembled on the starting grounds. A. W. Brown is the navigator. The plane is equipped with two standard 350-hp. Rolls-Royce engines and has a fuel capacity of 865 gal. and 50 gal. of lubricating oil. It is estimated to have a flight range of 2810 miles. The maximum speed is 100 m.p.h., but the speed for the long flight probably will be 90 m.p.h.

Fiat Plane for Transatlantic Flight

A High-Speed Machine with Single 700-Hp. Engine Designed to Make the 2000-Mile Trip in 14 Hours

By W. F. Bradley

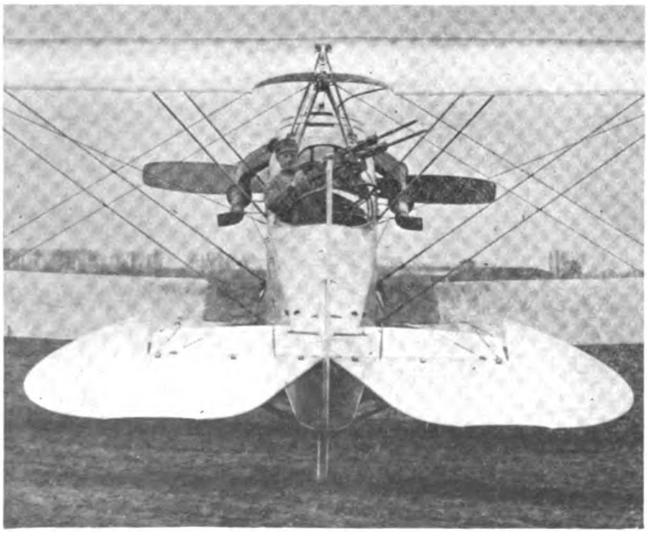


Fiat bombing and reconnoissance plane which is to make a transatlantic flight

TURIN, ITALY, May 15—Fiat is building a special airplane which will be capable of crossing the Atlantic in 14 hours, without the assistance of steamers along the line of flight, according to officials of the concern.

The Fiat machine is a biplane having an all-metal fuselage, divided into watertight compartments which will contain 660 gal. of gasoline, this being more than sufficient for the flight across the Atlantic. In case of an accident, which obliges the pilot to come down on the water, this fuselage can be emptied almost instantaneously and will then serve as a lighter capable of keeping the pilot and passengers afloat for a number of hours.

The machine is the work of Engineer Rosatelli, who believes that the only method of crossing the Atlantic is by means of a very fast, big, load-carrying airplane.



Rear view of the fuselage

As the route selected is 2000 miles in length, the Fiat machine will have to average 145 miles an hour. It is claimed that the plane will have a higher speed than this, for just before the war came to a close Fiat had produced what is officially known as the BR-biplane, which had attained a speed of 158 miles an hour with a net load of 1 ton. This speed is higher than that attained by any of the chaser planes used on the front when the war came to a close. The experience gained in the construction of the BR is being made use of in building the Atlantic machine.

As in the case of the BR, a single Fiat 12-cylinder, 700-hp. engine will be used. This is an engine which has been produced in quantities for a considerable time. It is claimed that the BR-biplane was capable of carrying a load of 1½ tons and maintaining its speed of 158 miles an hour. This machine was therefore able to drop ½ ton of explosives on any point within a radius of 300 miles. When the armistice came into effect, no bombing machine in the Allied service was capable of making a trip of this length, even if running without a load of bombs.

The pilot will be Brack-Papa, who has a number of important records to his credit, among them being the passenger-carrying height record of 23,050 ft. in 1 hr. 3 min. It is stated that the pilot and those assisting him in this undertaking have developed a scheme whereby position may be plotted while over the water and while flying at a speed of 150 miles an hour. This system has been given a practical test in several long-distance flights, notably in the 1000 miles non-stop trip from Turin to Naples and back, which was accomplished in 10 hr. 30 min.

THE Bergie National Spark Plug Co., Rockford, Ill., has brought out a special spark plug for tractor and stationary engines with stone insulator. The insulator is claimed to be practically unbreakable, heat-proof, oil-proof and compression-tight.

The Kessler Super-Charge Engine Developed for Automobile Purposes

Uses Four-Stroke Cycle With Ramming Charge of Excess Air—Crankcase Compression Employed

FOR several years engineers have realized that one method of increasing the mean effective pressure of engines would be by increasing the volumetric efficiency. Naturally, with this in mind, the first thought is the utilization of some outside pressure to ram an excess charge into the combustion chamber. This idea has been dormant up to the time of the war, when the necessity for securing high compression pressures at extreme altitudes brought it into prominence again.

One of the super-charge engines which received attention from the Government at that time is the product of the Kessler Motor Co. of Detroit. This engine, which has been in a state of gradual development for nearly a decade, was under test by the navy aircraft authorities and was just about to be manufactured when hostilities ceased. The engine was then developed for automobile work, and, largely owing to the impetus given to improved engine design by aviation engineers during the war, it is now receiving a great amount of consideration.

The Kessler super-charge engine operates on the ordinary four-stroke cycle. At the bottom of the intake stroke, however, the piston uncovers ports through which is forced a quantity of air, constituting the super-charge. Thus, when the piston starts to rise on the compression stroke the pressure is already above atmospheric, and it is not necessary for the crank to travel through 20 or more degrees before compression actually starts. With this added volume of air it is necessary that the ratio of the total volume to the volume of the compression chamber be considerably less in the Kessler engine than it is in the normal engine. This is readily explained by the diagram shown in Fig. 4. The figures show a normal engine with a compression ratio of 5 to 1, and the lower two diagrams show a compression ratio with a Kessler super-charge engine of 3 2/3 to 1. Both of these engines would have approximately the same initial compression of 100 lb. per sq. in. Thus, although the compression space is larger in the Kessler engine, the compression is the same, owing to the excess of air admitted.

Crankcase compression is relied upon to furnish the super charge of air. The quantity of air admitted is governed by some form of valve between the crankcase and the cylinder intake ports. The form of valve used in the latest engines is a rotary, connected with the throttle so as to automatically govern the amount of air admitted by throttle conditions. On the intake stroke the regular poppet intake valve is employed, but it closes at bottom center or very nearly at bottom center, so that there is no chance for the incoming air to blow back through the poppet intake. In fact, it is important, as will be seen, to close the intake valve early enough so that there is no disturbance of the incoming charge through the poppet valve.

The operation of the engine is readily understood from the foregoing explanation of the cycle. As the piston descends on the intake stroke it draws in what would be the normal amount of charge, and just before the bottom of the stroke the incoming charge of air from the crankcase has passed through the rotary valve. As soon as the piston uncovers the ports the pure air from the crankcase rushes in, sweeping across the head of the piston and filling the bottom of the displacement space with air. This is compressed along with the charge which came in through the poppet valve, at about the same compression as is used in the ordinary high-speed gasoline engine. Firing occurs in the usual manner and exhaust is taken care of through the usual form of poppet exhaust valve.

Referring again to Fig. 4, it is readily apparent where the gain in mean effective pressure comes in. At the bottom of Fig. 4 are shown two typical cards, one from a standard gasoline engine and the other from the Kessler. It will be seen that the expansion curve is slower to drop in the Kessler engine than it is in the standard type. Thus, the higher pressures are available through the working stroke, and particularly at points where the

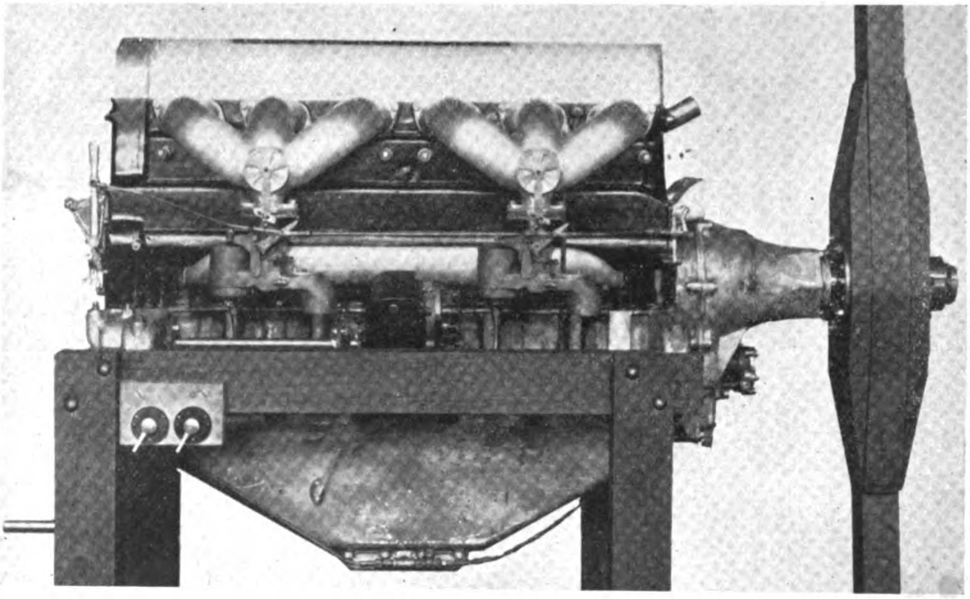


Fig. 2—Kessler aviation engine developed for the United States Navy, developing 200 hp. at 2400 r.p.m.

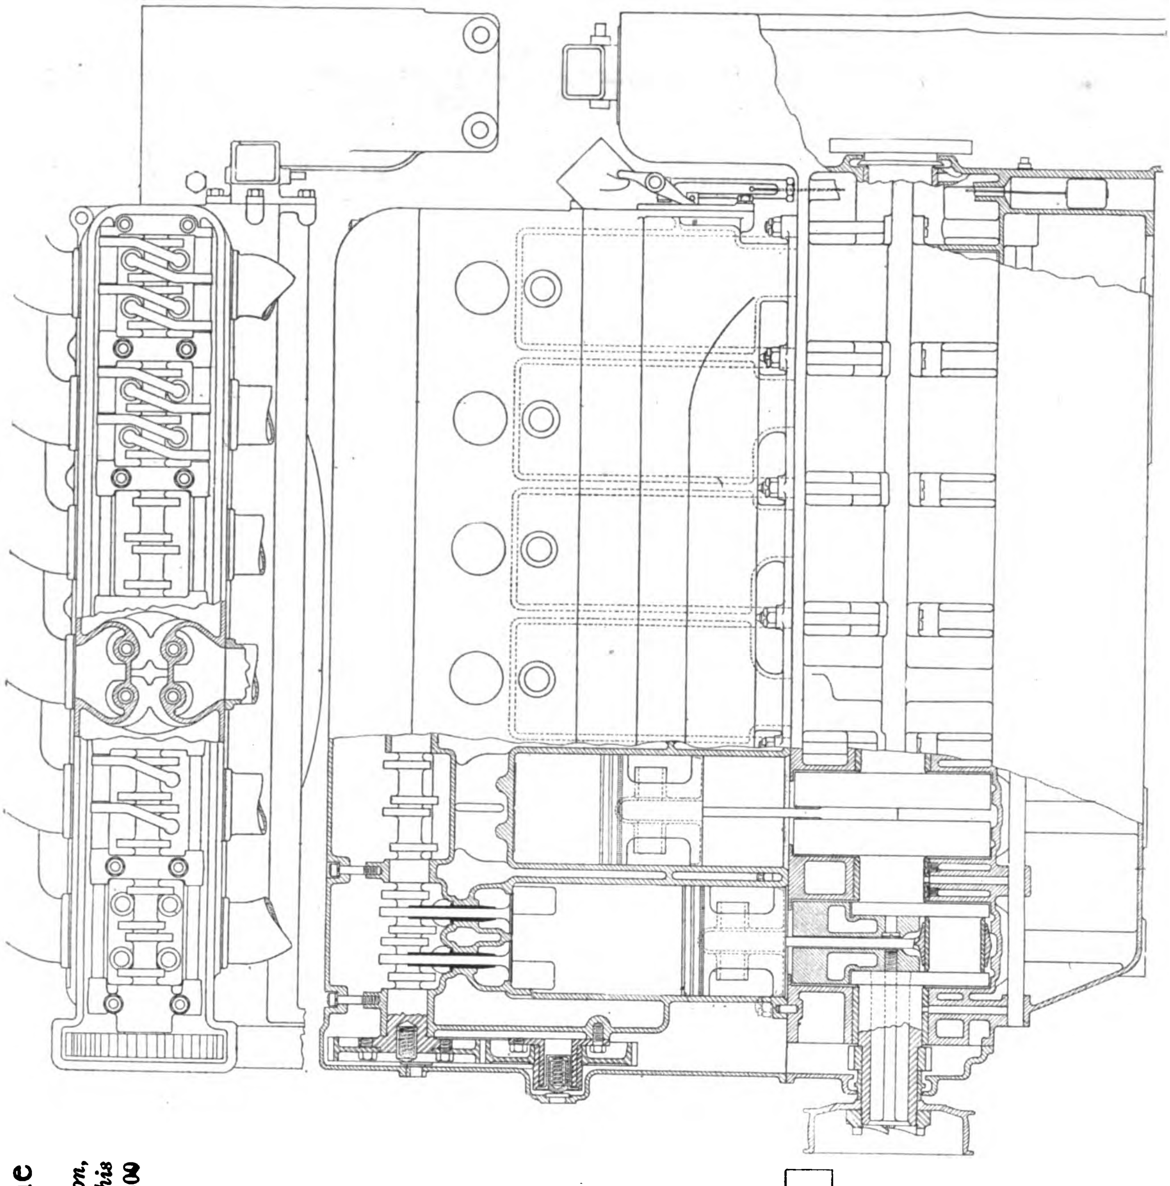

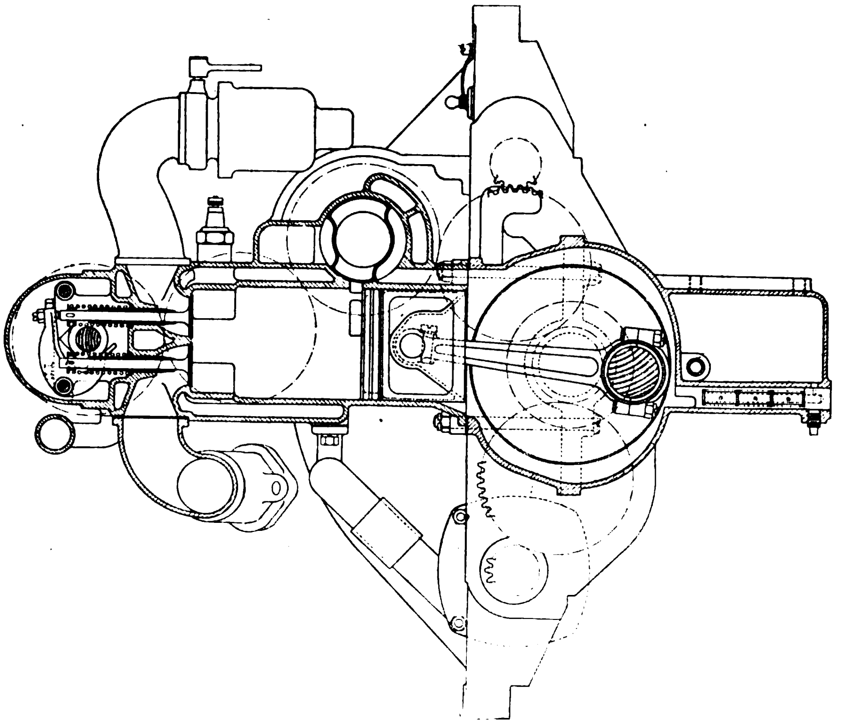

Fig. 1—Kessler Super-Charge Engine

Transverse section, longitudinal elevation partly in section, and top view of six-cylinder automobile type engine. This engine is of the overhead camshaft type and runs at 2600 r.p.m. The cylinder dimensions are 3¾ by 3¾ in.

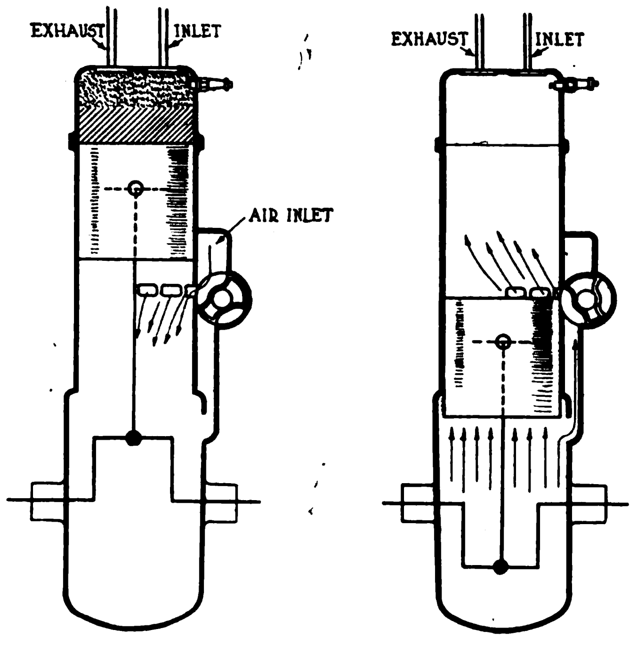

Fig. 3—Sketch showing cycle of Kessler super-charging engine and also stratification charge and cushioning effect under piston

maximum torque effort is being placed upon the cranks, due to their approach to the 90-deg. position.

In the upper part of Fig. 4 are illustrated three stages in the expansion of the charge in a typical gasoline engine with 5 to 1 compression ratio. The first expansion, to the point where the volume swept through by the piston is equal to the compression chamber volume, corresponds to a crank travel of 55 deg. After the second expansion, or when the volume swept through by the piston is equal to twice the combustion chamber volume, the crank has passed through 83 deg., and after the third expansion (three times compression chamber volume) it has passed through 113 deg. In the Kessler engine, owing to the greater volume of the compression chamber, the crank has passed through 70 deg. after the first expansion stage and 113 deg. after the second. Thus, with a greater volume of gas available on each working stroke, the expansion curve is bound to be higher throughout, and this accounts for the increased mean effective pressure.

Naturally, the first inquiry likely to be made regarding a cycle of this sort is whether or not the air dilution does not simply tend to thin out the mixture, but to this the inventors reply that they have evidence of marked stratification in the compression space; that this can be clearly shown by varying the location of the spark plugs. If the plugs are high, near the inlet stream from the poppet valves, perfect ignition results. On the other hand, if they are placed low where they would be in the path of the incoming air from the super-charging ports, either no ignition or very faulty ignition results, indicating that conditions of the charge are different in different parts of the cylinder. It is the claim of the Kessler company that this air drawn in through the ports at the bottom of the stroke lies on top of the piston and is carried up with it.

The explosion takes place in the upper part of the compression chamber and the air in the lower part absorbs heat from the explosion and then gives this heat up again during expansion. The resulting terminal pressure is somewhat higher than in the conventional engine, owing to the fact that it is not possible to get back all of the heat energy imparted to the excess air. A marked cushioning effect of the explosion is claimed, due to the presence of the excess air on top of the piston, which tends to retard the pressure peak. The cushioning effect is also claimed to reduce to a marked extent any tendency for a high compression engine to pound, as the blow on top of the piston is stated to be remarkably softened due to this volume of air.* A cushioning effect is also claimed for the crankcase compression, and it is said that at certain speeds the bearings automatically float, due to the relieving cushion of the air in the crankcase.

A staff representative of AUTOMOTIVE INDUSTRIES has

*This statement hardly agrees with the two indicator diagrams shown, of the standard and Kessler engines respectively, which show equal explosion pressures.—EDITOR.

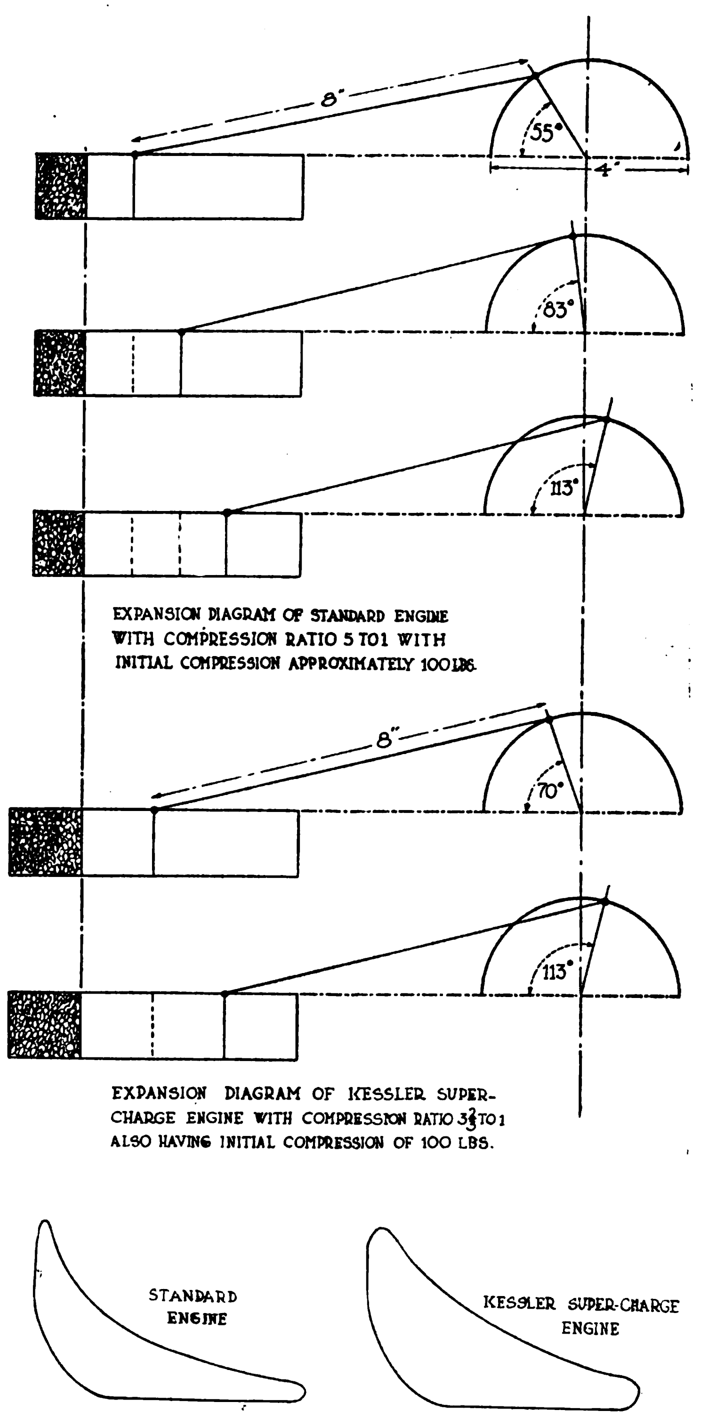

Fig. 4—Charts showing comparison of expansion diagrams of Kessler and standard engines

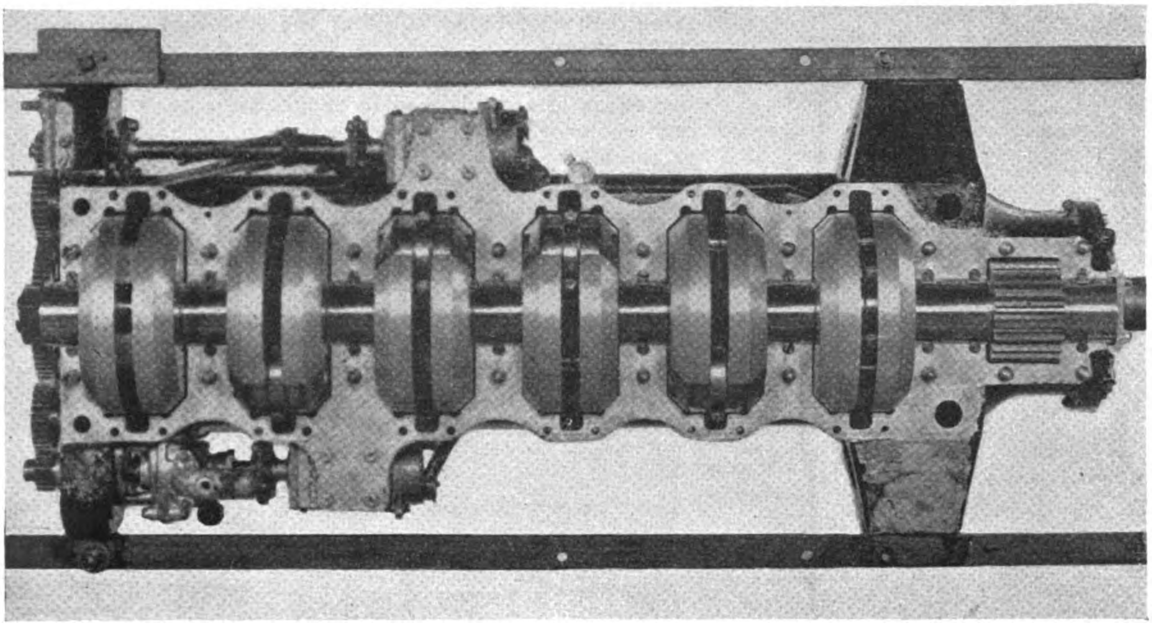

Fig. 5—Left—Counter-balanced crankshaft mounted in crankcase. Fig. 6—Right—Piston and connecting rod

seen at the Kessler plant a car with a four-cylinder Kessler engine mounted in it, this engine having made over 60,000 miles without having been taken down. The engine is in bad condition, and inasmuch as the supercharged air was drawn through an opening in the front end of the engine and the front of the engine itself is caked with the gritty accumulation of 5 years, it is safe to imagine that the inside of the engine is in extremely bad condition. The air intake for the super-charging air is controlled by a butterfly in this particular engine, and there is no screening or other device in front of it. Yet, in spite of this, the acceleration of the engine is remarkable, and, although the engine is a four, it compares favorably with multi-cylinder engines in this respect.

Claim Carbon Knocks Impossible

This engine is used by the Kessler company as evidence to support the claim that bearing loads are exceptionally light due to the balance secured by the air cushion in the crankcase and the air cushion above the piston at the time of explosion. The excess of air tends to act as a carbon cleaner also, so that carbon knocks are said to be impossible with this type of engine.

There are a great many structural designs possible with this cycle. It is nothing more than an ordinary type of engine plus the excess air charge admitted at the bottom of the suction stroke. It is quite apparent that the amount of air admitted must depend to some extent on the amount of charge drawn in, and consequently at reduced throttle openings the amount of air would be less than at full throttle opening. This is taken care of by the inter-connection of the valve controlling the air and the throttle. In the case of the rotary valve, the throttle does not control the opening and closing of the valve, but simply times it by means of a spiral guide, advancing or retarding the functions of the valve.

15-Pound Pressure Found Best

When idling only a very moderate amount of excess air is admitted, or none at all, but as soon as the load is increased the amount of air admitted is materially augmented, until at full open throttle the full period during which the ports are open is utilized in forcing in the air under a pressure of some 15 lb. This pressure has been experimented with and it has been found that best results are obtained with about that amount. A simple experiment with an ordinary engine will readily show what effect this has.

For instance, if a man were to blow into the petcock on top of the cylinder during the intake stroke or immediately after the intake were closed, and while the pressure was still at atmospheric in the cylinder, he would find an enormous increase in the final compression pressure. For this reason, with this amount of pressure put in the combustion chamber of the Kessler engine, it is possible to use a much greater volume of compression chamber and still have the same initial compression. Furthermore, as experiment with the old engine in the car has shown, slight leaks around the piston or past the valves do not reduce the power output to the same extent as in an ordinary engine.

The net result of this gain in mean effective pressure is the production of a much higher power output per

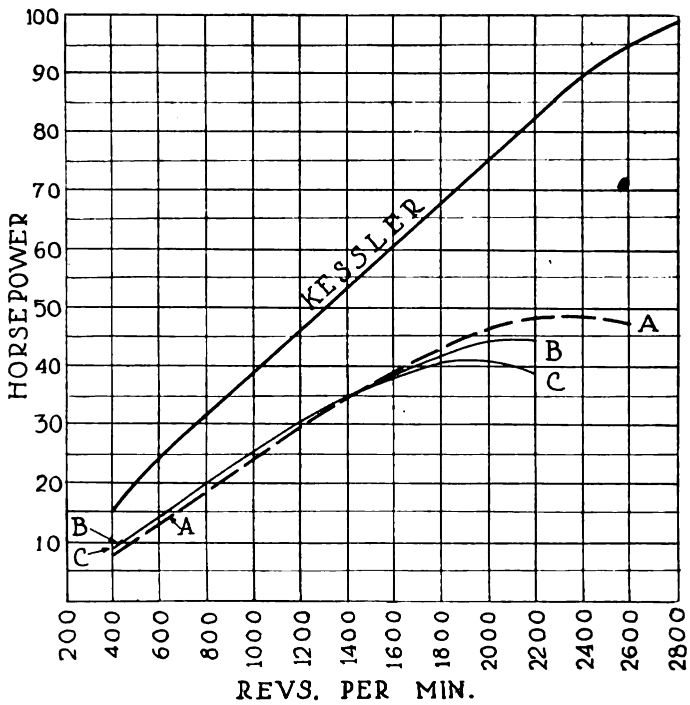

Fig. 7—Horsepower curves of Kessler and other standard engines, reduced to 247 cu. in. piston displacement

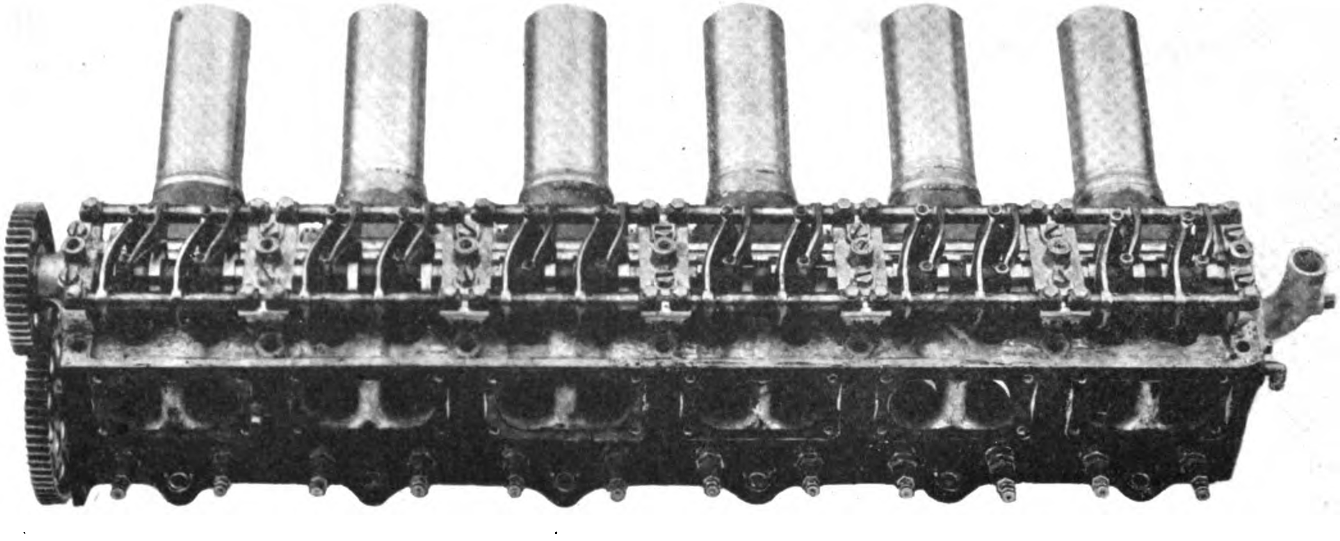

Fig. 8—Cylinder head assembly of Kessler super-charge engine for aviation purposes

unit of displacement. The curves given in Fig. 7 show three typical engines as compared with a Kessler engine, from a power output standpoint, according to claims made by the manufacturer. Curves A, B and C were made from test data of standard stock engines reduced to the basis of a 247 cu. in. piston displacement. Curve A was made by a $3\frac{1}{8}$ by 5-in., six-cylinder engine; B was made by a $3\frac{7}{8}$ by $4\frac{1}{2}$-in. four; and C, a $3\frac{1}{2}$ by $5\frac{1}{4}$-in. six. The curves all show marked drops at from 1600 r.p.m. up, the peak of the curve depending upon the valve timing.

The Kessler is a $3\frac{3}{4}$ by $3\frac{3}{4}$-in. six, with practically a straight line power curve between 800 and 2400 r.p.m. This curve is not a direct record of an actual engine run, but is based on test runs of similar engines, the data of which were compared and reduced to the displacement volume of a $3\frac{3}{4}$ by $3\frac{3}{4}$-in., six-cylinder engine with valve characteristics, etc., the same as in a sample Kessler engine just about to be constructed.

This curve indicates that by the use of a super charge the Kessler engine works in a much higher speed field than the ordinary types of engine and consequently would probably employ a much greater gear reduction than is utilized at the present time. As a matter of fact, the manufacturers believe that a ratio in the neighborhood of $5\frac{3}{4}$ to 1 or more would secure the greatest advantage from the engine. The claim of 100 hp. at 2900 r.p.m. from a $3\frac{3}{4}$ by $3\frac{3}{4}$-in. six appears radical at first sight, but the Kessler company states that in view of the results obtained in tests made on Government engines, this is considered a conservative estimate.

Engineers from motor car companies who have gone over the designs and have seen aviation engines built in accordance with this cycle have expressed their opinion that results of the kind denoted in the horsepower curve herewith are highly probable. One large concern has placed a provisional order for several thousand engines, provided certain output conditions less severe than this can be met by the engine.

From a design standpoint it is not necessary to depart very radically from ordinary practice in the construction of an engine. A very interesting piston has, however, been worked out by Kessler and is illustrated herewith. This piston is closed across the base, with a slot and webbed housing which encloses the top of the rod, thus giving a higher crankcase compression by eliminating the volume usually contained within the piston. The pistons are made either with a flat head or slightly domed. It has been found on aviation engines that were taken down and examined after long runs that this head is kept remarkably cool and free from carbon by the air blast from the super-charging air.

Furthermore, it is part of the theory of Kessler that the cushioning air lying on top of the piston also has the effect of preventing the extreme heat from reaching the head of the piston in the way that it does in the case of the ordinary type of engine at the point of maximum pressure, or at the peak of combustion.

As will be noted in the illustration herewith, Kessler

Ignition Work at the Bureau of Standards*

Effects of Various Types of Spark on Engine Power—Spark Plug Faults and Their Remedies—Standard Tests, Methods and Specifications of Spark Plugs—Effects of the Auxiliary Gap

By Francis B. Silsbee

I—INTRODUCTION

DURING the past two years the Bureau of Standards has been carrying on an extensive study of various problems connected with internal-combustion engines and their accessories. While the work was intended primarily to assist in the development of prime movers for aircraft, the results are, of course, almost equally applicable to gasoline engines used for any of the myriad other purposes—trucks, tractors, tanks, motor boats, etc.—to which they are applied.

The work was undertaken at the suggestion of the National Advisory Committee for Aeronautics, and has consisted in a large measure of specific tests of various devices submitted by the different military branches of the Government, together with a systematic investigation of the more fundamental problems. Active co-operation has been maintained with the Bureau of Aircraft Production and with the Navy Department on the one hand, and with the Society of Automotive Engineers and the various manufacturers interested, on the other.

The Bureau of Standards was thus enabled to act as a connecting link between the producers and the consumers, and, being unbiased by commercial relationships, it could give to both impartial testing and consulting service. The laboratory facilities permitted the carrying out of many delicate measurements not readily undertaken by industrial concerns, and much special apparatus was constructed for the purpose. On the other hand, the difficulties attendant upon factory production were fully recognized, and care was taken not to carry the development of details so far as to trespass upon the problems more properly handled by the manufacturer.

The experiments and methods of general interest have been described in detail in a series of Aeronautic Power Plant Reports issued by the Bureau, and will be printed in full in the Fourth Annual Report of the National Advisory Committee for Aeronautics. They will be referred to below by their numbers in both the A. P. P. series and the N. A. C. series.[1]

At the right are the electric furnaces and in the center the instruments used in measuring the electrical resistance of the insulator. At the rear are sample plugs and porcelain cups

**During the war this work was carried on with various special military funds which are no longer available. It is to be hoped that the work already accomplished, and the problems which lie in the future, are of sufficient value to the progress of the automotive industries to justify the new Congress in supplying funds to continue the work during the reconstruction period.*—EDITOR.

[1]A limited number of these reports is available for distribution by the Bureau of Standards and will be sent upon application to parties directly interested in the results. An additional supply of reprints of the N. A. C. A. Reports will be available later. The titles and numbers of these reports are as follows: [*See foot of next page.*]

The ignition work formed one branch of this general investigation, the other divisions being studies of carburetion, radiators, fuels, lubrication, and the effects of altitude upon engine performance. It is the purpose of this article to outline the various phases of the ignition work, to show their relations to each other and to the general question of engine performance, and to point out some of the outstanding problems which should be attacked in the immediate future.

The process of ignition in an internal combustion engine is essentially a trigger effect, i. e., a very small cause produces a very large effect which bears no direct relationship to the magnitude of the cause. Thus the energy delivered to the crankshaft of a Liberty engine by a single explosion is over 100,000 times the energy of the spark which initiated that explosion.

The problems met with in this work are therefore different from those usually occurring in engineering practice, and instead of studying the changes in one variable such an engine power which results from corresponding changes in another variable, such as mixture ratio or altitude, we are interested only in the effects of radical changes in the quality of the spark and particularly in the conditions which may determine the presence or absence of any spark at all.

The work therefore naturally divides itself into two parts, first, a study of the actual phenomena of the ignition of a combustible mixture by an electric spark, and, second, a study of the apparatus used to produce the spark and of the various troubles which are encountered in its operation.

II—IGNITION OF GASOLINE MIXTURES

Comparatively little work was done on the former of these problems, for two reasons. First, a complete study of the phenomena concerned would require a very long and elaborate research, and could not have been completed in time to yield results of any military value even if the war had lasted much longer than it did. Secondly, the bulk of the experimental evidence available, as well as preliminary experiments which were made at the Bureau, indicated that there was little likelihood of obtaining any marked increase in engine power by modifying the method of ignition.

Machine for testing spark plugs for resistance to mechanical shock

The experiments performed along this line consisted in measuring the power of an engine ignited by sparks of different quality. These types of spark were: (a) the usual magneto spark which has an initial current of about 0.070 ampere and lasts 0.002 second; (b) the same system with an auxiliary spark gap in series with the plug (this has the effect of decreasing the duration and energy content of the spark to about half the former value); and (c) the same system with a condenser connected in parallel with the spark plug. This has the effect of greatly increasing the initial value of the current but produces a highly damped oscillatory discharge of very high frequency lasting only a few hundred-thousandths of a second.

Precisely the same power was obtained from the engine with each type of spark. This result, together with similar data obtained elsewhere, indicates quite strongly that the slogan "A spark's a spark" is a fairly safe guide in ignition work. While this is apparently contradictory to the widely held belief in the peculiar efficacy of "fat" or "hot" sparks, it is highly probable that all cases of trouble from so-called "weak" sparks are really caused by the entire absence or wrong timing of the spark.

The presence of a spark external to the cylinder or even at a series gap is no certain indication that a spark is produced within the cylinder if the plug is in poor condition. There are, however, many interesting questions to be settled along this line, as, for example: Is a spark of large heat content and long duration beneficial in cases where the carburetion is poor and the fuel is in the form of drops or spray? What effect do various types of spark have on the velocity of flame propagation in the cylinder? Is there an appreciable time elapsing between the passage of the spark and the beginning of the spread of the flame? A method for the measurement of the velocity of flame propagation has been developed at the Bureau and will permit a direct attack on these problems.

III—STUDY OF APPARATUS

The second class of investigations, namely, the study of various types of ignition apparatus to determine the relative merits of those then available and to indicate the possibilities for improvement, showed much more prospect of yielding results of immediate value, and the bulk of the work during the war was directly or indirectly of this nature. Since the results mentioned above indicated that the engine performance did

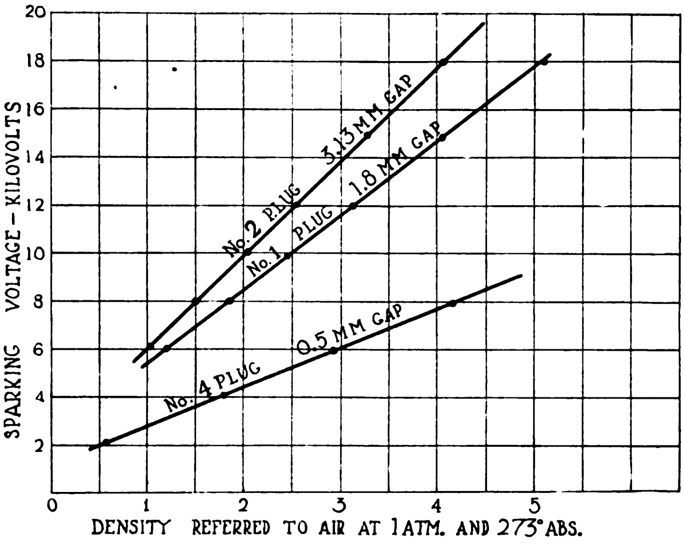

Fig. 1—Variation of spark plug voltage with length of and pressure at gap

not depend to any considerable extent upon the quality of spark produced, an estimate of the relative merits of and improvements in ignition apparatus should apparently be based primarily upon the reliability of the apparatus under service conditions and the ability of the system to function even if the conditions under which it is required to operate become unduly severe.

"The proof of the pudding is in the eating," and it is obvious that the reliability of a given make of spark plug, for instance, can ultimately be determined only from the compilation of accurate statistical data on the life and final cause of failure of several thousand such plugs in a given type of engine. The securing of such statistical data is in no sense a laboratory job and can be carried out most easily by the maker, either of the accessory in question or of the completed engine.

Even when a large number of engines are in constant use, as at a flying-field, it is no easy matter to obtain accurate statistics, and the absence of satisfactory data of this nature has been felt throughout the work, even up to the present time, as the most serious single limitation upon the progress of developmental work.

Laboratory experiments can, however, show the details of certain specific types of failure, can determine the properties of the materials concerned, and can thus indicate the magnitude of the factors of safety and lead to improvement in materials and design.

IV—CONDITIONS OF OPERATION

It became evident early in the work that more definite knowledge was needed of the conditions under which the spark plugs and ignition system were required to operate. Preliminary experiments were therefore made to measure the temperature at various points in a spark plug while operating in an aviation engine, and of the voltage which was required to pass a spark through the compressed and heated charge in the cylinder at the end of the compression stroke. These experiments are described in detail in A. P. P. Reports Nos. 12 and 14 (N. A. C. Reports Nos. 52 and 54).

The burning gases in the combustion space probably reach a temperature of 2500 deg. C., but the duration of this high temperature is so short and the frequency of repetition of the engine cycle is so rapid that the spark plug maintains a much lower and a practically steady average temperature. In the experiments the tip of the electrode was found to reach an average temperature of about 900 deg. C., while the porcelain up in the body of the shell was heated to 250 deg. C., and the metal of the shell was about 100 deg. C.

There remains much work to be done on the effect on spark plug temperatures of variations in the speed and mean effective pressure of the engine and also of the temperature distribution in plugs of various types. The rate of heat transfer from the hot gases to the material of the plug is still unknown and the degree to which the plug temperatures can be reduced by increasing the thermal conductivity of the insulator is consequently undetermined.

A study of the conditions of temperature, mixture ratio, turbulence, etc., under which the deposition of carbon on the insulator will occur and of the effect of various shielding devices on the rate of deposition is also of very immediate practical value, but is as yet a virgin field.

The voltage required to produce a spark in air at various pressures and temperatures was found to depend upon only the density of the air and to be nearly proportional to the density as shown in Fig. 1. From this plot and the known compression ratio of any engine, it is possible to estimate the increase in sparking voltage resulting from the compression. Measurements with a special crest voltmeter of the voltage actually applied to the plugs in a Hall-Scott engine while running at full power indicated a value of 6000 volts, which is in good agreement with the above data.

V—OUTLINE OF OPERATION OF IGNITION SYSTEM

A second essential preliminary to an investigation of the performance of ignition systems is to have a clear and definite understanding of the theory of their operation. The high-tension magneto and the induction coil are exceedingly complex electrical systems, and while the general principles of their operation are well known, there exists among both manufacturers and users much confusion of thought as to the precise functions of the various parts.

This condition is due in part to the fact that the industry originated with the German Bosch Co. and has grown in considerable measure, though with notable exceptions, by imitating their designs. Moreover, with the exception of several very excellent articles which have been published recently by Biffi[1] in Italy, Armagnat[2] in France, and Young[3] in England, and the highly mathematical papers of Jones[4] and of Campbell[5] there is

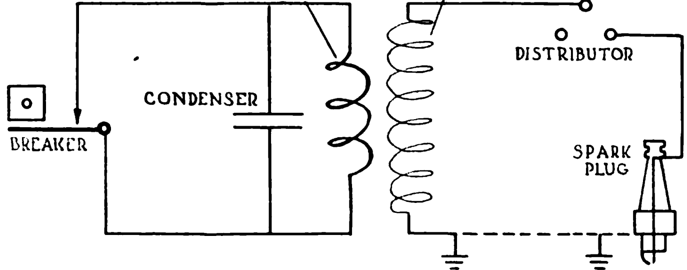

Fig. 2—Diagram of high tension ignition circuits

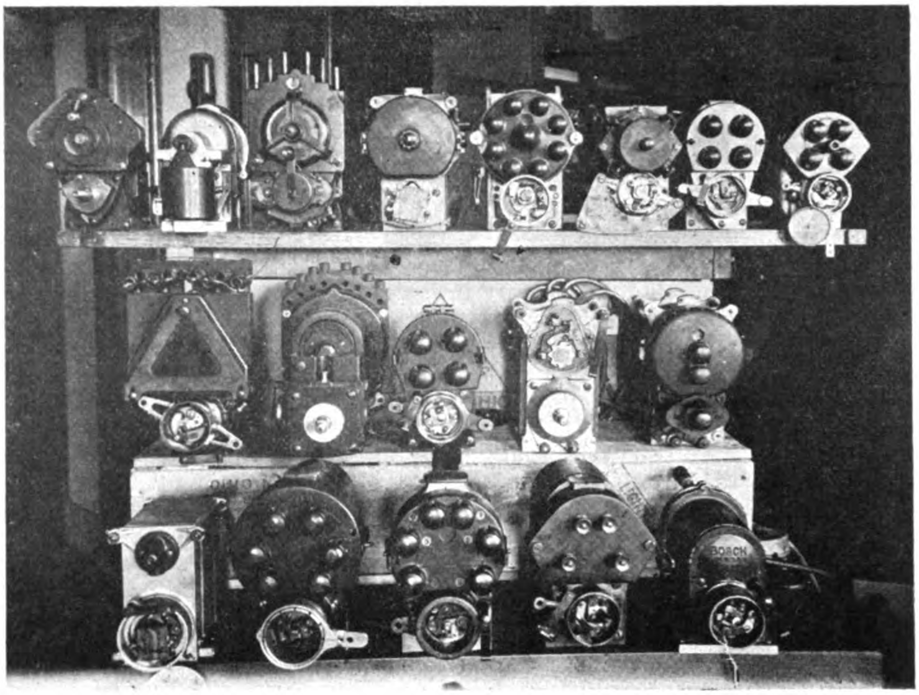
no published data dealing at all deeply with the subject. As an attempt to clarify the situation A. P. P. Report No. 20 (N. A. C. No. 58-I) was prepared which discusses in detail the cycle of operations of the jump-spark ignition system and gives data showing the order of magnitude of the various quantities involved.



Group of magnetos submitted for test

The usual type of ignition system as indicated in Fig. 2 consists essentially of an induction coil which comprises an iron core surrounded by a primary winding of a few turns (about 150) of coarse wire and a secondary winding of many turns (about 10,000) of fine wire. The secondary is connected through the distributor to the central electrode of the spark plug in the proper cylinder of the engine. The primary is supplied with a current (3 to 5 amperes) either from a storage battery or in the case of a magneto by induction from the relative motion of the core and a permanent magnet. When a spark is desired in the engine, the primary current is suddenly interrupted by the breaker and the resultant rapid decrease in the magnetic flux through the secondary winding generates in it a sufficient voltage to produce a spark at the terminals of the spark plug. There are two essential characteristics of any apparatus of this type which must be borne in mind in considering its behavior under adverse conditions:

First, with the secondary circuit open, and with no safety gap present, the voltage will build up to a certain maximum value (10,000 to 20,000 volts) which is determined principally by the inductance and capacity of the circuits, and no spark will be produced unless the breakdown voltage of the gap between the spark plug electrodes is less than this value. A safety gap may, of course, limit the voltage to some lower value.

Second, if the spark plug is shunted by a resistance, the maximum voltage obtained across its terminals is very considerably reduced, the reduction being greater the smaller the shunting resistance. With most of the ignition systems studied, the voltage reached was found to become less than 6000 volts required to produce a spark if the shunting resistance was much less than 100,000 ohms.

It may therefore be said that present practice divides the burden of supplying satisfactory ignition between the spark plugs on the one hand and the magneto or coil on the other at the limits just mentioned. The spark plug is thus called upon to perform three functions: First, to maintain a gap between its electrodes which shall have a breakdown voltage of approximately 6000 volts; second, to maintain an insulation resistance between its terminals of not less than 100,000 ohms; and, third, to be substantially gas-tight in order that the leakage of heated gas through the plug may not raise it to such a high temperature as to cause pre-ignition of the engine and destruction of the plug. Conversely, the magneto is required to deliver at the plug terminals at least 6000 volts, at the proper time in the cycle, even if the plug resistance is as low as 100,000 ohms.

In case of trouble with the plug, the magneto or coil is required to supply either a very high voltage in cases when the spark plug gap has become fouled with oil and consequently has a high breakdown strength, or else to supply an unusually large current in cases where the plug is fouled with carbon. In this latter case, the magneto must send such a current through the carbon deposit that the product of this current multiplied by the electrical resistance of the deposit is at least equal to the sparking voltage of the gap.

VI—EXPERIMENTAL WORK ON SPARK PLUGS

The possible ways in which a spark plug may fail to fulfill its requirements may be enumerated as follows:

1. Fouling with carbon deposit causing short circuit.
2. Fouling with oil causing open circuit.
3. Cracking or breaking of the insulator.
4. Pre-ignition.
5. Conduction through the insulator.
6. Electrical puncture of the insulator.
7. Minor troubles, such as warping and corrosion of electrodes, etc.

The relative importance of these troubles depends upon the type of engine, and the statistical data available is too meagre to admit of a very definite conclusion on this point. The experience in the engine testing work at the Bureau and performance data obtained from France indicate that the order in which they are listed above is approximately that of decreasing importance.

A general discussion of these various types of failure will be found in A. P. P. Report No. 22 (N. A. C. No. 51-I) in which the origin and identification of each type of failure is described and possible remedies for some of them are suggested.

It appeared early in the work that there were no generally recognized standard tests to determine the ability of a spark plug to resist these various types of failure, and the first work undertaken was the devising of such tests and the embodying of them in specifications for the use of the Bureau of Aircraft Production.

A large number of plugs of different types were tested in various ways and the results of the laboratory tests were correlated as well as possible with their service performance in aviation engines at the Bureau and elsewhere. The results are incorporated in specifications

Nos. 28004 and 28017 of the Air Service and the methods finally adopted are described in detail in A. P. P. Report No. 17 (N. A. C. No. 51-III).

The tests cover the electrical resistance of the insulating material while hot, its resistance to cracking from sudden temperature changes, its resistance to breaking from mechanical shock, and its dielectric strength while cold, and also the gas tightness of the assembled plug.

More detailed studies have been made of several of the specific types of failure listed above, which were particularly susceptible to laboratory investigation. The first of these was the conduction of electricity through the material of the insulator.

It had long been known that ceramic materials when heated lost their insulating properties and became to a certain extent conducting. In 1916 reports came to the attention of the Bureau that spark plug failures were setting a serious limit to the design of aircraft engines abroad, and that the trouble seemed to be due to the conducting properties of the insulators at the high temperatures encountered in the most modern engines. This trouble is frequently spoken of as "cutout."

Measurements were made of the electrical conductivity over a wide range of temperature of over 100 materials from different sources. This included spark plug insulators of porcelain, mica, glass, quartz, etc., as well as a number of porcelains prepared by the Ceramic Laboratory of the Bureau.

The method used in this work is described in A. P. P. Report No. 18 (N. A. C. No. 53-I), and the results in A. P. P. Report No. 19 (N. A. C. No. 53-II). By combining the data thus obtained with the measurements mentioned above of the temperatures in spark plugs while operating in an engine, one can estimate the resistance which a plug made of any of these materials would have in operation On making this comparison it appears that except for the poorest materials tested the resistance of the plug would be well on the safe side of the limiting value of 100,000 ohms.

Consequently this trouble can occur only with very poor materials, with very weak ignition systems, or with engines which are very much hotter than those experimented with at the Bureau. Later reports from abroad make no mention of this trouble, and its importance was apparently much exaggerated.

The testing of sample plugs submitted by the Bureau of Aircraft Production enabled the laboratory to accumulate data on the gas tightness of plugs of a variety of designs. This data has been analyzed and tabulated in A. P. P. Report No. 21 (N. A. C. No. 51-II).

It appears from this work that except in plugs where the insulator is moulded between the metal parts there is little connection between the design of the plug and its gas tightness, the latter depending much more on workmanship than on design. Observations at different pressures and temperatures show that the apertures through which the leakage occurs are in general opened up by high pressure and by heating. For this reason the routine tests are made while the plug is heated to 150 deg. C.

Two specific cases of electrode troubles were also investigated by the Bureau. In the first of these the electrodes in service broke off flush with the tip of the insulator. It was found that the cementing material became chemically active at the temperature of operation and attacked the metal electrode, rapidly eating it away. This trouble was remedied by substituting a different and inert filling material in the cement.

The second investigation was on the breaking of the side electrode in plugs where it was fastened at both ends. Microphotographs showed that prolonged heating of the nickel wire caused the formation of films of oxide in the cracks between the crystal grains of the metal. If the wire is subject to even a very slight tension, the cracks sink in deeply and the wire breaks in a short time.

If the tension is absent the cracks extend less rapidly and the life of the electrode is prolonged. It is probable that the well known slow corrosion of the electrodes by the spark is due to this effect, which causes the individual crystals to drop out of the wire as each becomes completely surrounded by its oxide film. These investigations are treated more fully in A. P. P. Reports No. 35 and No. 54 (N. A. C. No. 53-IV) respectively.

The most important part of the spark plug work was the development by the Ceramic Laboratory of the Bureau of a new porcelain body for use as a spark plug insulator. This work, which is described in A. P. P. Report No. 23 (N. A. C. No. 53-III), was begun while "cutout" was believed to be an important factor and the composition of the porcelain was chosen so as to give a high insulation resistance even at high temperatures. The various experimental porcelains mentioned above were made up with a view to determining the effect of various constituents upon the conductivity.

Measurements were also made of the thermal expansion over a wide range of temperature, and of resistance to sudden temperature changes, in the case of many of the bodies. By a careful balancing of the various components and the substitution of stable compounds like sillimanite ($Al_2O_3SiO_2$) in place of the free quartz, which tends to change its crystal form and dimensions at high temperatures, a porcelain-like body was finally obtained which could be prepared commercially and which was very definitely superior mechanically, thermally and electrically to any of the materials previously on the market. This composition has been made available to the public and is now being produced, with certain slight modifications, on a large scale by one of the largest spark plug manufacturers in the country.

VII—MAGNETO INVESTIGATIONS

The work on magnetos and induction coils has been much less complete than that on spark plugs, because of the much greater complexity of the subject and the less acute need for results. One of the early tests requested by the Signal Corps was the measurement of the energy output of a number of magnetos of different types.

The measurement of power electrically at the high voltages occurring in ignition systems is a rather difficult and delicate operation, but it is fortunately very simple to measure the same energy in the form of heat after it has been dissipated in the spark. Accordingly, as a preliminary to a more complete study of the subject a number of calorimetric measurements were made of the heat energy of the spark delivered at various speeds by the ignition system submitted.

The method used in this work is described in A. P. P. Report No. 15 (N. A. C. No. 56-I), and the results obtained are given in A. P. P. Report No. 13 (N. A. C. No. 56-II). The apparatus consists essentially of a hollow block of copper containing the spark gap. The rise of temperature of the copper which results from the passage of a known number of sparks is noted and compared with the rise produced by dissipating a known amount of energy in a heating coil, which is also enclosed in the block.

From this comparison the actual heat per spark can be computed in absolute measure. In considering these results it must be carefully borne in mind that the heat content of a spark is by no means a direct measure

of its igniting power and that it is only one of many items to be considered in judging the relative merits of different ignition systems.

Extensive oscillographic tests have been made on a number of magnetos to determine the instantaneous values of current, voltage, etc. during the operation of the machine. The wave forms obtained include the primary current on short circuit and the voltage on open circuit, together with the instants of opening and closing of the breaker. Also the primary and secondary currents and the primary voltage while operating normally have been recorded.

The oscillograph vibrator is not quick enough to indicate accurately the exceedingly rapid building up of voltage just after the primary "break," but the other features of the operation are brought out very clearly in the photographs.

Owing to the expense of reproducing the photographic records, copies of these oscillograms, which constitute A. P. P. Report No. 28, are being sent only to the manufacturers of the particular machines tested and to a few officials of the War Department. The results of measurements of the films are, however, being incorporated in other reports such as A. P. P. Report No. 20 (N. A. C. No. 58-I) dealing with various phases of the subject.

In interpreting the oscillograms, it was found desirable to know the ratio of secondary to primary turns in the particular coils tested and the combination of circuits described in A. P. P. Report No. 16 (N. A. C. No. 58-II) was devised to measure this ratio.

A considerable amount of work has also been done to develop methods for measuring the intrinsic constants of ignition apparatus, such as the electrostatic capacity of the secondary winding and the eddy currents in the core. It is hoped that the combination of quantitative data on these effects with a fairly simple mathematical theory of the electrical oscillations involved will enable the design of ignition apparatus to be put on a more scientific basis.

A comparison of the present empirical practice in this industry with the high degree of refinement attained in other branches of electrical engineering, as for example the design of power transformers in which the performance can be determined to a fraction of 1 per cent, indicates a wide field for advancement.

The various phases of this subject are so closely interlocked that the entire field must be worked out as a unit and consequently no partial reports have as yet been issued covering this part of the work.

The insulated cables used to connect the spark plugs with the distributor occasionally give trouble after considerable service by cracking of the insulation. This trouble usually occurs where the cable has been bent at a sharp angle.

At the request of the Bureau of Aircraft Production, this effect was investigated and the results were reported in A. P. P. Report No. 36. It was found to be due to a chemical attack on the rubber by ozone, which is in turn produced by the silent electrical discharge which occurs at the surface of the cable.

This chemical action is normally uniformly distributed and very slow, but, if the rubber is under tension as at the outside of a bend, the layer of oxide is pulled apart, continually exposing a fresh surface. This causes the cracks to sink rapidly into the material, until the insulating wall becomes so thin that it is punctured by the igniting voltage. The remedies for this trouble are the use of rubber compounds which are least susceptible to oxidation, the use of an impregnated air-tight braid and the avoidance of sharp bends in the wiring.

The problem of satisfying the requirements of ignition systems may be attacked, not only by the direct method of using an efficient and powerful source of energy, but also by the use of certain auxiliary devices which tend to produce the desired qualities of high voltage or large current.

The simplest of these for firing short circuited plugs is an auxiliary spark gap connected in series with the spark plug but external to the cylinder so that it will maintain a perfect insulation and definite breakdown voltage. Such a gap prevents the leakage of current across a fouled spark plug and permits the secondary voltage of the coil to build up in a normal manner. When this voltage becomes equal to the sparking voltage of the auxiliary gap, the gap breaks down and this full voltage is suddenly impressed on the spark plug, producing a spark at its gap also.

It has been found possible with this device to produce regular firing in an engine with a plug shunted by a resistance as low as 5,000 ohms, which is a very material reduction of the limit of 100,000 ohms specified above. Unfortunately, manufacturers of this type of device have brought it into unmerited disfavor by making impossibly extravagant claims for it in their advertising. A. P. P. Report No. 31 (N. A. C. No. 57) contains a discussion of the theory of this type of circuit and the results of trials of it in the laboratory and on engines.

The Lodge high frequency system is closely analogous to this series gap circuit, although the auxiliary gap is in parallel with the coil rather than in series, but is equally effective in firing a heavily shunted plug. The Dean high frequency system on the other hand is intended to supply a high voltage to overcome trouble from coating of the plug terminals with oil. The use of high frequencies permits the generation of very high voltages with a moderate number of turns, and it seems probable that further developments in ignition apparatus may be expected along this line.

VIII—SUMMARY

The foregoing outline of the ignition work at the Bureau of Standards has indicated the scope and purpose of the work. It has included a brief study of the effects of various types of spark discharge upon the power developed by a gasoline engine, and has indicated the conditions of temperature and voltage at which a spark plug is required to operate.

The cycle of operations of the jump spark ignition system has been discussed in some detail, and typical values of the various quantities of importance are stated. Standard methods of tests and specifications have been developed for spark plugs and a new porcelain body has been developed which is superior to those previously available for use in spark plug insulators.

Certain specific troubles, such as cracking and corrosion of electrodes, have been studied. Calorimetric measurements have been made of the power delivered by various typs of magnetos and extensive oscillographic tests have shown in detail various phases of operation.

A peculiar type of failure of the insulated cables connecting the spark plugs to the distributors has been studied, and tests have been made of the feasibility of the use of series spark gaps in firing fouled plugs.

It appears that from the above discussion the usefulness of the laboratory lies principally in studying specific difficulties, which experience has shown to be serious, in testing the properties of materials, in developing satisfactory standard methods of measurement, and in advancing the more theoretical side of the subject by fundamental research.

Specifications of Stock Engines fo[r]

In the following table are given the specifications of 96 models of automobile, truck and tractor engines now on the American market, the product of 34 different makers. The piston displacement ranges from 86.6 cu. in., which is only little beyond the motorcycle size, to 1344 cu. in., which is about the limit of size used for heavy tractors. This table should prove handy to manufacturers and engineers in search of an engine of a given output and certain characteristics.

The table also is instructive as regards trends in design. In view of the fact that some people have been inclined to regard the 4-cylinder engine as obsolete, on account of its limited use in passenger car models, the very strong representation of the four-cylinder type in the table is certainly interesting. Of the 96 engines listed 77 are of the four-cylinder type, while the remaining 19 are divided between 2, 6, 8 and 12-cylinder types.

It will be noticed that block casting of cylinders is becoming a very common practice, except for the largest bores. Although the practice of making cylinder heads detachable is rapidly gaining ground, there is still a goodly number of engines with integral heads. Some of the engines listed have been on the market for a number of years, and a change from integral to detachable head not only involves a complete redesign of the cylinder block but the making of complete new patterns and core boxes and extensive changes in manufacturing equipment.

The L-head type of cylinder predominates, but the valve-in-head construction is well represented and is preferred by many designers of kerosene-burning tractor engines. Mushroom cam followers are much more numerous than roller type cam followers, the two types being represented in about the proportion of 2:1.

The table shows that although there are more engines in which the cylinder axis intersects the crankshaft axis, the practice of offsetting the cylinders is pretty well established. In this connection it must be remembered that off-setting is of greatest advantage in a low-speed engine and a rather large proportion of the engines covered by the table is of this type.

As regards intake manifolds, the majority of them are separate from the cylinder block and head casting, but the integral manifold is not greatly in the minority.

Most engines are designed for pump circulation of the cooling water and a centrifugal pump for the purpose comes with the engine.

Explanation of abbreviations: Numbers in brackets indicate the column to which reference is made.

(1) **C** = Car; **T** = Truck; **Tr** = Tractor.
(5) **B** = Block; **P** = Pairs; **S** = Singly.
(7) **H** = Head; **R** = Right; **L** = Left; **Op** = Opposite; **Sl** = Sleeve.
(10) **R** = Roller; **M** = Mushroom.
(29) **I** = Integral; **S** = Separate.
(30) **C-P** = Centrifugal Pump; **Th** = Thermo-Syphon; **G-P** = Gear Pump; **Opt** = Optional.
N-C = Non-Circulating Splash.
(31) **S-P** = Splash-Pressure; **C-S** = Circulating-Splash; **Pr** = Pressure.
(32-35) **A** = Aluminum; **I** = Iron; **S-S** = Semi-Steel; **P-S** = Pressed Steel.

Passenger Cars, Trucks and Tractors

Pressure lubrication has greatly increased in popularity of late years, mainly in connection with the use of engines for tractor work and similar heavy duty. Non-circulating systems, which some people consider essential with kerosene-burning tractor engines, are still very rarely found on engines of this type.

A certain number of engine cylinders are cast of semi-steel, which, as is generally known, consists of gray iron to which a certain amount of steel scrap has been added. This addition of steel no doubt will change the physical properties of the metal in certain ways, notably by rendering it tougher, but it is a question in the mind of many engineers whether it will increase the resistance of the metal to abrasion; in other words, whether it will increase the life of a cylinder used as cylinders are used in tractor service.

It is noteworthy that no aluminum pistons are used in stock engines. Wherever the material of the cylinders is semi-steel, that of the pistons is the same.

Governors are fitted to practically all engines used in tractor work, but some manufacturers of these engines leave it optional with the purchaser what type of governor he should use.

More than half of all the engines are adapted for 3-point support, and the great majority are of the unit powerplant type.

With very few exceptions, the manufacturers of engines were quite frank about the weights of their machines, and this tabulation for the first time affords the opportunity of deriving the average weight of engine per N. A. C. C. horsepower, or per cubic inch piston displacement. There would be absolutely no use in taking averages for all of the engines, as the relative weights of passenger-car and tractor engines are quite different.

Chain drives for the camshaft and accessories drive shaft are not numerous. Their advantage being greater silence, and this having to be purchased at the price of greater manufacturing cost, one would expect to see the chain only on engines designed for passenger-car use. As regards designs of bell housing, it is interesting to note that while the S. A. E. standard housings are not universal, they are the next thing to it.

It will be noticed that the term "optional" occurs rather frequently in the table. This shows that the engine builders are willing to meet the desires of assemblers where this can be done without too much trouble.

Is Cylinder Offset?	If Offset—How Much?	Intake Manifold (Separate or Integral)	Water Circulated by	Lubrication System	Material of Crankcase	Material of Lower Half of Crankcase	Material of Cylinders	Material of Pistons	R.P.M. at which Maximum H.P. is Developed	R.P.M. at which Maximum Torque is Developed	Is Governor Fitted?	If so, what Type?	Governed Speed	Maximum Brake H.P. of Average Product	Weight of Engine Without Ignition or Carbureter (Lb.)	Overall Width of Engine (In.)	Overall Height of Engine (In.)	Overall Length of Engine (In.)	Type of Front End Drive	If Chain, what Type?	Adjustable or Non-adjustable	Points of Engine Support	Adapted for Heavy Fuel	Is Bell Housing Provided?	If so, what No. or Type?	MAKE AND MODEL OF ENGINE

Explanation of abbreviations: Numbers in brackets indicate the column to which reference is made.

(1) C = Car; T = Truck; Tr = Tractor.
(5) B = Block; P = Pairs; S = Singly.
(7) H = Head; R = Right; L = Left; Op = Opposite; Sl = Sleeve.
(10) R = Roller; M = Mushroom.
(29) I = Integral; S = Separate.
(30) C-P = Centrifugal Pump; Th = Thermo-Syphon; G-P = Gear Pump; Opt = Optional.
(31) S-P = Splash-Pressure; C-S = Circulating-Splash; Pr = Pressure; N-C = Non-Circulating Splash.
(32-35) A = Aluminum; I = Iron; S-S = Semi-Steel; P-S = Pressed Steel.

ger Cars, Trucks and Tractors (Continued)

Is Cylinder Offset?	If Offset—How Much?	Intake Manifold (Separate or Integral)	Water Circulated by	Lubrication System	Material of Crankcase	Material of Lower Half of Crankcase	Material of Cylinders	Material of Pistons	R.P.M. at which Maximum H.P. is Developed	R.P.M. at which Maximum Torque is Developed	Is Governor Fitted?	If so, what Type?	Governed Speed	Maximum Brake H.P. of Average Product	Weight of Engine Without Ignition or Carbureter (Lb.)	Overall Width of Engine (In.)	Overall Height of Engine (In.)	Overall Length of Engine (In.)	Type of Front End Drive	If Chain, what Type?	Adjustable or Non-adjustable	Points of Engine Support	Adapted for Heavy Fuel	Is Bell Housing Provided?	If so, what No. or Type?	MAKE AND MODEL OF ENGINE

Two-Stroke Engines for Motorcycles*

An Outline of Their Advantages and Disadvantages and a Description of a Design Due to the Author

By E. Tilston

UP to the present time the two-stroke type of engine has been used only for lightweight motorcycles and small motor boats—except in the case of engines of the Diesel and hot-bulb types. The present type of three-port two-stroke engine gives about one-third more power than the four-stroke engine for the same size of cylinder with the engine revolving at normal speeds, although the power curve falls away more rapidly than with the four-stroke engine at abnormal speeds.

Seeing that the two-stroke engine gives more power than the four-stroke, the former can be made smaller for the same horsepower, and consequently the piston is reduced in size, and the connecting rod made shorter on account of the difference in length of stroke. With two cylinders the superiority of the two-stroke engine is more pronounced in torque, balance and absence of vibration. No one has yet been foolish enough to adopt a twin-cylinder vertical four-stroke engine for motorcycles (although its torque is far superior to the Vee type), for the reason that the balance is inferior. The only two-cylinder four-stroke engine with good torque and balance is the horizontal twin-cylinder, but even this cannot be placed alongside the two-cylinder two-stroke engine with the power stroke taking place simultaneously at the two opposite ends, which not only balances the thrust on the bearings, but considerably reduces wear and tear. Although the horizontal twin-cylinder type is admirable in balance and torque in both engines, the author does not consider either a good proposition in a motorcycle on account of frame design.

This question of torque, balance and vibration brought about the demise of the one- and two-cylinder vertical four-stroke engine in motor cars, and the author is of the opinion that history will repeat itself in the motorcycle. If it is necessary to adopt an engine in a motor car which gives a propelling force every stroke, how much more necessary is it in the motorcycle where there is so little room for springing to minimize vibration? With regard to torque, the two-cylinder vertical two-stroke engine is in every way equal to the four-cylinder four-stroke engine, although the balance may not be so good, but as one piston is descending while the other is ascending, what little difference there is in balance through the couple is offset by halving the number of cylinders and reducing the reciprocating parts.

Simplicity and Lower Cost Excellent Advantages

The greater simplicity and lower cost of the two-stroke engine are excellent advantages from a production point of view. Providing that carburetion is the same in both types of engine, the double-firing stroke will give the best result in starting, especially if this is coupled with half the weight of reciprocating parts.

Much attention has been given of late to improving the carburetion in connection with the four-stroke engine by exhaust jacketing the inlet pipe. This is obtained in the two-stroke engine without any inaccessible pipes, as the charge entering the crankcase is heated, which has a further tendency to keep the engine cool.

Accessibility—another point in which the two-stroke engine excels—not only adds to the cleanliness of the machine, but also to its appearance, which is a desirable feature when selling. If accompanied by simplicity it is a great inducement to the novice who is about to purchase a motorcycle, and there can be no doubt that it is a very big factor in increasing the army of motorcyclists.

*From a paper presented to the Institution of Automobile Engineers, London.

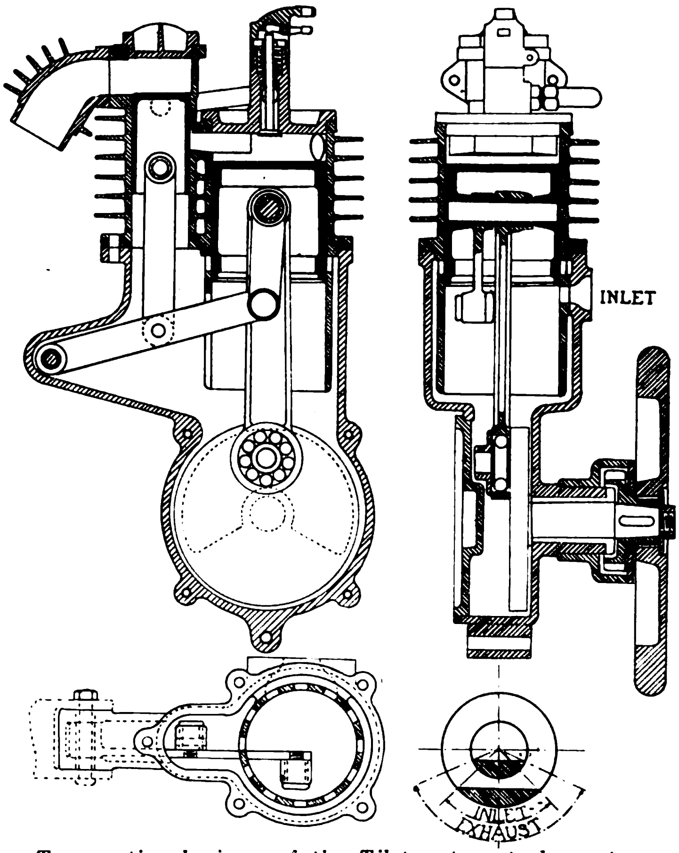
It is only necessary to consider the simplicity of the two-stroke engine with its absence of valves, and then to turn to the timing case of the four-stroke engine, which needs constant adjustment, to realize what scope a designer has in making the two-stroke engine accessible.

Best Type of Engine for Frame Design

The two-stroke engine appears to be the best type for frame design, inasmuch as character of torque and balance (which minimize vibration), total weight, and weight of reciprocating parts are in its favor.

Just as one- and two-cylinder engines in motor cars were discarded on account of inferior torque, so there will be a tendency towards multiple cylinders in motorcycle design. It appears impossible to make a two-cylinder four-stroke engine of even torque and good balance unless the cylinders are placed at 180 deg. The horizontal twin-cylinder arrangement in either type of engine—as previously mentioned—does not lend itself to frame design, while there are other disadvantages in cooling, if the engine is placed with the flywheel revolving in the direction of the road wheels.

Frame design is a most important matter, and the public —especially those who are familiar with frame breakages during the war—will look with suspicion in future on the machine that lets them down. The author admits that bad springing is responsible for a good many frame breakages, but there is also the question of best type of engine in designing a good frame without adding unnecessary length.



Two sectional views of the Tilston two-stroke motorcycle engine, with piston type exhaust valve

In regard to weight the advantage lies with the two-stroke engine. A saving in weight is a saving in cost, and is of enormous benefit in case of an accident which necessitates the machine being pushed home. There is also a considerable saving in the wear and tear on tires.

Reliability

There can be no doubt that the present-day two-stroke engine is very unreliable for large horsepowers. In the first instance it is necessary to bear in mind that there are two power impulses against one in the four-stroke engine, consequently the moving parts, especially the piston and small end of the connecting rod, are more likely to get overheated. This is counterbalanced to a certain extent by the fact that a new cool carbureted charge is drawn into the crankcase every revolution, which lies inside the piston, and tends to keep these parts cool. In the present-day two-stroke engine there are other reasons for overheating, namely, the exhaust port is arranged at the lower end of the cylinder, and the hot burnt gases do not tend to escape, consequently the piston in ascending is subject to the heat from the exhaust. It must be admitted that even in small two-stroke engines of 250 c.c. it frequently happens that the engine peters out on a fast run of 50 miles or so. For further proof of the evil effect of exhausting at the lower end of the cylinder, it is only necessary to examine the top piston rings on the exhaust side of any two-stroke engine, and they will be found caked up with carbon, and often require cutting out after a few hundred miles' run. To sum up, the disadvantages of exhausting at the lower end of the cylinder are as follows:

Loss of incoming charge through the exhaust, imperfect scavenging, overheating of the piston, which is increased by the deflector, and caking of piston rings with carbon on the exhaust side, all of which add considerably to unreliability and waste.

Economy

The small difference in economy of fuel between the present-day two-stroke engine and the four-stroke engine is no doubt due to the loss of incoming charge through the exhaust, combined with the large amount of burnt gases in the cylinder. Remove these two evils, and there is no reason why the two-stroke engine should not equal the four-stroke engine as regards economy.

It would naturally be imagined that the two-stroke engine would be more flexible than the four-stroke engine, seeing that a single-cylinder two-stroke engine is equal in power impulses to a two-cylinder four-stroke engine, and there can be no question but that by increasing the number of cylinders flexibility is improved. In the author's opinion, the reason why the two-stroke engine is actually not more flexible than the four-stroke engine is that there is a greater amount of exhaust gas left in the cylinder on the compression stroke than is found in the four-stroke engine. If all the exhaust gases can be ejected from the cylinder, at every position of throttle opening, the flexibility would increase in proportion to its superior torque.

In the two-stroke engine there are no valves, which are generally the source of heating troubles in the four-stroke engine. If the cylinder is scavenged from end to end, and the exhaust removed to the top end of the cylinder, with a flat-topped piston, the author is of opinion that the two-stroke engine will give less trouble in overheating than the four-stroke engine, provided that the means for controlling the exhaust are as efficient from a cooling point of view as the other parts of the engine.

Desirable and Undesirable Features

Undesirable

The deflector on the top of the piston.

The exhaust at the lower end of the cylinder.

Valves—they must not give trouble through overheating.

The waste of the incoming charge through the exhaust.

Desirable

The cylinder scavenged from end to end through a ring of ports and an annulus.

A light flat-topped piston.

The incoming charge must fill the cylinder completely with the throttle full open.

No exhaust left in the cylinder at any position of the throttle.

Both inlet and outlet must be unobstructed to allow free passage, otherwise back pressure of the outgoing exhaust prevents the new charge entering, and diffusion of the two results in escape of the new charge through the exhaust. If these ideals are accomplished, it is possible to more than double the power as compared with the four-stroke engine for the same c.c.

The combustion space represents roughly 20 per cent of the cylinder volume, and if this could be filled with a new charge and fired twice, as compared with the combustion space in the four-stroke engine, which is filled with burnt gases and fired once, then the possibility of increasing the power of the two-stroke engine may be more than doubled.

The two-stroke engine that the author is responsible for is the result of very careful consideration of the merits and demerits of both types of engines on the lines laid down.

When the first experimental engine was demonstrated at Stonebridge several criticized it on account of its cost and extra moving parts as compared with the ordinary two-stroke engine. However, it is impossible to control an exhaust port at the top end of the cylinder and provide an extra pump for displacement without additional moving parts and expense. It will be noticed that the means to control the exhaust port (the piston valve) also gives additional displacement to induce sufficient charge into the crankcase from the carbureter, which the movement of the piston alone fails to accomplish.

The lower end of the piston and piston valve are both open to the crankcase and, as they move upwardly together, their combined displacement is available to fill the cylinder at the end of the next downward stroke of the piston. On the explosion stroke, the closing of the port from the carbureter to the crankcase first occurs, followed by compression of the charge in the crankcase. The opening of the exhaust at the top end of the cylinder follows, and shortly afterward the inlet ports from the crankcase to the cylinder are opened by the main piston.

An exhaust poppet valve overheats, but with a piston valve as shown this type of engine does not get nearly so hot as the three-port two-stroke engine without valves.

When the explosion takes place the piston valve is at the top of its stroke and is considerably above the combustion space. The cool carbureted charge, introduced into the crankcase every revolution, lies not only inside and around the main piston, but also inside the piston valve, and as there is only a thin wall of metal separating the hot explosion from the newly introduced cool charge, the excessive heat from the former is absorbed by the charge, which is afterward passed into the cylinder, thus cooling the piston valve and preventing dissipation of heat from the outside. This helps the fuel consumption and aids in an easy start.

There are no rings on the piston valve, which is of the same metal as the cylinder. A clearance of 0.001 in. is allowed between the bore and the valve, and the short stroke of the valve, in conjunction with the cooling effect of the charge lying inside, allows the temperature from end to end of the valve to be maintained practically constant, thereby permitting free movement without fear of seizing.

The top rings of the main piston maintain their elasticity under severe loads and constant running because the piston is cooled internally every revolution. The piston valve is operated by link motion from the piston pin, with about half the stroke of the main piston. There are several ways in which the piston valve can be reciprocated, but the design shown allows the crankcase volume to be cut down with a view to increasing the compression.

It will be noticed that the compression release valve in the cylinder head is so arranged that the passage from the cylinder is in communication with the upper end of the piston valve cylinder. Just before the explosion occurs, the piston valve has moved up and prevented an explosion occurring in the exhaust pipe and muffler, and a very simple and effective method of lowering the compression is obtained, which facilitates easy starting.

The Economics of Flight

Effect of Altitude of Flight on the Energy Expenditure Necessary to Cover a Given Distance—Problem Involves a Consideration of Many Factors

By H. B. Irving

DURING the war the economics of flying was of no importance as far as fighting in the air was concerned. It had to be considered seriously in connection with long-distance air raids, when it was of great importance to cover the longest possible distance on the minimum of gasoline, and for reconnaissance also the economics of flying deserved attention.

But with the end of the war this subject appears in a quite different light. Now the question of cost of transport enters in largely, whereas, during the war the question of cost was scarcely considered. The problem in commercial aviation is to transport goods or passengers at the cheapest rate at which it is possible to run a service which will offer sufficient advantages over existing services to be able to compete with or replace them.

It is the object of the present article to give a brief consideration of the aerodynamic principles which govern the economics of flying without entering into the multitude of other considerations which affect the question. The aerodynamic principles are perfectly general, while the other considerations are usually of a particular nature and need special application to each case.

Aerodynamically the economics of flight is concerned with the effect of the various conditions of flight on the energy required to carry a given weight a given distance. Take first of all the case of a given body whose resistance is $P\rho V^2$, where K is a constant, ρ is the density of the air, and V is the speed through the air. The fact that K is constant of course implies that the resistance of the given body varies as the density of the air and as the square of the speed. The former assumption is always true, while the latter is generally very nearly true. The energy required to move the body through distance S at speed V varies as RS or $K\rho V^2S$.

Two very important general principles are at once apparent from the above reasoning. First, the energy required to transport a body a given distance varies as the square of the speed at which it is moved. This is true in spite of the fact that the greater the speed the less the time required. So that the lower the speed of flight the more economical is the flight. This conclusion shows the fundamental disability under which high-speed flight labors in comparison with other means of transport, and it is only modified in practice by the fact that "time is money."

The second conclusion depends upon the common knowledge that the density of the air decreases with increasing altitude. At 10,000 ft., for instance, the density is 0.722 that at ground level, and at 20,000 ft. it is only 0.520 the density at ground level. It would appear to follow, therefore, that on general grounds, for economic flight the altitude of flight should be as great as possible. In practice the limit imposed on the altitude of flight is due to the reduction in power of the engine caused by the rarefaction of the air at altitudes and (or) the personal physical disabilities caused by the atmospheric conditions at high altitudes. To some extent the former limitation can be overcome by designing the engine specially for performance at altitudes, and the latter may also be partially overcome by suitable provision being made, but it would hardly appear at present that any provision for the physical needs, due to very high altitudes, of either pilot or passengers could form part of any commercial flying enterprise, and that there is, therefore, practically speaking, a limit to the altitude at which commercial flight can take place.

Proceeding now from the case of a plain body whose resistance varies as V^2—the case of the airship—to the case of the airplane it must be remembered that, in general, the altitude at which the airplane flies varies according to the speed of flight and that the foregoing reasoning only applies to flight at a given altitude. With the alterations in attitude which take place in practice the resistance coefficients of the body, struts, wires, etc., of the airplane generally alter very little, while the lift and drag coefficients of the wings both alter greatly. The

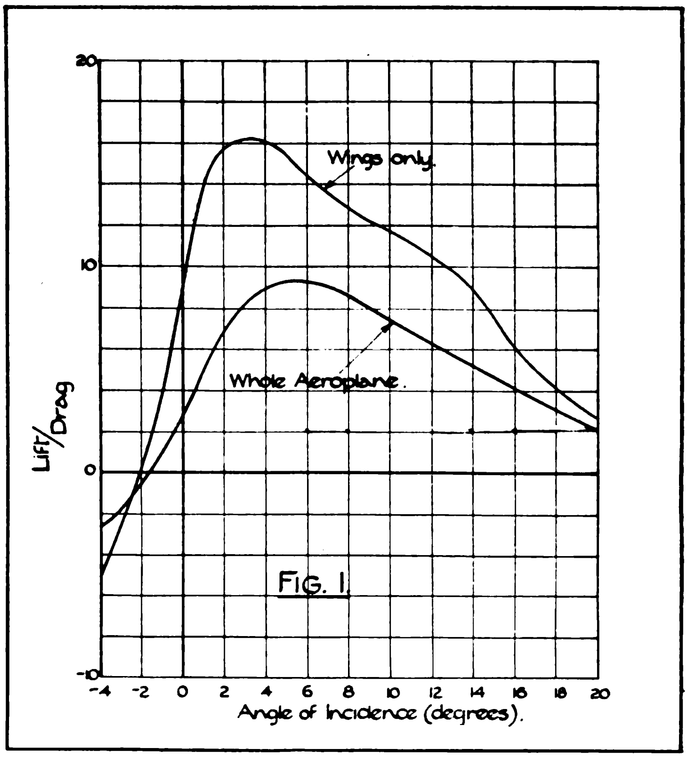


Fig. 1—Diagram showing variation of lift drag ratio with angle of incidence

total lift must, of course, remain equal to the total weight throughout the flight, so that as the attitude alters the speed must alter, an increase in the lifting power of the wings caused by increasing their angle of attack being accompanied by a decrease in the speed of the machine.

The ratio of the lift to the drag of a machine is one of its most important characteristics. Other things being equal, the greater this ratio the greater the aerodynamic efficiency of the airplane. For a given airplane the ratio has a definite value for each attitude of flight. Fig. 1 shows the general nature of the curve of lift-drag ratio plotted against angle of incidence of wings for a biplane. Two curves are given, one for the wings only and one for the whole machine. Such curves are generally derived from the results of experiments on models placed in a wind tunnel.

It will now be shown that the most economical speed of flight for any given airplane is that for which the attitude is the one corresponding to maximum lift-drag ratio for the whole machine. The work done in moving an airplane a distance S (relative to the air) when the resistance is D is equal to DS. If $W = L =$ weight of airplane, we have

$$DS = \frac{W}{L/D} \times S$$

and for a given distance S this is a minimum when L/D is a maximum. So that the most economical attitude for flight is that corresponding to maximum lift-drag ratio of the airplane, which attitude is generally not much different from that for maximum lift-drag ratio of the wings.

The above conclusion is true for any altitude, a fact which means that, aerodynamically, that there is nothing to be gained by flight at high altitudes with a given airplane. Other considerations, however, have to be taken into account in this connection. Suppose an airplane to be flying at its most economical altitude. In order that the lift of the wings may at all altitudes be equal to the weight of the machine the forward speed must vary inversely as the square root of the density of the air. Since lift and lift-drag ratio are constant the drag must be constant, and therefore the horsepower must vary with density in the same way as the forward speed; that is, the horsepower varies inversely as the square root of the density. From this reasoning two points emerge, each indirectly bearing on the economy of flight and showing why flight at the higher altitudes is preferable to flight just above ground, although aerodynamically the economy of flight is the same at all altitudes. Firstly, since the forward speed increases with altitude, there will be a saving of time by flying at the higher altitude, a very important consideration. And secondly, since the power required increases with altitude, as shown above, it will pay to fly at an altitude which utilizes or nearly utilizes the full power of the motor, since motors generally run most economically at about their full power.

Another method of considering the question of the best speed for economic flight of a given airplane is as follows:

Work done in moving airplane through distance

$$S = DS = \frac{DV}{V} \times S$$

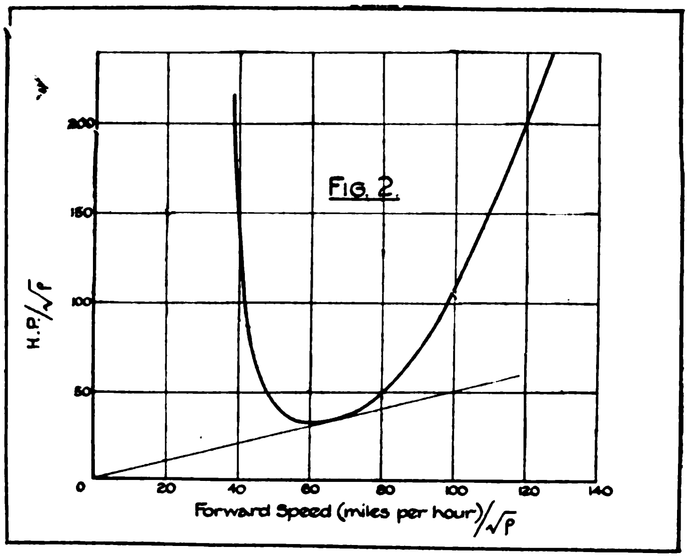

Fig. 2—Diagram for determining most economical speed of flight

That is, the work done varies as $\frac{\text{H.P.}}{V} \times S$ and is a minimum for a given distance when the ratio H.P./V is a minimum. This condition is illustrated by Fig. 2, in which H.P./$\sqrt{\rho}$ is plotted against $V/\sqrt{\rho}$, where ρ is the density of the air relative to the density at ground level. The figure thus applies to any altitude, change in density being allowed for by change in the scales of the coordinates of the curve. The most economical speed is found by drawing a tangent from the origin to the curve, and it will be seen that the most economical speed is only slightly greater than the speed for minimum horsepower. Thus, an airplane flying at its "ceiling" is flying at very nearly its most economical altitude.

It has now been shown that for a given airplane aerodynamically the maximum economy of flight is the same at all altitudes, but that this involves flight at speed varying according to the altitude. If the economy of flight of a machine of given weight is considered—as it should be—*for a given speed*—the problem as to the effect of altitude on economy becomes rather different. For economical flight the altitude must be always the same, namely that of maximum lift-drag ratio; therefore, if the speed is to be constant, the area of the wings must vary inversely as the density. But in spite of this fact, the resistance of the wings remains the same at all altitudes, since

$$D_w = \frac{W}{L/D_w}$$

where L/D_w is the lift-drag ratio for the wings. The size of the body remaining the same, its resistance will vary as the density and hence there will be a saving of power in the machine specially designed to fly at high altitudes.

To some extent this conclusion is modified by the fact that the machine which flies at the higher altitude has larger and therefore heavier wings, struts, etc., so that the *useful load* carried by this machine will be rather less than that carried by the machine flying at the lesser altitude; and, further, the larger wings mean more re-

Table Showing Economy of Power Due to Flight at High Altitude

Height in feet	0	2000	4000	6000	8000	10000	12000	14000	16000	18000	20000
Relative density ρ	1	.940	.870	.825	.772	.722	.678	.636	.596	.556	.520
Resistance of Body, etc. R = 200 × ρ	200	188	174	165	154	144	135	127	119	111	104
Total resistance = R + 200	400	388	374	365	351	344	335	327	319	311	304
Percentage Reduction on resistance at ground level	0	3	6.5	8.75	11.4	13.9	16.1	18.2	20.2	22.2	24.0

sistance other than wing and body resistance. But the weight of the wings and the resistance of parts other than wings which varies with wing area are each only a small proportion of the total weight and resistance, and the economy to be gained by designing for high altitude at a given speed is nevertheless considerable.

It is not possible in the present article to give any exact figures as to the magnitude of the saving which could be effected by designing for high altitudes. This would depend—among other things—on the type of airplane and the forward speed desired. In fact, in order to arrive at accurate figures in any particular cases would practically mean roughing out weights and resistances for each special design. A rough idea as to the order of magnitude of the saving may, however, be arrived at by some very simple calculations for a particular case. Take, for example, an airplane of weight 3200 lb., say, whose lift-drag ratio at ground level is 16 for the wings only and 8 for the complete machine. The resistance at ground level will then be 200 lb. for the wings and 400 lb. for the complete machine, thus making the resistance of the body, etc., 200 lb. The accompanying table shows the percentage saving in resistance (and consequently horsepower, since the forward speed is supposed constant) over that at ground level at altitudes up to 20,000 ft. In this particular case, in which at ground level the resistance of the body, etc., is equal to half the total resistance of the airplane, the percentage reduction in total resistance at any particular altitude is equal to half the percentage reduction in the density at that altitude. The condition that the resistance of the body, etc., is equal to half the total resistance will in general not be very far from being realized in practice, and so the figures of the table give an indication of the order of magnitude of the saving which may be effected by designing specially for altitude. It will be noticed that the figures of the table are independent of the forward speed, and in this connection there are two points which should be remembered. They are the questions of landing speed and rate of climb. The airplane designed to fly at its most economical altitude and to use its full power at ground level would, as Fig. 2 shows, require only very slightly less horsepower at the altitude for minimum horsepower. There would thus be only a very small reserve of power for climbing and the ratio of climb would be very slow indeed. Again, with the machine designed for flight at ground level the forward speed is strictly limited to values which are not very high in order to keep the landing speed down. The maximum lift coefficient of wing section is generally about double its value at the altitude for maximum lift-drag ratio; which means that the landing speed is about equal to the economical speed divided by $\sqrt{2}$. Thus, if the chosen speed of flight is 100 miles per hour the landing speed is equal to 71 m.p.h., a value which is considerably on the high side.

But consider now the airplane which is designed for the same forward speed at an altitude of 8000 ft., say. Its landing speed will now be reduced from 71 m.p.h. to 71×0.772, or nearly 54.5 m.p.h., and the rate of climb at ground level will now be of fair magnitude. For the horsepower required for the 8000-ft. machine when at ground level will be $\sqrt{\rho}$ times that required at 8000 ft., that is, 5.7 per cent of the power will be available for climb. In the case of the particular airplane chosen as example, this would give a rate of climb of 111 ft.-min.

Obviously, then, machines designed for economical flight at low altitudes are not practical machines, and the effect of altitude on economy of flight should be considered by comparing the performances of machines at high altitudes with those for altitudes of perhaps 6000 to 8000 ft.

Kessler Super-Charge Engine Developed for Automobile Purposes

(*Continued from page* 1293)

uses a counter-balanced crankshaft, and this same type of counter-balancing will be used on the 3¾ by 3¾-in., six-cylinder automobile engine, of which sample engines are now being made up. Air by-passages are so arranged that every down stroke of the piston is utilized for producing crankcase compression. As compared with the normal form of engine, it will be slightly higher, due to the increased combustion chamber volume. The weight per unit of displacement will probably run about the same as that of the ordinary type of engine, and in general appearance there will be no marked difference. The automobile type should weigh approximately 5.3 lb. per hp.

A representative of AUTOMOTIVE INDUSTRIES saw an aviation type Kessler engine on the block, operating first as a normal poppet valve type and then with the super charge admitted. The difference was remarkable, for, although the valve timing was a little early in the intake cut-off for the ordinary poppet type engine, yet it gave a very creditable performance. As soon as the supercharge was admitted, however, the speed of the engine rose remarkably, and it was possible to carry a much higher load on the engine. While it is impossible for the representative of AUTOMOTIVE INDUSTRIES who witnessed the test on the engine to accurately state the results of the cushioning effect on the bearings due to crankcase compression, it is positive that on the old automobile type engine employed in the experimental car the vibration is remarkably low for a four-cylinder engine of any type. Claims made by the inventors of this engine and taken seriously by car makers who have examined it, state that bearing life is materially increased by the effect of the cushion.

The engine now being developed for car work will have a proportional valve capacity which is probably the largest ever used in automobile practice. It will have two intakes and two exhaust valves per cylinder, each valve having 1½ in. clear diameter, although the bore of the engine is only 3¾ in.

Glued Part Failures Not Always Due to Glue

GLUES are often blamed for failures for which they are not responsible. Tests made at the Forest Products Laboratory of the U. S. Forest Service at Madison, Wisconsin, show that properly handled commercial glue develops a shearing strength greater than that of most woods.

The average glue user prepares his glue with reasonable intelligence but commits atrocities in preparing surfaces to be glued and in handling pieces after gluing. To get full strength from any glue, proper surface contact is imperative. Good glue will adhere fairly well even with poor surface contact. Joints of this kind possess, however, inherent weakness and the added disadvantage that they are more liable to ruin through bacterial action than tight joints, since the glue in them is more exposed.

The proper application of pressure is important in all glued work, but doubly so in the manufacture of plywood. Securing proper pressure involves keeping cauls and press in first-class condition and using them skillfully.

Tractor Design from the Operator's Viewpoint

Criticism and Suggestions Based on Extensive Tractor Experience on Large Western Ranches

By Arthur B. Domonoske

IN the following article I am giving the side of the design as the operator looks at the result and not as the designer must necessarily do in laying out the machine. Shop practice must guide the designer to a large extent, while to the operator the necessity of keeping the machine running is the paramount consideration. My experience has been mostly in the Far West and with the track-laying type of machine, so I shall confine my attention to that locality and to that type of machine.

As a foreword it might be well to mention that on the western ranches the tractor has been adopted not for any inherent love for machinery on the part of the rancher, nor because of the glib talk of the salesman, but of dire necessity. With the increase of wages and the shortening of hours in the cities, the better men of agricultural communities drifted into city trades and occupations.

The hours on the ranches were long, the sleeping accommodations were poor, no provision was made for personal cleanliness, and while the meals were generally of good quality there was no variety of menu. No amusements were possible except occasional drinking and gambling, and added to these were the great difficulties in the way of a hired man starting in business for himself. Therefore, it became increasingly harder to obtain good teamsters for "eight-mule" teams at $1.50 and $2 per day, but tractioneers or "caterpillar skinners," as they are called in ranch parlance, could be obtained for $4 per day, and found.

A 75 or 80 b.-hp. tractor is supposed to do the work of four eight-mule teams, so an engineer at $4 and a plow tender at $2 would replace four teamsters at $1.50 each. The labor costs would therefore be alike for teams and tractor.

Fuel Costs

As far as fuel and oil costs are concerned on most ranches, it seems from the meagre figures available that it is immaterial whether you raise a certain amount of feed for the teams or whether you raise the same amount of grain and sell it to buy fuel and oil.

The first cost of the tractor and that of the four eight-mule teams were not far different, so the deciding feature was the ability to keep the outfit going. Had there been plenty of drivers the tractor would have been greatly delayed in getting a foothold, for it has been my experience that four *well-driven* eight-mule teams will out-plow the 75-hp. tractor in average plowing. The reason is that, in the case of the teams, there are four separate units and a temporary accident to one rig does not delay all of them, and, in addition, the rigs are more flexible and can get in and out of sharp corners better. In harvesting, the four teams are combined in one unit and have no such advantage over the tractor, but, on the other hand, the motion of the tractor is steadier, it makes turns quicker, and gets closer to ditches.

From this you may see that the essential thing for the operator is to keep going. The tractor, having been forced upon the rancher, is looked upon as a necessary evil and undeserving of sympathy, while the tractioneer is a man too lazy to drive a team and who is continually breaking into the bank account for salary and repair bills.

It must be further remembered that the tractor operator may be miles from a well-equipped machine shop and must rely on his collection of hand tools. His equipment for lifting consists of two 2-in. jack screws, whatever blocking there is lying around loose, and man power. Chain falls are rarely found on the ranches.

We will now take up some of the points of design that concern the operator in his task of "keeping her going" and will somewhat subdivide them.

The Motor

The carbureter has been advertised as the "heart of the motor," and likewise the motor may be considered the heart of the tractor. The tractor operator tries above all things to have a sweet-running engine; it is his source of power and it is vital that it shall run, and run well.

If time permits, the rest of the outfit is given some share of the attention, but the engine is first, last, and all the time the center of attention. One bugbear is that of heating, for, while the majority of automobiles are overcooled, the tractor is not. Here we have no letup of the load but a constant, steady drag. There is no chance to stop and let your engine cool off, nor to change the cooling water; therefore your radiator must be ample to care for the worst conditions possible.

It is not an uncommon thing to run when the thermometer registers from 90 to 120 deg. Fahr. in the shade and your tractor is in the sun. With the incoming air at 120 deg. Fahr. you have no great difference in temperature between the air and the water and must therefore rely on plenty of radiating surface and on the fan sending a steady volume of air through the radiator. The rate at which the water flows through the radiator tubes and the water jackets also greatly affects the cooling. A slipping fan or pump belt plays havoc with the cooling; therefore, these two should be run by extra wide belting or be positively connected to the engine.

The fan, if not belt-driven, should have a slip clutch to prevent blade damage. The pump must be located where it is under sufficient head on the suction side

to insure pumping even with very hot water. Also, most operators would appreciate a location where the pump may be packed without either standing on your head or else lying on your back under the machine and receiving the accumulated mud and grease from the frame and the hot water from the pump in your eye. Where the fan and the pump are belt-driven it might be well to remember that the belt pull may be considerable and that bearings should be ample and well lubricated.

Cooling is also made harder by the presence of scale-forming salts in the water which deposit in the water jackets and in the radiator spaces. At times the water must be taken from irrigation ditches and organic matter is introduced into the system, which blocks up the water passages, and therefore some means should be provided for cleaning these. The dust settling on the fins of the radiator tubes will cut down the transmission of heat through the tubes, and allowance should be made in the area allowed for cooling.

Care should be taken that the pump delivers water equally to all the cylinders, so some may not be heated while others run cool. Some companies use a tank in connection with the radiating system, and here it should be remembered that, while it is a nice thing to place it out of sight, there should be some way to remove it without taking off most of the decking and nearly all of the main drive shafting. The constant jar and bad water will make any tank leak in time.

Soldered Joints

Soldered joints in the radiator should be reduced to a minimum and allowance should be made for the expansion of the tubes. One western company uses packed joints with threaded glands, similar to those used in steam engine condenser practice, and from the operator's viewpoint it is an excellent system. The radiator should also be spring-mounted, to take off jars, which are considerably larger than most people imagine. A sight feed glass and a petcock should be located in the system so that the operator can tell whether the water is circulating properly.

The injection of water through the intake manifold has a tendency to keep the engine cool, but the proper regulation of the amount to be fed may give difficulty.

Another point that might be considered is that the heated air from the radiator, which is usually blown over the motor, is not very effective in cooling the cylinders. It might be better for the engine, and would be much better for the operator, if this were diverted from the motor. A blast of air at the outside temperature would help in keeping the cylinders cool.

Although it would add to the complication, some means of keeping the crankcase oil cooled would help wonderfully in keeping the motor temperature down.

A tractioneer hates to shut down a hot engine, because of the difficulty in starting it again. Sometimes a little oil poured in the air intake to the carbureter will aid greatly in cooling a hot engine, but care must be taken not to choke it with too much. The final method of cooling is to shut down and open up the crankcase and allow the air to circulate through the case freely. This is bad, owing to the dust that may be blown in. Starting the motor will be hard, due to the hot walls reducing the weight of charge entering the cylinders and also to the lubricating oil running down off the piston and the cylinder walls, thus making poor compression.

Aside from the foregoing considerations there is heating due to improper mixture, air leakage, etc., which are due to the engineer's negligence and must be charged up to the human element. The other extreme of overcooling in winter can be regulated by shutter control on the fan housing or by bypassing the water from the pump, either by thermostatic or manual control.

Next to heating, lubrication may be said to be the operator's worst trouble, although he is often unaware of the real cause. Most operators do not change their oil often enough, either because of lack of knowledge or of the owner's objection on the score of cost. The tractor manufacturer is largely to blame for this in not impressing on the owner the necessity for changing oil. The crankcase oil receives considerable carbon from deposits that form on the lower side of the piston head, due to the heat charring the oil, and which in time jar loose and fall into the oil pits. Dust also gets in during filling up with oil at night and in testing bearings. It is somewhat of a question as to whether a filler cap should be provided or whether a man should take off a side plate to put in oil. By taking off the side plate the bearings are more closely watched, and all tests for bearing looseness should be made on warm engine. In either case there should be no projecting ledges to catch dirt and allow it to fall into the oil when either the cap or door is removed. Of course, the operator should wipe this dust off, but when a man draws up alongside of a tank wagon just as the sun is going down, with an hour's work ahead of him in filling up and greasing, he is apt to let this slide.

A combination of splash and force feed lubrication seems to me to be the best solution of the lubrication problem. I doubt if the main bearings get all the oil they need with the constant level splash, while with a full force system failure of the pump would lead to speedy damage unless noticed by the operator. Either a gage or a sight feed glass should be provided, so that the operator may know whether the pump is working or not.

Crankcases

Crankcases which do not have sufficient drain plugs or have pockets that must be baled out and finally cleaned with rags or waste take up a needless lot of time in changing oil. As the oil pump periodically gets clogged with foreign substances, it would be well if it were so shaped and located as to be easily accessible. The oil pump should be at the lowest point in the system, so that the oil may get started immediately and so that the pump will deliver oil as long as there is any left.

Where overhead rockers are used with "valve-in-the-head" motors a cover should be provided to keep dirt from settling on the stems of the inlet valves and by its abrasive action soon cause trouble from air leakage into the inlet ports. Provision must be made for rocker-arm and valve-stem lubrication. If possible, this cover should be easily removable to allow turning the valves about a quarter turn each day to prevent uneven seating and thus making the valves run longer between grindings.

The governor working parts should by all means be dustproof and well lubricated. Also, the governor spring should be worked within a range of stresses where it will not be continually changing in value. A surging governor is extremely bad in pulling a ground driven harvester, which requires a steady gait to keep an even motion on the cylinder and fans. In exposed governors this surging is often caused by the gumming up of the moving parts with dirt and oil.

As many parts as possible should be oiled without the use of compression grease cups, to save time in filling up.

One make of tractor has over forty grease cups of various sizes. However, it should be remembered that there are places where the compression grease cup must be used, as a very effective way of keeping dirt out is to have plenty of grease on the inside of a bearing.

All gears should be enclosed and should be amply supplied with lubrication. Much grease is thrown off by exposed gears, and dirt collects in the grease that does stay on. Aside from the wearing of the gearing it is hard to keep your tractor clean with a grease-slinging device operating all the time, and a dirty tractor is the beginning of trouble.

Some of the tractor makers are fitting dust strainers on the intake air to the carbureter, and all of them should. Most people do not realize the amount of dirt that gets into the cylinders through the carbureter.

Control

A simple hydraulic clutch and speed control or a correspondingly simple magnetic control would be a welcome thing for the tractor operator. At present a man is between the two fires of starting with a jerk or burning out the clutch by slipping. In crossing ridges and ditches the clutch must be released to prevent the front end from rising and dropping suddenly. All of this causes wear on the lining. A more liberal design would be better than the present, and most tractors are designed for too great a pull on the levers. Exercising a pull at frequent intervals and only once or twice an hour are entirely different propositions.

Another fault is that there is too much spring in the levers. Rim or band clutches in which two opposing toggles must be equally adjusted for correct action should have some equalizing device independent of the clutch adjustment. Since clutches in the neighborhood of gears are apt to be covered with oil, in spite of the operator, they should be designed to carry the load on the assumption that they are to run in oil.

Steering should be made as easy as possible and power steering gear should be fitted to the larger tractors, especially if there is much weight on the front end. However, it is possible to steer 75-hp. tractors by hand without excessive exertion if the steering gear is built correctly.

Tracks

Means must be provided to allow the operator to keep his sprockets and tracks in correct alignment. A round-head track bolt, even if fitted with a square shoulder fitting in the track shoe, is mean to handle, as it is only a short time until the shoulder wears enough to turn. Either a solid link and shoe or some means of bolting on so that the bolts will stay tight must be developed, especially for road work.

Starting

For the average tractor operator, starting either by bar or by turning the flywheel by hand is not a serious thing under ordinary circumstances. However, it is not an easy thing for a light-weight man, and on a cold morning or with a hot motor it is hard work for the best of them.

As there is no housing of the tractor at night, everything is thoroughly cold on the tractor in the morning. The oil is thick and the motor turns over hard, while the gasoline and distillate are in poor shape for vaporizing. Engineers use various methods for starting on cold mornings, some of them dangerous.

1—Prime each cylinder with *gasoline*, either through priming cocks or through spark plug holes. Turn engine over several times with ignition off and allow to stand a while. This allows some of the gasoline to vaporize and diffuse through the mixture. Then prime engine again through priming cock and turn over with ignition on. Under ordinary conditions the engine will start the first time, but on cold mornings more severe methods must be used.

2—Put the gasoline priming can in hot water. I have seen engineers put the can in a fire or hold it over a blowtorch until the vapor begins to distill off. Prime with this warm gasoline.

3—Warm up intake manifold and inside of cylinders through spark-plug holes with blowtorch; but care must be taken to stand clear of any possible flame from cylinders. Heat spark plugs.

4—Pour gasoline or distillate over the heads and manifolds and set fire to it. Care must be taken that there are no pipe line or tank leaks near the flame.

5—Prime with a mixture of gasoline and ether. Too much ether will lift the heads.

6—Above all do not prime too much, as the raw gasoline will wash the oil away from the rings and spoil the compression. Sometimes priming with a mixture of oil and gasoline or a little oil alone helps greatly.

The fact that these severe and more or less dangerous methods are in common use shows the necessity for some good starting system combined with a method of getting an explosive mixture into the cylinder independent of the regular carbureter.

Fire Hazards

Although many fires were started before tractors were used and many are blamed on tractors where something else is responsible, the fact remains that a tractor in a grain field, dry as tinder, is a source of danger. Fires may be started by pieces of carbon thrown out of the exhaust, by pieces of hot wire blown off the spark arrester, by chaff or straw falling on the hot exhaust manifold and dropping off into the stubble, or by a pop back in the carbureter in starting, and especially if the operator squirts gasoline into the air intake, as most of them do.

Some owners place a 30-gal. stove boiler, with the top head removed, on the front end of the tractor and bring the exhaust pipe of the engine down into the tank, so the exhaust gases must make a 180 deg. turn to get out. The lower portion of the tank up to about 6 or 8 in. of the end of the exhaust pipe is filled with water which quenches the hot particles of carbon, which are too heavy to turn with the gases. This tank, while very effective in catching carbon, increases the back pressure on the engine and thus adds to the heating troubles.

In addition a fire extinguisher is carried on the engine and one on the harvester. A can of water filled with wet sacks is also carried on the tractor, and on windy days a man follows the outfit on a saddle horse to watch for fires. For quick action he carries a wet sack on the saddle strings. On very windy days the outfit stops.

General Operation

A gas tractor is excessively cold in winter and very hot to work on in summer. In the colder climates provision should be made for a cab, but care must be taken to keep out exhaust gas from this cab. If the hot air from the fan were not driven back on the operator it would be cooler in summer.

A clear view ahead of the tractor should be provided, as it helps wonderfully in coming up to ditches and corners.

Clutch brakes should be provided to keep the master clutch from spinning if the gears happen to be in the neutral position.

Matthews Full Automatic Lighting Plants

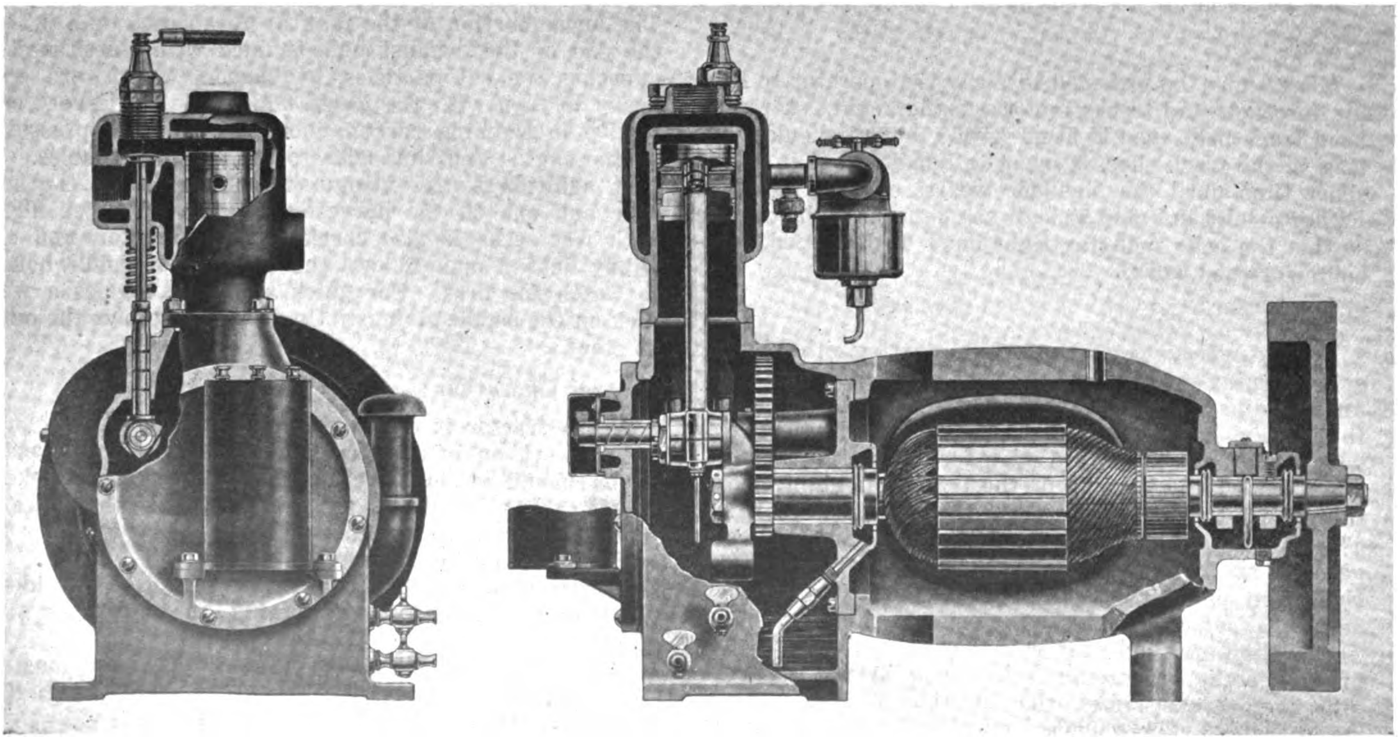
Made in Capacities Ranging from 300 Watts to 6 Kilowatts—Start and Stop Automatically, as Required by State of Battery Charge or the Amount of Load on the Line — Plain Generator Set Also Furnished

By P. M. Heldt

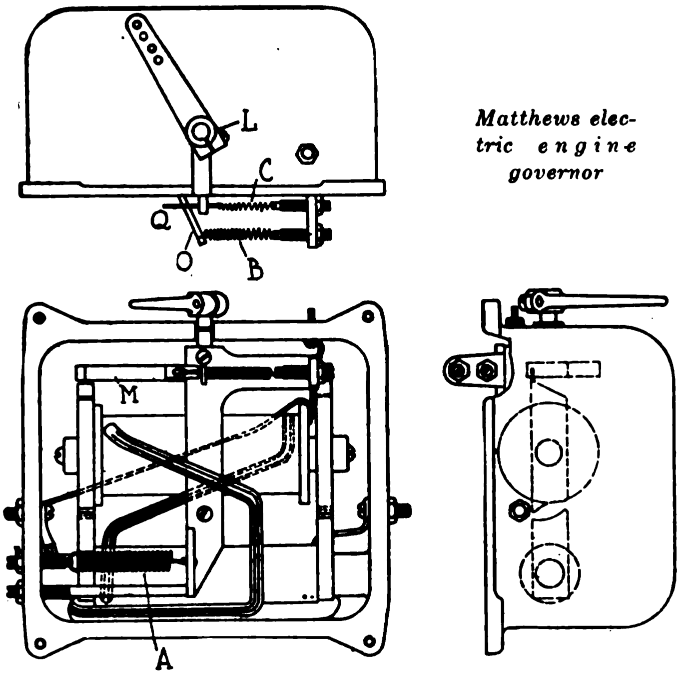
THE Matthews Engineering Co. of Sandusky, O., manufactures electric lighting plants in sizes ranging from 0.3 K.W. to 15 K.W. The line comprises automatic plants in 0.3, 1, 2, and 6 K.W. sizes and non-automatic plants of 1, 5, 10 and 15 K.W. In addition to these, a 12 K.W. plant is made, which comprises two 6 K.W. automatic generators connected in parallel. The smaller plants are used largely for lighting farms and private country houses, while the larger units find application in lighting and furnishing motor power for large estates, ranches, stores, dairies, churches, small towns, moving picture theatres, etc. It will be be noted that the automatic feature is used mainly in connection with the smaller plants. The reason for this is that with large plants there is usually some one who is looking after the installation all the time, and automatic control is not then essential.

All of the automatic plants are, naturally, very much alike in design, so far as their electrical features are concerned. We have selected the 1 K.W. and the 300 watt plants for description. The former comprises a single cylinder, water cooled, upright engine, having cylinder dimensions of 3 x 3 in. The cylinder is of the "L" head type, with integral cylinder heads, the crankcase being cast separately. There is a large hand hole with cover plate on the side of the crankcase through which access can be obtained to the crankshaft and connecting rod bearings. The plant is of the 3 bearing type, that is, there are two bearings in the engine and one in the generator. The engine bearings are made of S. A. E. specification babbitt, and are extra large. The armature shaft is piloted in the end of the engine crankshaft, and is driven from the latter through a sort of jaw coupling. The crankcase is cast with two large openings on the end, over which are bolted the bearing plates. In order to insure absolute alignment of the engine bearings, these are line-reamed. The generator is held in alignment with the engine by means of a connector flange to which the former is bolted.

Owing to restrictions on the amount of gasoline which can be kept within a building, the gasoline tank



Sectional views of 300-watt generator



Matthews electric engine governor

from which the fuel is drawn is located outside the building, and a 5 ft. length of copper tubing is furnished with the plant, by means of which connection can be made from the storage tank to a Stewart vacuum tank, which is secured to the cooling tank. The latter is an electrically welded steel barrel, 19 in. in diameter by 34 in. in height. A Schebler Type B carbureter is fitted, which is controlled by an electric governor. This governor has both a shunt and a series winding. It is so designed that when the generator is carrying only battery load, the generator voltage is maintained to give the proper charging rate; that when there is a lighting load in addition to the battery load, the throttle will be opened wider and more current will be generated to take care of this additional load. Battery charging is continued until the charge is complete, when the plant will be automatically shut down.

The governor consists of an electro-magnet with rotating or rocking armature to the shaft of which the governor lever is connected. The governor has both a shunt and a series winding, each winding being on a separate spool. There are three adjusting springs on which adjustments are made under the following conditions: If the governor fails to open the throttle sufficiently as the load is thrown on, and in consequence the battery begins to discharge, spring A should be slightly weakened: if when the plant is started the armature M does not assume its normal running position, that is, if the lever O does not come up against the far end of clip Q, then the adjusting spring B should be weakened; if, under normal running conditions with the battery connected to the plant, clip Q should not be up against the stop, then the adjusting spring C is too weak and should be strengthened.

It will be noted that the governor lever is provided with a number of holes so that its effective length can be varied, and the lever can also be adjusted on its shaft by means of the clamp screw at the hub.

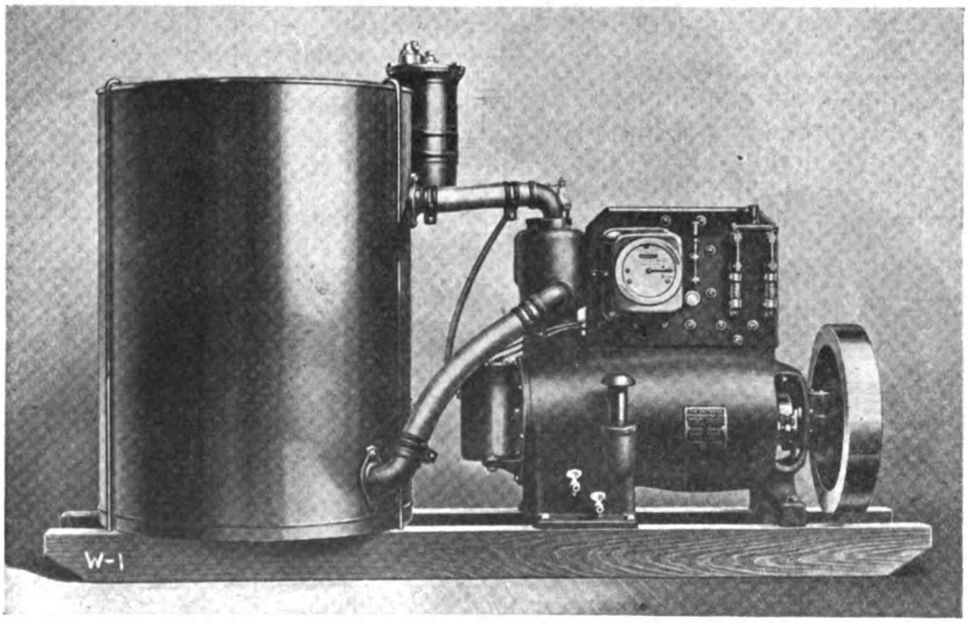
Ignition is by a 32-volt vibrating coil in conjunction with a timer. The spark plug is screwed into the valve cap. Lubrication of the engine is by splash. A large crankcase oil reservoir is provided and there are hand holes in the crankcase on both sides. Four feet are cast on the crank chamber by means of which the engine is supported upon a channel iron frame.

Ordinarily, starting is effected electrically, but for emergency cases a starting crank is provided, the shaft of which passes underneath the cooling tank to the end of the supporting frame. Cooling water is circulated by thermo-siphon action, the connections between the jacket and tank being of ample dimensions.

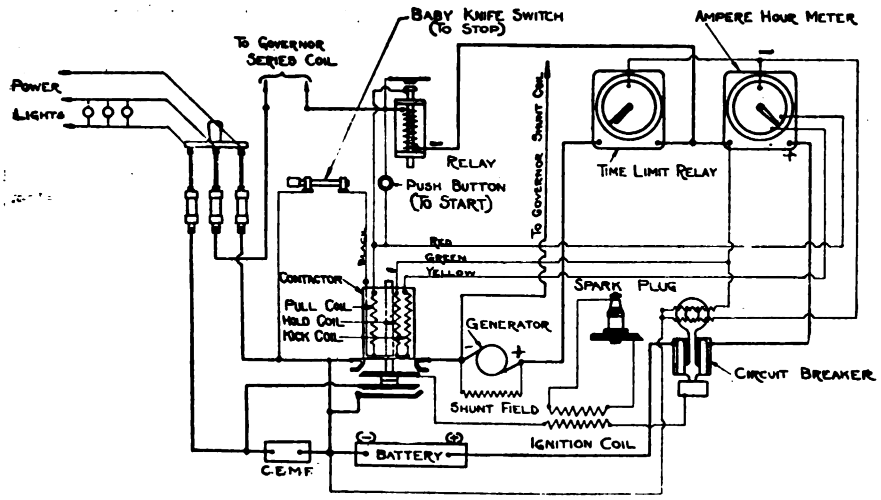
The generator is of General Electric make, and is a 4 pole type with laminated fields. Wave armature winding is used, and there are four brushes on the commutator. The outer end plate of the generator is cast with feet which rest on a cross member of the frame. The generator is wound for 32 volts, supplying current to a 16-cell Willard battery.

The battery consists of 16 cells and 1 counter-cell, and has a capacity of 72 ampere-hours. The generator set occupies 60 x 21 in. floor space, is 42 in. high and weighs complete 480 lb., while the battery occupies 39 x 18 in. floor space, is 21½ in. high and weighs 271 lb.

The 300 watt outfit is probably the smallest commercial electric lighting plant ever manufactured, and its design has been reduced to the simplest form. Thus, the generator field frame and the engine crankcase are a single casting; likewise, the engine crankshaft and the armature shaft are one and the same piece. The set comprises a single cylinder, vertical, water cooled engine of 2 in. bore by 3 in. stroke, with integral cylinder head. An overhanging crankshaft is used, which is hardened and ground, and held on by taper, key and nut. The plant is a two bearing job, having one bearing between generator and engine, and one generator outboard bearing. Non-Gran bronze bearings are used with a ring oiler on the generator bearing. The connecting rod is made of bronze with



Three-hundred-watt plant complete



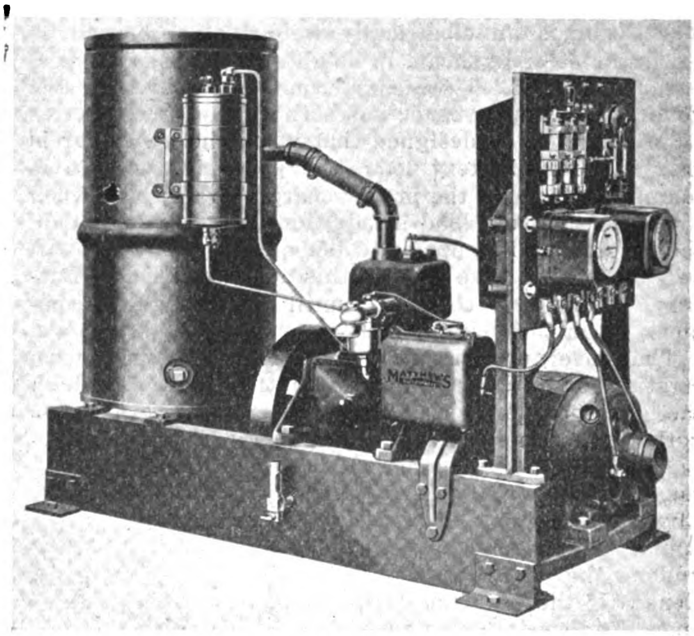
Circuit diagram 1 *K. W. set*

adjustable bearing, and has an oil thrower secured to it. The crank is counterbalanced so as to insure smooth running. On the cam-shaft bearing there is a spiral groove which has a tendency to pull the oil in and keep the engine clean. Spur gears are used for the cam-shaft drive, the large gear being made of cast iron, and the pinion of steel. A mushroom type cam follower is used, and an adjustable tappet. The clear diameter of the valves is 15/16 in. The valves have cast iron heads and steel stems. The piston has 3 rings and is fitted with a tubular piston pin which is hardened and ground.

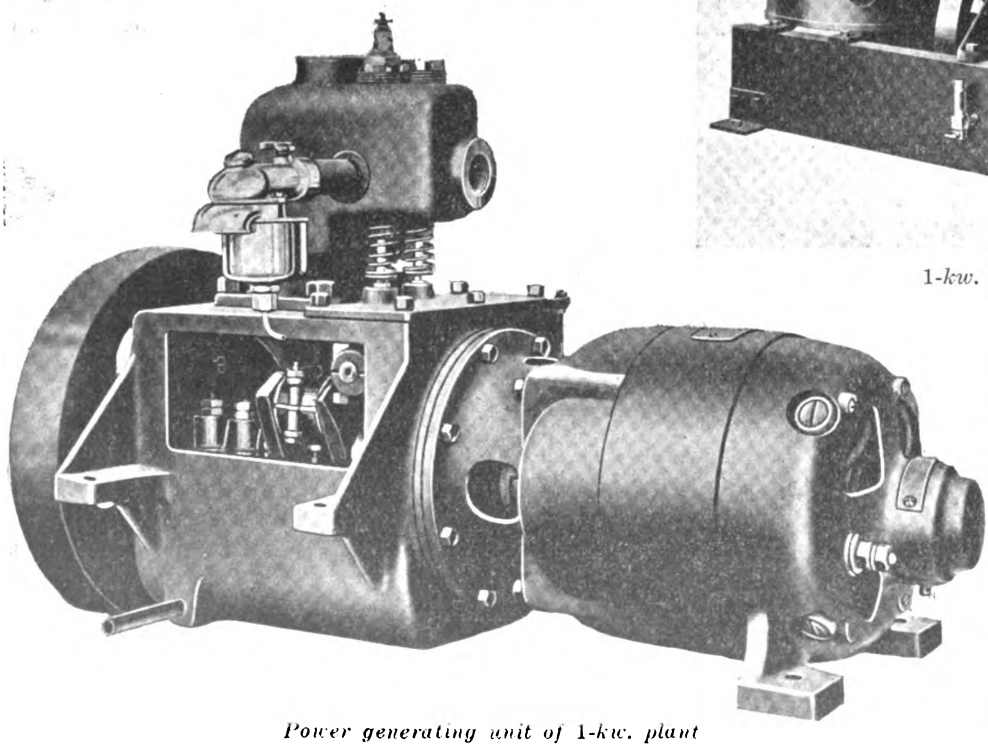
A Stewart vacuum feed system is supplied and thermo-siphon circulation of cooling water is used. The cooling tank measures 16 in. in diameter by 24 in. in height. The carbureter is the Schebler model B, and is provided with a throttle lock device so the generator output cannot exceed 300 watts. Otherwise, if the engine were run under full throttle, it would be possible to get an output of 425 watts.

Ignition is by a 32 volt, single spark, non-vibrating coil, the interrupter being mounted on the end of the camshaft. The flywheel is held on by a taper and key. Oiling is by splash. There is a check valve in the oil return pipe from the main bearing so that the crankcase compression cannot force oil up this pipe and cause excess lubrication. A vacuum type of breather is used, that is, a breather with a valve which opens when there is an excess of pressure in the crankcase and closes when there is a partial vacuum.

The generator is of the two pole shunt-wound type, and has an extra large armature shaft. The field frame and the engine crankcase being one casting the boring of the armature tunnel and of the two main bearings can be effected in one setting. There are two main brushes on the commutator which are in the regular position, 180 deg. apart, and in addition there is a third brush slightly behind one of the main brushes. A voltage of 36 is obtained between the main brushes, and these are connected across the storage battery, while a voltage of 32 is obtained between one main brush and the auxiliary brush, and the lighting load is connected between these two brushes. The flywheel is located outside the generator and has a weight of 22 lb. There is no flicker of the light with the engine running at 1250 r.p.m.



1-*kw. plant complete*



Power generating unit of 1-*kw. plant*

The switchboard and instruments are much the same as on the other system. Lugs are cast on the field frame for holding the switchboard. The ignition coil is mounted on the end of the engine crankcase and is therefore close to the interrupter and the spark plug.

In the foregoing description the term "automatic" has been used repeatedly, and it may be well to explain exactly what this term covers as applied to this plant. In the

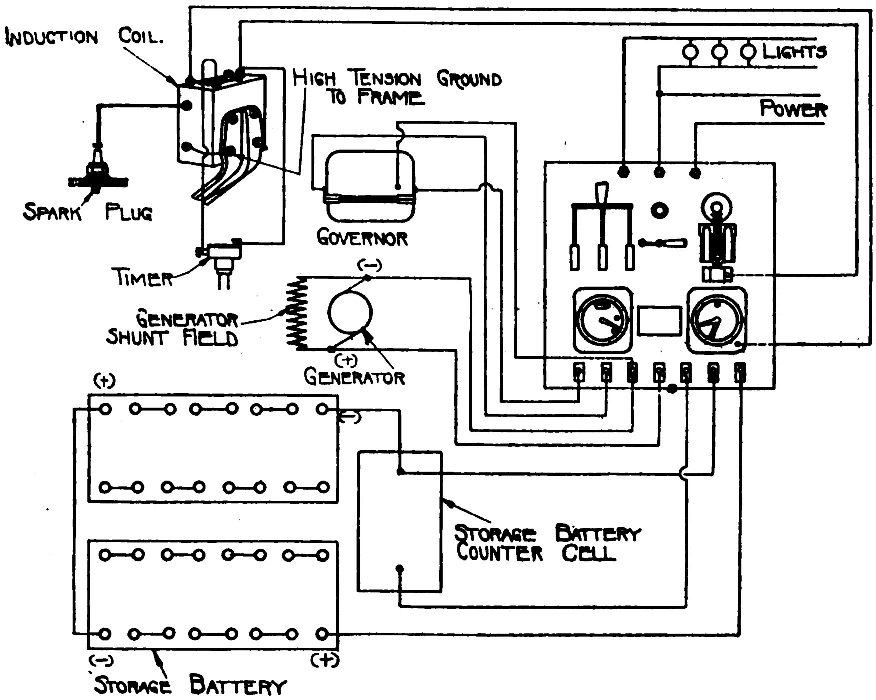


Diagram of connections 1-kw. set

first place, as soon as approximately 15 per cent of the battery charge has been withdrawn, the engine will start automatically and begin to recharge. If only a few lights, say 10 or 12, are turned on they will be supplied with current directly from the battery and the plant will be idle until 15 per cent is taken from the battery. If a larger number of lights are turned on, say from 15 to 20, the generator will recharge the battery in the usual way, but when a state of full charge is reached it will not stop unless some of the lights are turned off. If an electric motor is switched on to the circuit the engine will immediately be started, and the entire load will be carried by the generator, irrespective of the state of charge of the battery. Once started, the engine will not stop until the batteries are completely charged, and as the generator carries all the heavier loads, even if the batteries are entirely full, a slow overcharge is obtained which keeps the battery in good condition.

The automatic features of the Matthews lighting system are based on the Sangamo ampere-hour meter and an overload relay. All current passing into and out of the battery flows through this meter and causes the indicator hand of the instrument to turn on its dial. The complete discharge would move the indicator hand about one-third around the dial. Contact points are secured to the dial plate in the positions corresponding to an empty battery, to a full charge, and to an 85 per cent charge. When the battery is being charged, the hand of the meter turns in a clockwise direction.

On discharge as soon as the meter hand reaches the "start" point the engine is started and begins to charge. Of course, not as much current can be taken out of a battery as has to be put into it during the charge, and in order to make up for the difference, the ampere-hour meter is so designed that its hand moves from 20 to 25 per cent slower on charge than on discharge, for a given rate of current flow. As already explained, if there is only a very small lighting load on the circuit when the battery is fully charged, the plant will be shut down. However, if a lighting load on the circuit is 17 amperes or over the plant will continue to run, and in consequence some additional current will flow into the battery. When the charging operation is over, the meter hand is always at "full," corresponding to the condition of the battery. It takes approximately one hour to charge the battery from the time the engine is started until the meter hand reaches the "full" stop.

There is another condition which must be provided for in a mechanism of this kind, in order that the charge of the battery may always be maintained. It is well known that when a battery is standing idle for a considerable period there is always a slow leakage of current. This leakage current, of course, does not flow through the ampere-hour meter, which consequently does not show the discharge of the battery. To take account of this discharge by leakage, the ampere-hour meter is provided with a thermocouple, which causes the disc of the meter to slowly revolve in the discharge direction, so that every 4 or 5 days the plant will automatically start and recharge the battery, even though no lights are ever turned on and no current is consumed.

One of the illustrations herewith shows a complete wiring diagram of the plant, in which are indicated not only the connections between the generator, battery and load, but also the connections of the ignition system and the electric governor. All of the instruments are mounted on a switchboard which has an elonite asbestos base. These instruments include a contactor, an overload relay and a circuit breaker. the ampere-hour meter and a device of the same class known as a time limit relay. The contactor is in the form of a solenoid switch with three coils. One of these is referred to as a pull coil, the second as a hold coil, and the third as a kick coil. The engine can be started in several different ways, one way being by means of a push button on the switchboard. Normally, the engine is started by the ampere-hour meter. When the hand of this meter comes around to the starting contact the circuit is closed through the pull coil of the contactor, and the battery is thereby thrown into circuit with the generator, starting the latter as a motor. The ignition circuit of the engine is also closed through the starting contactor, so that the "spark" is on the moment the engine begins to turn over.

As above pointed out, when sufficient current is being used in the consuming circuit the engine will start, irrespective of the position of the hand on the ampere-hour meter. This is effected by a device called an overload relay—an electro-magnetic switch through which flows all of the current supplied by the plant. When the plunger of the relay is strong enough it pulls it up, thereby closing the circuit through the pull coil of the contactor, which starts the engine.

In addition to the apparatus described above, the switchboard contains a time limit relay, the function of which is to open the battery circuit in case the engine for any reason should fail to pick up its cycle while it is being cranked by the generator. This would happen, for instance, if there was no fuel in the tank. When the battery is discharging the hand of the time limit relay turns clockwise, and vice versa. However, when the battery is being charged the hand can only

Four-Year Range of Wages in the Automotive Industry

Influence of the War Upsets the Basis of Comparisons Previously Employed—Seasonal Fluctuations Still Obtained

WASHINGTON, June 7.—Wages in the automobile industry were increased from $2.50 a day average in 1915 to $4.65 a day average in 1918. These figures are obtained from reports made to the Department of Labor monthly by automobile manufacturers. The number of companies reporting range from 36 to 52.

The accompanying charts were compiled from these reports and present the wages, numbers employed, production and selling prices in the automobile industry, the average daily wage and the average daily number employed, the prices of basic commodities, and the wages and number employed in other similar industries.

The tables show the wages and number employed in the automobile industry only. For the sake of comparison, where months of different years are used to obtain percentages, reports from the same factories only were used, regardless of the number filed.

In accounting for increase of wages in the industry many factors must be taken into consideration. The first cause undoubtedly was the effort to meet the demand for quick production of war materials for our allies, much of which was made in automobile factories. After the declaration of war by this country, the withdrawal of men for military purposes became a serious factor. The

*Where monthly figures are used for the sake of comparison with the previous year they are reduced to the same basis as the reports of the previous year. Viz., the report of the number employed in July, 1917, when used for comparison with 1916, is that reported by the same 36 factories as reported in 1916.

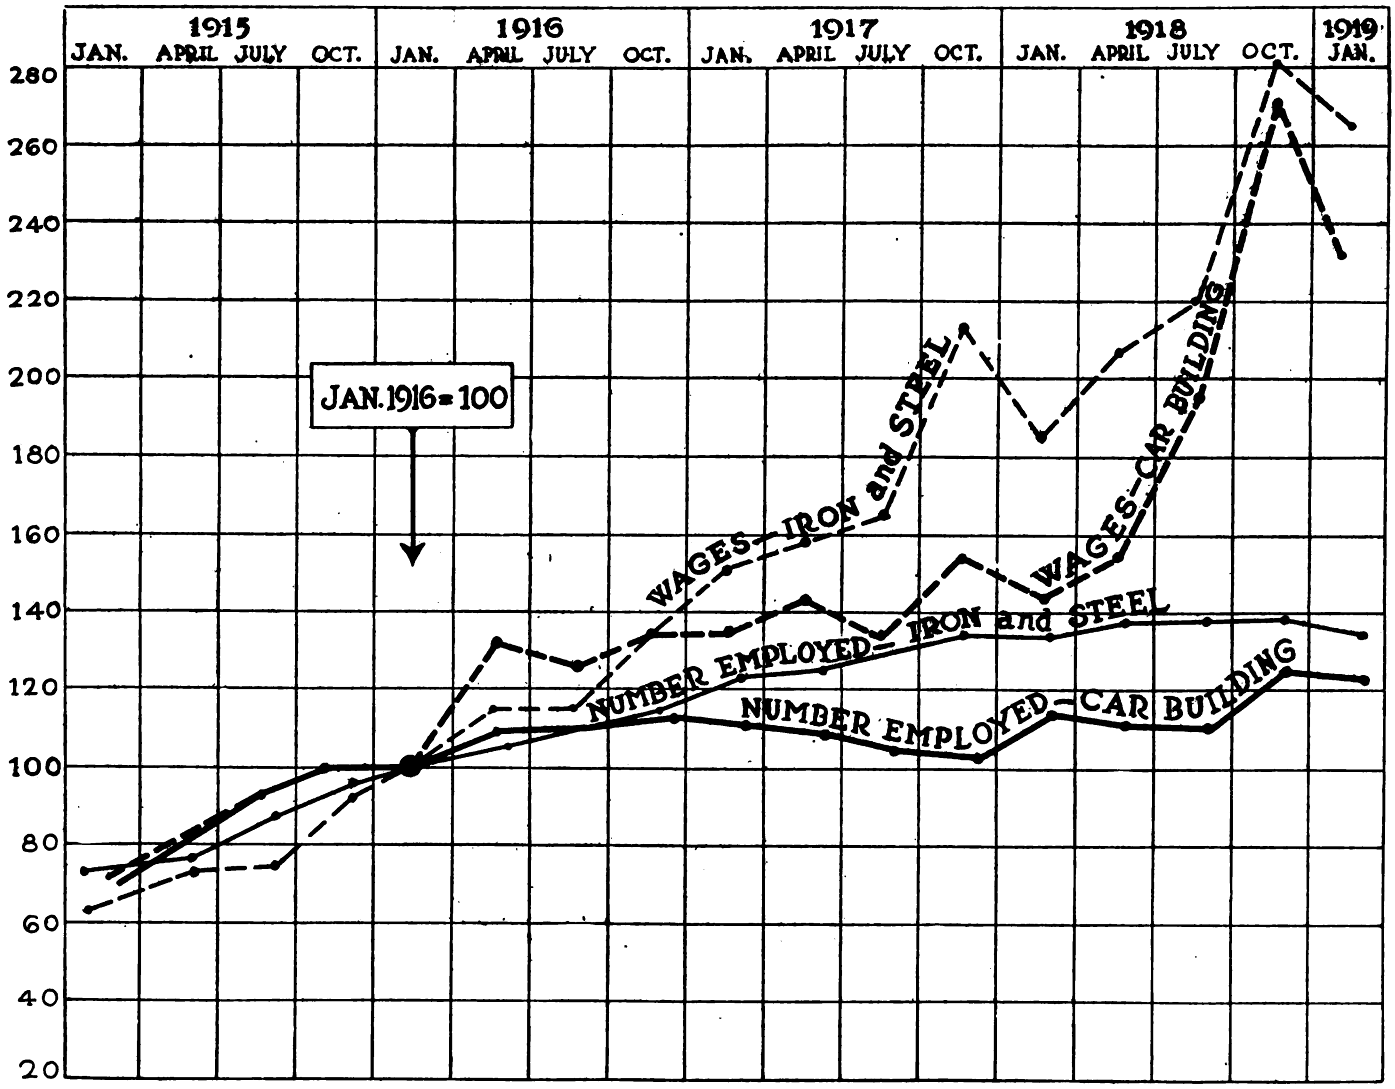

Chart 2—Relative number employed and wages paid in other large industries, based on figures for January, 1916, as 100 per cent

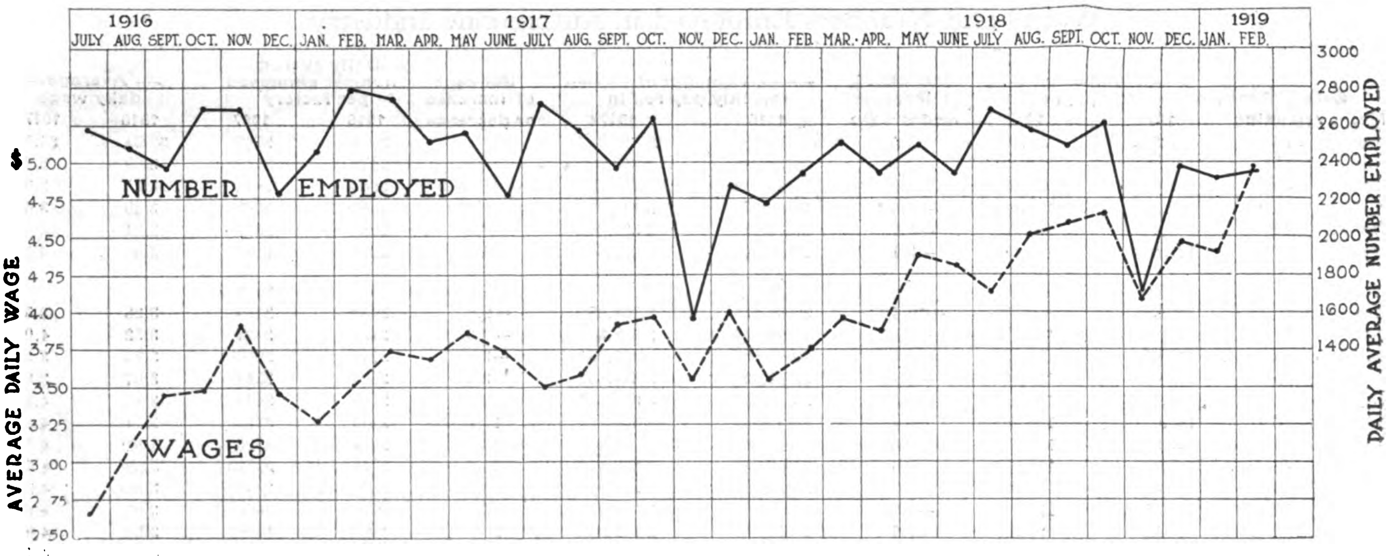

Chart 3—Showing the average daily number employed and wages in the automobile industry

high cost of living later became a contributory factor, but usually the demand for men in the automobile factories kept the wage increase in the industry ahead of the cost of living increase.

There is a close relation between the numbers employed in the automobile industry and in the kindred iron and steel and car building industries, as shown in Chart 2. In all of these industries the wage scale increased considerably more than the number employed, which usually is an indication of the wage increase.

Increased prices for passenger cars have apparently had no serious effect upon the sales, as production increased constantly and in even greater degree than the selling prices up to 1918 when government control limited the output.

Seasons Maintained

That the numbers employed and the wage scales rise and fall simultaneously in normal times is indicated by the curves from November, 1915, until November, 1917, following which time the effect of the war became noticeable and the wage scale of the automobile industry increased while the numbers employed decreased (see Chart 1). Shortly after, in January, 1918, the influence of the war on production and working organizations was marked with a decline.

Prices of steel and iron rose to unprecedented heights in 1917, increasing more than 300 per cent. A reduction to an increase of 150 per cent above pre-war prices was effected in 1918 when the government exercised its price control. Crude rubber, although fluctuating during the past four years, has maintained a fairly stable price level.

It is particularly interesting to note (Chart 3) that the wages from July, 1916, to February, 1918, rise and fall in practically the same months as the wages from July, 1917, to February, 1919, although the latter scale is approximately 50 per cent higher, indicating that some such influences as inventory or selling seasons or production seasons have a slight effect. Similarly the size of the working organizations rises and falls in similar months for different years. Apparently the war had very little influence on those factors which caused the slight increases and decreases that mark the different months on the chart as it will be noted, the number employed from July, 1916, to February, 1918, had decreases in December, 1916; June, 1917, and November, 1917, which were again displayed in the curve for the period July, 1917, to February, 1919.

The increased price of passenger cars is apparently due equally to the increased prices of steel and iron and the growing wage scale.

In the table showing the wages and numbers employed in the automobile industry it will be noted that wage increases have been as high as 33.4 per cent for one year while decreases have never totaled more than 6 per cent. Working organizations have increased as much as 9.7 per cent when in November, 1918, they increased to 87,536 from 79,831 employed in the same month of the preceding year. The greatest wage increase was recorded in July, 1917, when the pay roll of thirty-six manufacturers totaled $2,154,737 as compared with $1,615,257 in the same factories for July, 1916. A considerable increase was also noted in February, 1919, when the pay roll totaled $3,240,057 as compared with $2,445,176 for February, 1918, an increase of 32.5 per cent.

A Review of the Motor-Fuel Situation

Limitations and Possibilities of Different Fuel Sources—Interrelations of Engine and Fuel Development—Comments on the Essentials of a Research Organization

By Joseph E. Pogue*

THE rapid growth of the automotive industry has so increased the demand for motor-fuel that the ability of the fuel supply to keep pace has come into question. As a stringency in fuel supply will prove a retarding factor in the expansion of the automotive industry, the subject is a vital one not only to automotive manufacturers, but to the general public as well. A review of the motor-fuel situation as it stands in 1919 is, therefore, timely, for only by widespread appreciation of the nature of the fuel problem and especially of the steps that may be taken in solution can the most favorable outcome be assured.

THE PETROLEUM SITUATION

Crude petroleum to the extent of approximately a third of a billion barrels is mined annually in the United States. Most of this quantity is refined to produce gasoline, kerosene, fuel oil, lubricating oil, and various by-products. The relative production of these products in 1918 is shown in Fig. 1.

Gasoline, of course, is the predominant motor-fuel in use in this country; kerosene is coming into prominence as a motor-fuel, although a small part only of the output as yet finds such application; fuel oil, which bulks larger than gasoline and kerosene combined, is mostly employed for firing boilers, although a trifling quantity is used in Diesel engines and a small fraction is converted into gasoline through processes of pressure distillation known as "cracking."

The Joint-Product Character of Gasoline.—Gasoline is not an independent product, free to respond singly to motor-fuel demands, but is intimately tied up with the production of other constituents of crude petroleum, especially kerosene and fuel oil. In consequence, the price and supply of gasoline are influenced by market conditions holding for kerosene and fuel oil.

Before the vogue of the internal combustion engine, gasoline was a by-product of little value turned out in connection with the manufacture of kerosene, but the rapid upgrowth of the light motor has brought gasoline into more urgent demand than either kerosene or fuel oil, with a resultant price discrepancy between the three (see Fig. 2). Means, however, are now developing for converting kerosene and fuel oil into gasoline, as well as for using them directly in motors, and in proportion as the motor-fuel demand encroaches upon these cheaper products their price advantages over gasoline will tend to disappear.

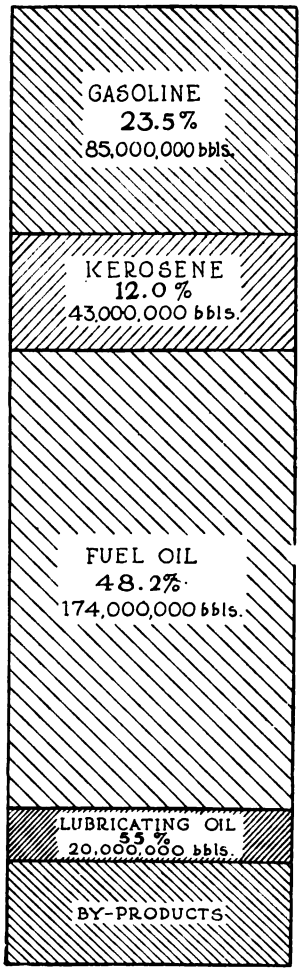

Fig. 1—The production of petroleum products in the United States during 1918

The close interplay between gasoline, kerosene, and fuel oil, arising from their production in common from a single raw material and their (as yet limited) interchangeability, is a factor of great significance which should be held clearly in mind in viewing the motor-fuel situation.

Era of Surplus Gasoline.—Until recently, crude petroleum was mined in gross excess of the quantity necessary to provide an ample supply of gasoline. Much gasoline in consequence was unrecovered from the crude petroleum brought into use. This gasoline represented "slack" in the situation (see Fig. 3). During this period, expansion in gasoline output was readily effected merely by subjecting a growing share of the crude output to refining.

Even though the rate of increase in gasoline production has for some ten years exceeded the rate of increase in production of crude petroleum, no stress was felt until the gasoline "slack" began to run out around 1917. Then the burden shifted to more rigorous means for sustaining the supply.

The Era of Tightening Gasoline Supply.—At present practically all the easy-to-extract gasoline is removed from the crude petroleum mined, and the motor-fuel demand is not filled by the quantity obtained. A growing discrepancy is covered by cracking fuel oil into gasoline, by lowering the volatility of gasoline which permits a larger percentage (at the expense of kerosene) to be extracted, and by gathering the gasoline suspended in natural gas. These economic expedients are recent developments, and are being called more and more into play by the rapidly expanding demand for gasoline. In the absence of conspicuous gasoline "slack" within the crude supply, the expansion in output of crude petroleum has ceased to be adequate to accommodate the situation.

Supply of Crude Petroleum Limited.—Not only is the production of crude petroleum failing to keep pace with the demand for motor-fuel, thus already forcing into play other expedients for expanding the supply, but also the unmined supply of petroleum has a physical limit which is rap-

*Division of Mineral Technology, U. S. National Museum. Formerly of the Oil Division, U. S. Fuel Administration.

idly being approached. The U. S. Geological Survey in early 1919 estimated, on the basis of extensive engineering data, that the available petroleum still underground in the United States approximates 7,000,000,000 barrels.

In view of the large and rapidly increasing annual draft upon this reserve, the supply seems startlingly inadequate to sustain the motor-fuel situation for any satisfactory period of time. Moreover, it is well known, because of the greater extent of drilling necessary, that petroleum may be mined only at increasing cost and with increasing difficulty as the resource is depleted. It is already a common belief among petroleum engineers that the oil output of the United States has practically reached its maximum.

The recent interest on the part of the oil industry in acquiring reserves of petroleum in Mexico and South America is but the business reflex to this point of view. But even with the most optimistic assumptions on behalf of contributions from foreign countries, it can scarcely be hoped that the petroleum reserve available to the automotive industry of this country will be found to exceed twice the quantity now in sight.

Supplementary Gasoline from Natural Gas.—At present a highly volatile gasoline is extracted from natural gas in many parts of the country and blended with petroleum distillates too heavy alone to be marketed as gasoline. In this way, commercial gasoline in quantity aggregating about 10 per cent of the total supply is manufactured. The production cost of such gasoline is low and the growth of this industry has been rapid in the past few years. The contribution of this by-product source, however, is limited as to the future, since natural gas is a waning industry and gasoline is already being extracted from roughly half of the supply.

Cracked Gasoline from Fuel Oil.—Fuel oil, the petroleum product turned out in greatest bulk and selling around a quarter to a fifth the price of gasoline (see Fig. 2), is the source of a growing quantity of gasoline. By special methods of distillation, certain qualities of fuel oil are transformed or "cracked" into a grade of gasoline that is mixed with straight refinery gasoline

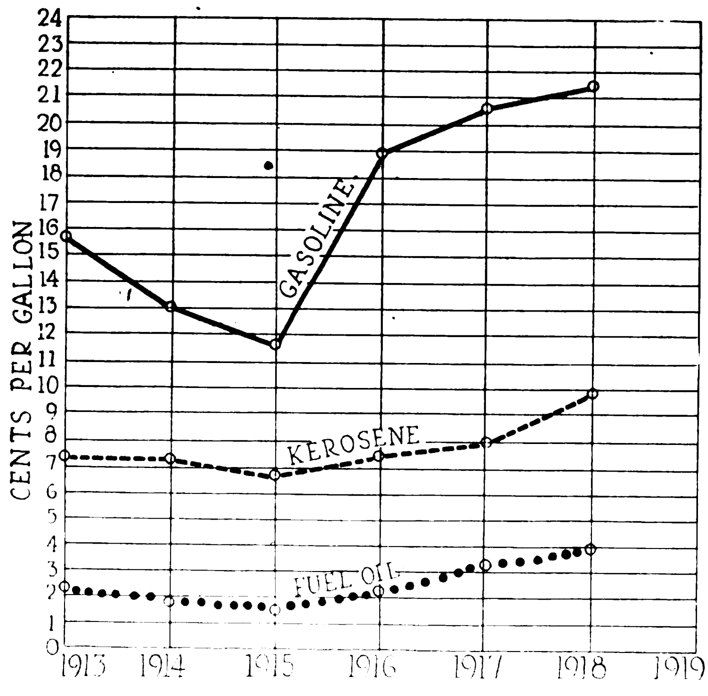

Fig. 2—The average wholesale price of gasoline, kerosene and fuel oil in 1913-1918. Data from Oil Division, U. S. Fuel Administration and Price Section, Bureau of Planning and Statistics, War Industries Board

and contributes by so much to the total supply. Information is wanting as to the exact contribution made by cracked gasoline, as the cracking operation is often an integral part of the ordinary refining process, and the records are not separately available.

Theoretically, the supply of gasoline can be doubled, or even trebled, from the same quantity of crude; but practically, the development and expansion of cracking processes are slow and it is estimated that it would require something like ten years for cracking to double the percentage of gasoline obtainable from crude over the average of 23 per cent now extracted.

In the meantime, other insistent demands bearing down upon fuel oil may be expected to lessen the price interval between fuel oil and gasoline, which is now the chief economic motive for the process. With engines adopted only to volatile gasoline, the automotive industry is now almost wholly dependent upon the competency of cracking to expand the fuel supply. Whether cracking can meet the issue fully without an undue increase in the price of gasoline (which, in fact, would not be meeting the issue) is open to question.

Additional Motor-Fuel by Lowering the Volatility of Gasoline.—It is common notoriety that gasoline during the past few years, especially during the past twelve months, has been becoming heavier and less volatile in quality. In this way, the total supply of gasoline has been increased at the expense of the lighter fractions of "kerosene" which went the way of motor-fuel instead of illuminating oil. This outcome is thought to be the normal economic response to a growing demand that the increases in crude production and the increments from natural gas and cracked fuel oils were unable to meet unaided. At any rate, lowering volatility is in actual progress and thus far the tide has not been stemmed, although the tendency has been widely frowned upon and excoriated.

Kerosene as Motor-Fuel.—Kerosene which sells now for about half the price of gasoline (see Fig. 2) is available for use as a motor-fuel (a) either directly as such, (b) after cracking into gasoline, or (c) through addition to the gasoline supply, which is thereby decreased in volatility.

There is a growing tendency, especially in the tractor industry, to use kerosene directly as a motor-fuel, but thus far its use in the gasoline engine cannot be said to have given generally satisfactory results. Cracking processes are under development which employ kerosene as their raw material, but the commercial practicability of such processes remain largely to be established; up to the present certain grades of fuel oil represent the dominant raw material from which cracked gasoline is produced.

The indirect use of kerosene through incorporation into the gasoline supply has already been adverted to; this use has already appreciably reduced the output of kerosene proper, but the engine in current use interposes a barrier to a practical extension of this expedient to embrace the entire kerosene cut.

Kerosene commands a lower price than gasoline merely because it cannot be so readily used for motor-fuel purposes. As soon as it assumes a parity in use, it may be expected to attain an equality in price.

Fuel Oil as Motor-Fuel.—Fuel oil is available as motor-fuel (a) directly in the heavy-oil engine of the Diesel or semi-Diesel types, (b) indirectly through the avenue of cracking into gasoline, and (c) directly in the current type of engine through the medium of gasification by means of heat.

As fuel oil is now almost exclusively used for steam-raising and gas manufacture—purposes for which coal would suffice—virtually the entire supply can be eco-

nomically captured by the automotive demand. Fuel oil is due for a rapid diversion to transportation purposes, and competition will rapidly develop between cracking, on the one hand, and a direct use, either in heavy-oil engines or upon gasification in light motors, on the other.

It remains to be seen whether this competition will result in a retardation in the development of cracking technique, the direct uses winning out; or whether cracking will prove competent to augment progressively the gasoline supply, the field of direct uses being accordingly narrowed by this counter demand. Upon the outcome will depend the course that engine development in the truck and tractor industries should take—whether the goal should be the heavy-oil engine, gasification apparatus, or a continuation of the present type of motor.

The whole matter, from the automotive standpoint, is complicated by the tremendous prospective upgrowth in the use of the marine motor burning fuel oil—a development that will encroach more and more upon the fuel oil supply at the same time that fuel oil is coming to be needed by automotive agencies on land.

SUPPLEMENTARY RESOURCES OF NON-PETROLEUM ORIGIN

With the tightening up of the gasoline situation, with its attendant problems as to the competency of cracking to maintain adequate increases in supply versus engine adaptation in the direction of accommodating the heavy fractions of petroleum distillation, there come into view a number of supplementary fuel resources such as benzol, alcohol, and shale-oil distillate, seeking a motor-fuel rôle. These fuels, or at least the first two, are now beginning to come upon the market, and although they were unable to compete with gasoline during the era of gasoline surplus, they now have possibilities of development as opposed to supplemental resources of petroleum origin, such as kerosene, fuel oil, and cracked gasoline. Whether these supplements can edge into use before crude petroleum is yielding up its full quota of motor-fuel values is an important question, the answer to which is contingent, in part, upon the fuel policy of the automotive industry.

Benzol as a Motor-Fuel.—Benzol is a light oil produced in commercial quantities along with coke, gas, ammonia, and tar, when bituminous coal is subjected to distillation in the by-product coke oven. The average yield is about 2½ gallons of benzol per ton of coal and roughly 1-12 of the bituminous coal mined in the United States is treated in this way.

The country's output of benzol has increased materially during the war, owing to the demand for this product in connection with the manufacture of explosives, resulting in a surplus of benzol now which must find an outlet in the form of motor-fuel. Increases over the present supply of benzol, however, are contingent upon the rate of progress in the by-product utilization of coal, which in turn is dependent upon the rapidity with which the beehive coke oven is replaced by the by-product oven in the coke industry, and the course of progress in the gas industry in the direction of supplying the fuel needs of communities under by-product practice.

At best, the benzol available for motor-fuel use must represent only a small fraction of the motor-fuel demand; but at the same time the quantity available must be reckoned with.

Benzol is a satisfactory fuel in the present type of engine, after a slight carburetor adjustment which is readily made. Fortunately it is miscible with gasoline, so that it may be used alone, mixed with gasoline, or alternating with gasoline. This feature greatly simplifies the problem of distribution.

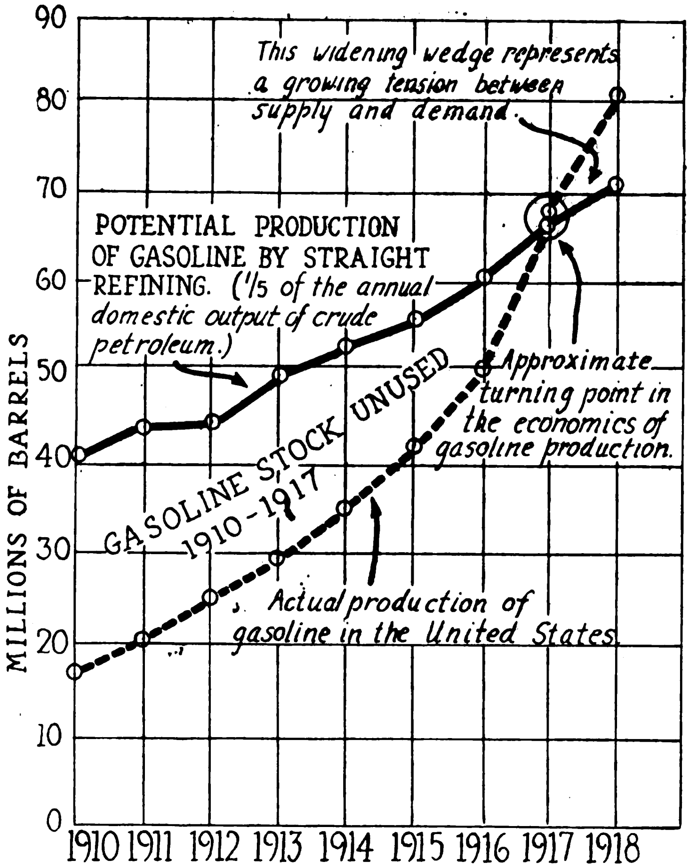

Fig. 3—Chart showing the tightening up of the gasoline supply in the United States. Data from Oil Division, U. S. Fuel Administration

Benzol is already coming on the market in small quantities in the eastern part of the country, selling at the same price as gasoline.

Alcohol as Motor-Fuel.—Alcohol stands apart from the fuels previously reviewed in the fact that it can be made from products of vegetable origin which are reproducable from year to year and therefore makes no drain on resources limited in quantity. As it constitutes a satisfactory fuel even in the present type of engine, and so far as raw materials are concerned can be manufactured in practically unlimited quantities, it offers a reassuring prospect in the face of a rapidly waning petroleum reserve.

Alcohol in composite form, mixed with benzol, kerosene, and other materials, has already come on the eastern market in small quantities; and manufacturers of industrial alcohol are making efforts to build up a motor-fuel demand for this substance.

The future of industrial alcohol as a motor-fuel remains to be seen. Thus far it has been unable to compete with gasoline, which was to be expected during the era of "easy" gasoline, especially as the cost of production, in the United States at least, has prevented a selling price in competition with gasoline.

With increasing facility in production, especially if the price of gasoline goes up a few cents, alcohol may be expected to assume increasing prominence; and it is an open question as to whether alcohol may not come into widespread use more rapidly than shale-oil distillate, its rival supplementary resource.

The legal difficulties in the way of widespread alcohol utilization, however, are to be taken into account as a retarding factor; although the coming in of Prohibition will free capacious manufactories for the production of industrial distillation products in the place of beverages

and give further incentive for the development of industrial alcohol.

Alcohol, therefore, must presumably sooner or later be reckoned with as a motor-fuel. The progress of alcohol, however, will depend not so much upon its own merits as upon its status in regard to the range of motor-fuels likewise undergoing development and the extent to which its upgrowth will fit into the general situation. These relationships have scarcely as yet been sufficiently investigated to permit of more definite statement in advance.

Shale-Oil Distillate as Motor-Fuel.—The occurrence in many parts of the country, especially in Colorado, Utah, and Wyoming, of immense areas of black shales, capable of yielding upon distillation appreciable quantities of an oil analogous to petroleum, has attracted considerable attention of late and offers a prospective source of motor-fuel. Oil-shale, indeed, is generally looked upon as the logical successor to petroleum, which will come into commercial development as soon as the richer petroleum resource needs a supplement.

Shale-oil cannot be produced as cheaply as petroleum at the present price level of the latter, although it is expected by many that moderate price advances over the present scale may bring shale-oil on a parity.

Considerable preliminary developments have already taken place over the past few years in Colorado and Utah particularly, but the progress of the new industry has been slow. At best, even granted a distinct need for output, the development of a large production of shale-oil must be a matter of many years, because of the extensive mining operations and large distillation plants that must come into existence as a preliminary.

Shale-oil will probably be able to yield a range of products roughly analogous to those extracted from petroleum, which is a very fortunate circumstance for the automotive industry, since engines developed for petroleum products will presumably prove suitable for shale-oil products. On the other hand, there is danger of a hiatus in supply, should petroleum output fall off more rapidly than shale-oil output develops; although a rapid development of fuel alcohol may stand ready to fill in the gap.

All these uncertainties, however, make it the more imperative that the automotive industry should adopt a fuel policy broad enough to care for all contingencies.

Composite Fuels.—Heretofore, automotive transportation has employed single fuels, chiefly gasoline. With the approach of supplementary fuels, and with progress in fuel research, the matter of mixed or composite fuels is assuming considerable interest. If it becomes necessary for the motor-fuel demand to be met by two or more fuels of diverse sources, the question of distribution will assume added importance, as to whether those fuels may be more advantageously marketed separately or as a blend.

It may turn out that a virtue can be made of a necessity, so to speak; for initial researches on mixed fuels have already gone to show that certain admixture may yield more favorable results than the components in severalty. Indeed, it is thought by some that results of almost revolutionary significance may be attained by intensive research in this direction following the trend of the economic situation in respect to motor-fuel production.

Up to the present, the field of composite fuels has been beclouded by a number of fakes and half-baked developments, to which an undue amount of publicity has been given. The industry will have to continue to be on its guard against falsifications in a field so little known and with possibilities so unsounded.

Significance of New Fuels Relative.—Since automotive transportation has developed and become standardized on the basis of gasoline, the significance of the various fuels coming into sight to supplement the gasoline supply does not depend upon the individual merits of the fuels so much as upon their capacity to enmesh with the existing situation.

A study of individual fuels, therefore, will prove misleading if not accompanied by an appraisal of the relationship that each bears not only to gasoline but to all other fuels that have potential motor use. This is one of the features which renders the motor-fuel problem

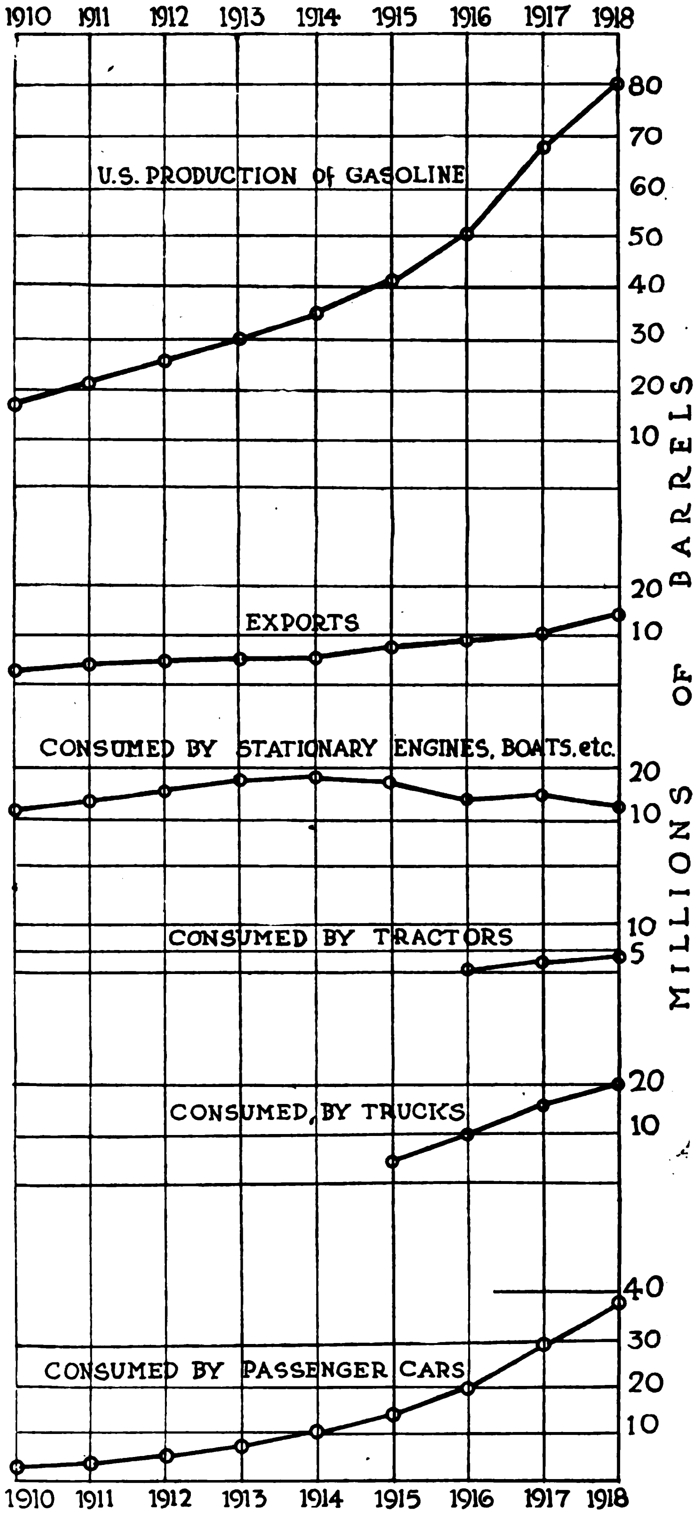

Fig. 4—Chart showing the rate of increase and character of the motor-fuel demand during 1910-1918. Data from Bureau of Oil Conservation, Oil Division, U. S. Fuel Administration

so intricate and so elusive if viewed with its various parts dissociated. It cannot be too strongly emphasized that the merits of any single factor in the situation, whether it be a process such as cracking, a new fuel undergoing development such as benzol or alcohol, a fuel in the offing such as shale-oil distillate or new types of mixed fuels, cannot be evalued unless cross-referenced with respect to all counter developments falling under its sphere of influence.

Such a condition renders a discussion of the situation peculiarly difficult, since the exigencies of language require that each topic be discussed separately, and all the due qualifications and cross-currents cannot be introduced without a fatal sacrifice of clearness and brevity. In visualizing the trend of the motor-fuel situation, therefore, the reader must hold in mind that the advance is not comprised of elements developing in parallel manner, but is more like a jostling crowd of components, each affected by the recurring impacts of all the others.

EVOLUTION OF THE MOTOR-FUEL SITUATION

If we view broadly the development of the automotive apparatus from a fuel standpoint, there appears to be an evolutionary trend behind the matter, with a bearing of considerable significance upon the issue under consideration.

Era of Engine Independence.—The era of gasoline surplus, when gasoline remained unextracted from a significant share of the output of crude petroleum, may also be termed the era of engine independence. The expansion in motor-fuel demand was then met by running a larger share of the crude petroleum through refineries, and the gasoline supply was maintained without sufficient change in quality to dictate adaptations in engine design. During that time, engine progress lay largely in the direction of refinements of quality—flexibility, power, convenience, etc. Fuel was standardized—a volatile gasoline—and the engine was independent of other fuel considerations.

Era of Superficial Concessions to Fuel.—During the past few years, a tightening up in the gasoline supply has become apparent, and in spite of various expedients for maintaining the gasoline of earlier days, a notable change in quality has come into evidence.

Gasoline has been getting heavier, less volatile, embracing an increasing quantity of material formerly produced as kerosene. This progressive change in gasoline quality is especially noticeable in winter, because of difficulties in starting engines, and during the past two winters in particular troubles on this score have passed the stage of inconvenience. So long as both fuel and engine remained standardized, all was well.

Now the fuel is undergoing de-standardization, so to speak, and the engine, built to use high-volatile gasoline, is forced to use low-volatile gasoline. Already, the engine has recognized this maladjustment, as indicated by superficial concessions to this state of affairs, as by preheaters, hot-spots, and the like, and by the upgrowth of a host of so-called fuel economy devices. The engine is now passing through an era of superficial concessions to the fuel situation.

Future Relation of Engine and Fuel.—Unless the present trend of motor-fuel reverses itself, the automotive industry will have to cope with a fuel growing progressively less specialized, or else with a diverging range of fuels, which comes to the same effect. The automotive industry, theoretically, can stop the change now taking place in fuel by holding fast to the present engine in detail, but this procedure will so limit the supply and increase the price of fuel that in practice the engine will have to give way.

It is concluded, therefore, that an era is arriving when the engine will have to make rather radical concessions to fuel, as a relief to a strained situation; and the problem before the automotive industry is: First, to recognize this situation; and second, to establish means for making these concessions with the maximum easement to the supply and price of fuel. Anything short of this will mean just so much of a detriment to the growth of automotive transportation.

A view of the rapidly increasing demand for motor-fuel, as shown graphically in Fig. 4, with reference to the limitating factors in supply as already noted, will emphasize the likelihood of conditions arising that will influence engine design.

Realization of a Motor-Fuel Problem.—The inevitable concern of the automotive industry in the motor-fuel situation is just coming to be appreciated. A year ago it was quite generally felt that fuel was a thing apart from automotive manufacture. Now the fuel situation is a live issue in the automotive industry.

The rise of a fuel problem, however, was not entirely unanticipated. For years the U. S. Geological Survey and the U. S. Bureau of Mines have pointed out the limited size of the petroleum resource and the need for its conservation.

In 1918, the Bureau of Oil Conservation of the Oil Division of the Fuel Administration made a special study of the motor-fuel situation and urged both upon the National Automobile Chamber of Commerce and the Society of Automotive Engineers that the matter be brought effectively to the attention of the automotive industry.

At the winter meeting of the Society of Automotive Engineers on Feb. 5, 1919, a morning was devoted to a fuel session, at which time a number of authoritative papers were presented, which served to outline the situation and call attention to the issue.[1] Following this meeting there has been a general agitation of the matter, and the topic of motor-fuel is now prominently before the automotive interests.

As a specific outcome of the meeting, a fuel research committee was appointed by the Society of Automotive Engineers, and this committee is now formulating plans for the establishment of a research organization charged with the duty of handling the fuel problem in behalf of the automotive industry.

SOLUTION OF THE MOTOR-FUEL ISSUE

Although the existence of a fuel problem is already generally appreciated, and preliminary steps have already been taken toward attacking the issue, there is danger that the true nature of the problem will not be apprehended and consequently a false start may be made.

While the problem is exceedingly complex when all its details are taken into consideration, the fundamentals appear to be sufficiently clear if the matter is logically analyzed. For example: Accepting the existence of a tightening-up tendency in the fuel supply as an obvious fact, there are two avenues of relief—increasing the efficiency of fuel utilization and enlarging the fuel supply itself. The first issue is a more direct matter than the second and may be more concretely handled, if concerted

[1]These papers were planned to give an authoritative expression of each important phase of the fuel problem, as follows:
1. The Unmined Supply of Petroleum in the United States, by David White, U. S. Geological Survey.
2. Mexico as a Source of Petroleum and Its Products, by E. DeGolyer, Consulting Geologist.
3. The Status of Refinery Practice in the United States, by E. W. Dean, U. S. Bureau of Mines.
4. The Status of Engine Efficiency in the United States, by H. C. Dickinson, U. S. Bureau of Standards.
5. An Interpretation of the Engine-fuel Situation, by J. E. Pogue, U. S. Fuel Administration.
6. More Efficient Utilization of Fuel, by C. F. Kettering, President of the S. A. E.

engineering effort and business policy is brought to bear intensively upon it.

In regard to increasing the fuel supply directly, however, the issue takes on a more intangible and elusive aspect. The curve of oil production is lagging behind the curve of motor-fuel demand, and consequently improved technology and supplementary resources must come into action if an unbroken advance is to be maintained.

But inadequate study has yet been brought to bear upon the relationship that the various fuels undergoing development hold to the fuel (gasoline) in current use, and therefore, to put the matter bluntly, relatively nothing is known of the real situation as it is shaping up. In other words, the problem has transgressed the bounds of the conventional methods of study and research heretofore employed; and unless new means are brought to bear upon the problem, no hope of a solution should be entertained.

Need for Scientific Control.—What is needed is an agency, representative of the automotive industry, competent to bring engine development into harmonious adjustment with fuel developments. This adjustment, of course, will ultimately be attained under the give and take of competition, but such an adjustment will prove slow and wasteful, and the industry, in the meantime, will be subject to retardation in event of fuel shortage. Instead of awaiting such an outcome, with its attendant vicissitudes, the automotive industry can take the matter in hand now and, by applying scientific method to the issue, insure itself against the evil effects of a period of fuel stress.

Means for Administering Scientific Control.—The fuel research organization now (June, 1919) undergoing formation is the obvious agency upon which the industry must depend for a solution of the fuel problem. Upon the vision and ability of this organization the success of the whole matter turns. It is of the utmost importance, therefore, that this organization be projected commensurate with the character and importance of the problem it is designed to solve.

The Functions of a Fuel Research Organization.—The fuel problem is not one which laboratory research alone can solve. The fuel situation must be explored and harmonious fuel policies must be developed, in addition to the work of research upon fuels and engines.

A fuel research organization, therefore, to be adequate, must accommodate three functions: economic analysis, to determine the course of fuel developments in relation to engine design; research, to build up the technology requisite to advance in fuel efficiency and fuel production; and industrial co-ordination, to insure an aggregate of fuel policies in adjustment with the needs of the fuel situation.[1] Only through an adequate organization, functioning in this three-fold manner, can the requisite efforts toward increasing thermal efficiency and enlarging the fuel supply be put forward by the automotive industry.

It cannot be emphasized too strongly that an ample supply of fuel depends not only upon the efficiency obtained in the engine from the fuel actually used, but also upon the efficiency attained in the realm of fuel production, which is contingent, in part, upon the requirements of the engine-type. It is the peculiar nature of the fuel problem to embrace the possibility of contributing to an easement of fuel supply in these two directions.

Difficulties in the Way of Progress.—There is a grave danger, at the present stage of affairs, that the true nature of the fuel problem will not be generally enough apprehended, and that a research organization too narrowly conceived to meet the issue will be established. This danger arises from the fact that a limited and narrow conception of the term "research" prevails, as being a matter entirely of material, laboratory investigations; while at the same time there exists a general tendency to overlook the fact that the fuel problem is primarily an *economic issue*, of which technology is only one factor.

Impossibility of Finding a Ready-Made Solution.—There seems to be a general feeling on the part of many in the automotive industry that a definite program for meeting the motor-fuel issue ought to be forthcoming. The point of view of the industry may perhaps be summarized in four questions.[2]

1. Are the gasoline producing companies doing all they can to produce the maximum motor-fuel from the available crude?
2. What must the automotive manufacturers do to obtain a greater percentage of efficiency from the fuel utilized?
3. What contemplated changes in fuel characteristics do the fuel producers expect will have to be made within the next five years?
4. What changes may this necessitate in the design of automotive apparatus?

It is felt by many that if answers to these questions could only be provided, the industry would then have a basis for action and could make definite progress.

In this light, however, it appears that an essential step in the problem—scientific exploration of the problem itself—is being quite universally overlooked. In the writer's opinion, no individual or organization in the country knows the answers to these questions. The answers have not been worked out. There has, indeed, been no agency engaged in working them out. If answers are necessary as a preliminary to action, the step immediately ahead is to establish an agency competent to bring adequate and rigorous scientific study to bear on the matter and to work out the answers.

In short, there appear to be three stages in the issue: First, the recognition that there is a fuel problem of concern to the automotive industry; second, the establishment of an organization for handling this problem under a true perception of the peculiar nature of the issue; and third, action. The first stage has been passed through; the danger now is that stage 2 will be too hastily attended to and that either the matter will lag for want of a convincing plan, or else lines of action will be followed leading off into impractical directions. The practical outcome, in fine, depends upon the type of motor-fuel research organization shortly to be established. This organization will either be equal to the occasion, or not; and if not, the immediate opportunity for progress will have been lost.

Confidence and Backing of the Automotive Industry Necessary.—It therefore behooves the automotive industry in its entirety to take the utmost interest and concern in the plans now under consideration for motor-fuel research. Without the financial support, confidence, and co-operation of the industry, a motor-fuel research organization cannot hope to go far. And conversely, without the existence of a central organization, built along broad lines and adequately equipped as to funds, personnel, and a true perception of the issue, the automotive industry will remain lacking in means for insuring its prosperity in the years immediately ahead.

[1] These three functions are elaborated in a paper, by the present writer, entitled "The motor-fuel problem," to be presented before the June Meeting of the Society of Automotive Engineers at Ottawa Beach and subsequently to be published in the Journal.

[2] This summary view was supplied the writer by David Beecroft in a letter of May 27, 1919

Automotive Export Problems During Post-War Period

The American Manufacturer Must Cultivate the Fields Opened to Him During Struggle to Offset Trade Lost by Allied Restriction — Figures of 1913 and 1918 Tell a Graphic Story

By Allen Sinsheimer

AMERICAN automotive manufacturers must completely readjust the world map of exports. There is little prospect of immediate renewal of the prewar trade with the Allies. There is every possibility that the Allies will constitute formidable competition for export automotive business. Consequently, American manufacturers will find it particularly important to work closely those fields they have cultivated since 1914; guard against loss of business by meeting competition, and develop all possible new fields in the Orient and elsewhere before England, France, Germany and Italy are able to expand.

These conclusions come as a result of a study of the automobile exports of the various nations in 1913, and the recent disclosures, by Allied officials at the Foreign Trade and U. S. Chamber of Commerce conventions. Statements by these officials show that the United States cannot expect a resumption of pre-war automobile business with the large European nations for several years.

England, France and Italy, it was asserted, must control their imports until they re-establish their exports. They find themselves, to-day, after four years of war, exporting in April, 1919, $28,423,563 worth of products to the United States in return for $336,848,859 worth

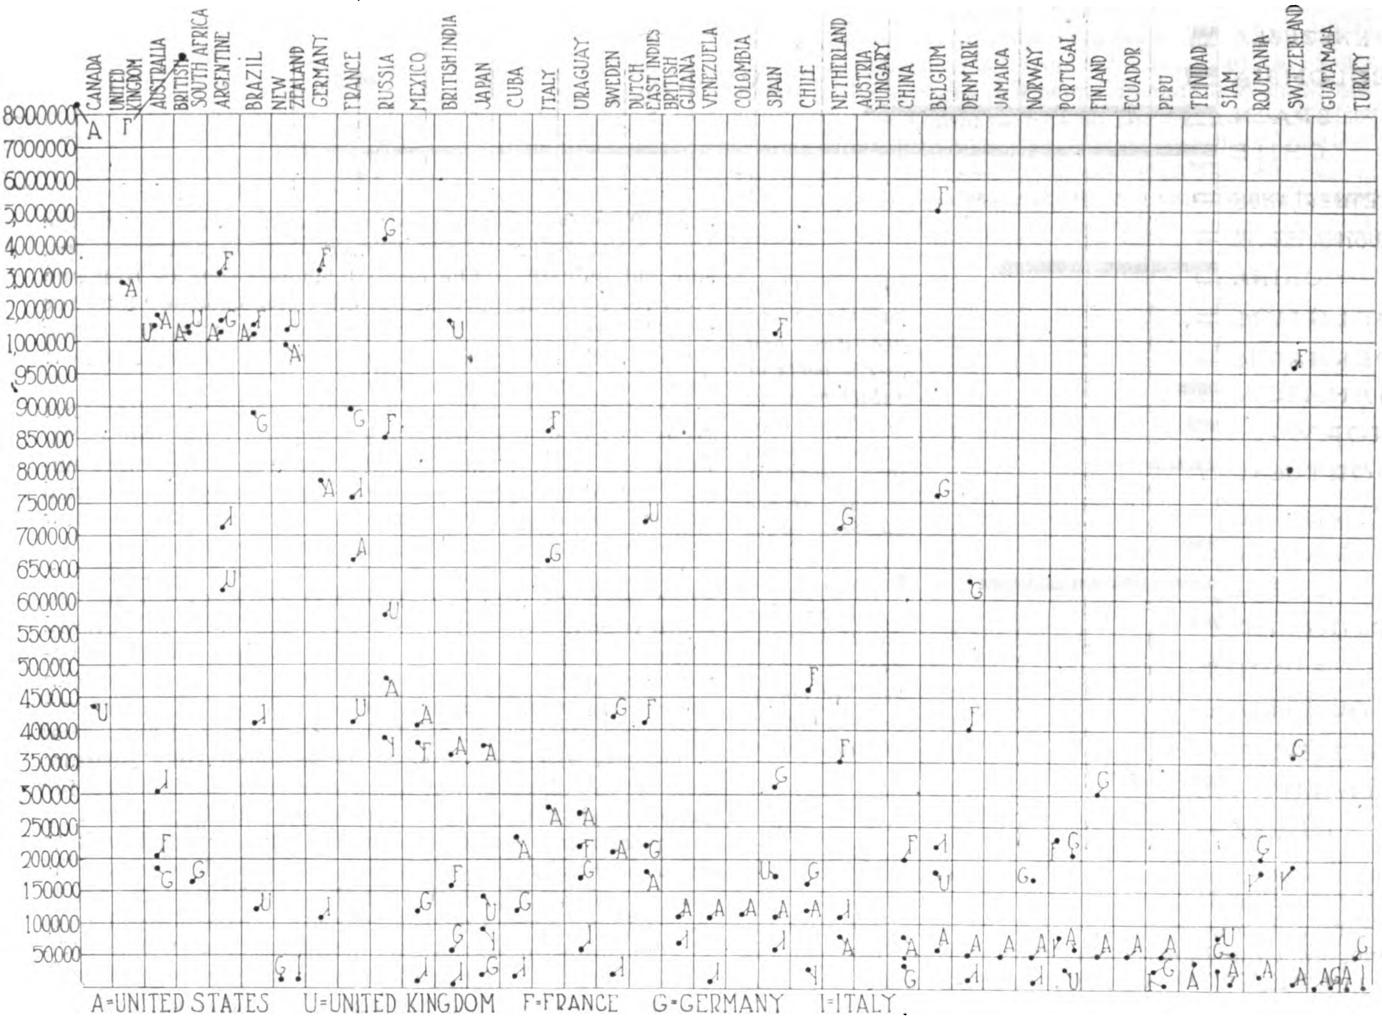

Chart 1—Showing the pre-war status of automobile shipments to the forty principal countries. France, Germany and the United Kingdom were very frequently larger exporters to certain countries than was the United States

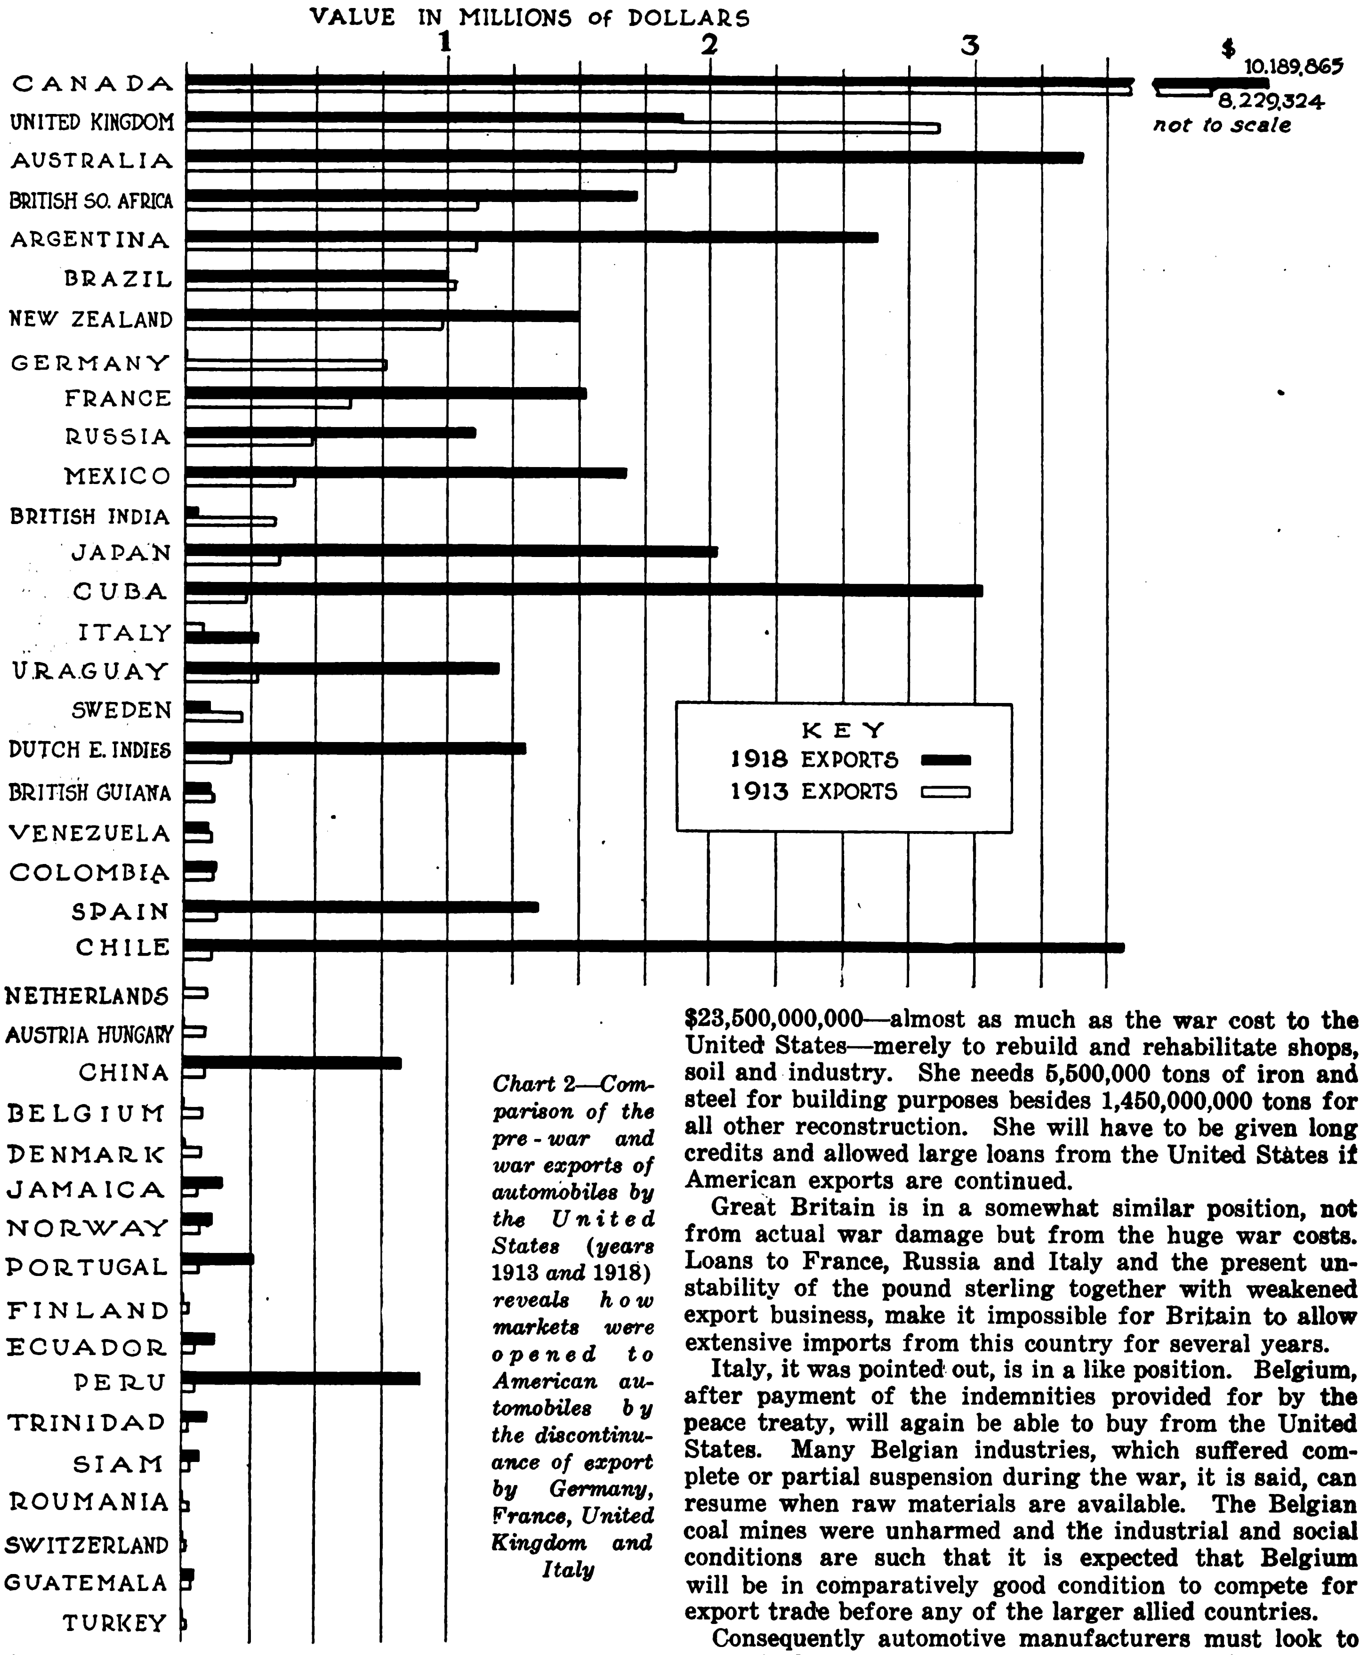

Chart 2—Comparison of the pre-war and war exports of automobiles by the United States (years 1913 and 1918) reveals how markets were opened to American automobiles by the discontinuance of export by Germany, France, United Kingdom and Italy

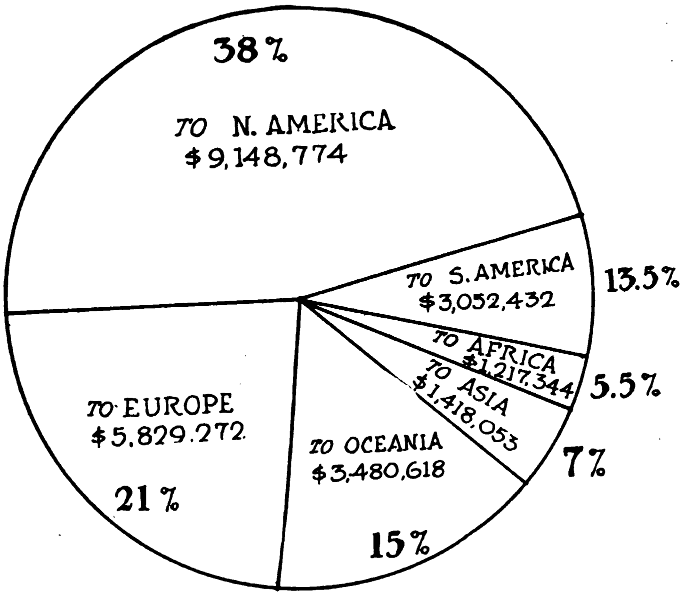
shipped from this country. This creates an unnatural trade balance and an unhealthy financial situation.

France, it was stated, is in such condition that it cannot even intelligently plan its future at present. It is short 222,000,000 tons of coal, has 250,000 miles of road to be repaired, needs 2500 locomotives and 35,000 freight cars, has $5,000,000,000 circulating in paper money against $772,000,000 gold deposit, will require $23,500,000,000—almost as much as the war cost to the United States—merely to rebuild and rehabilitate shops, soil and industry. She needs 5,500,000 tons of iron and steel for building purposes besides 1,450,000,000 tons for all other reconstruction. She will have to be given long credits and allowed large loans from the United States if American exports are continued.

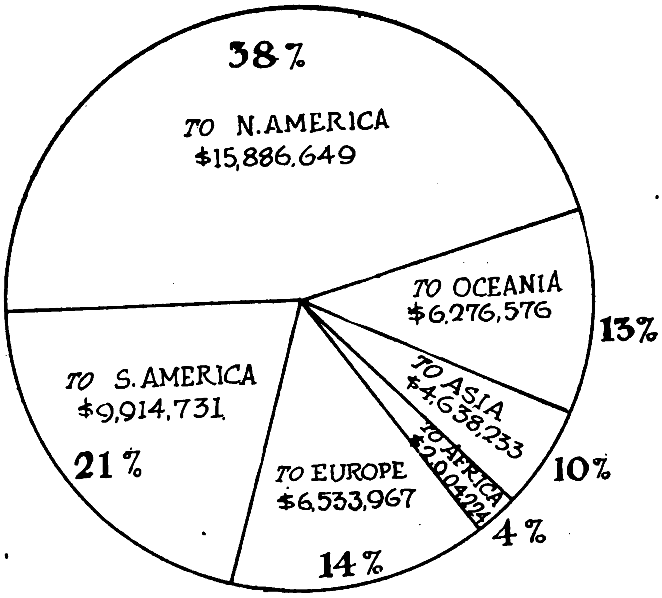
Great Britain is in a somewhat similar position, not from actual war damage but from the huge war costs. Loans to France, Russia and Italy and the present unstability of the pound sterling together with weakened export business, make it impossible for Britain to allow extensive imports from this country for several years.

Italy, it was pointed out, is in a like position. Belgium, after payment of the indemnities provided for by the peace treaty, will again be able to buy from the United States. Many Belgian industries, which suffered complete or partial suspension during the war, it is said, can resume when raw materials are available. The Belgian coal mines were unharmed and the industrial and social conditions are such that it is expected that Belgium will be in comparatively good condition to compete for export trade before any of the larger allied countries.

Consequently automotive manufacturers must look to other fields than the Allies for automotive business. The war completely upset the conditions of 1913. In Chart No. 2 it is shown that the export of automobiles by the United States increased from $24,275,793 in 1913 to $45,331,360 in 1918. The gain represents chiefly trade with countries which could no longer be supplied by Great Britain, Italy, France or Germany. As an example, our exports to Argentina increased from $1,181,735 in 1913



1913



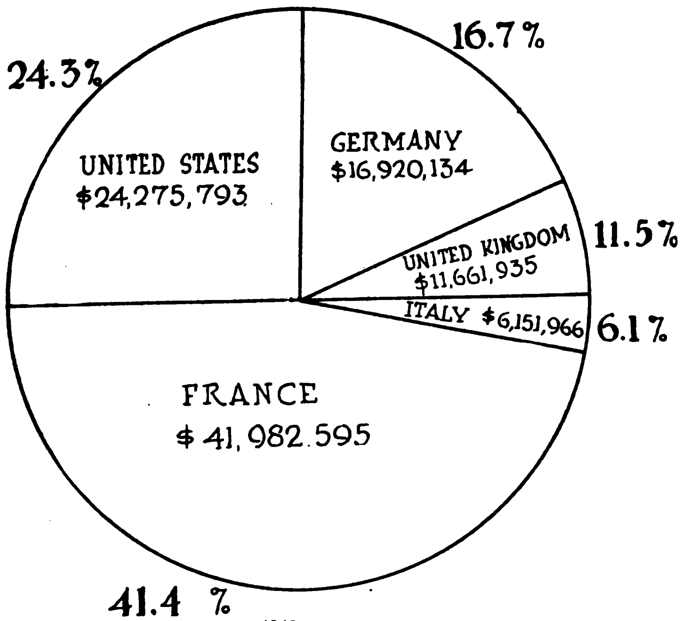
1918

Chart 3—Shipments of automobiles to North American countries were not affected by the war: South America assumed the position in 1918 that had been held by Europe in 1913, taking 21 per cent of the total exports, while Europe took but 14 per cent

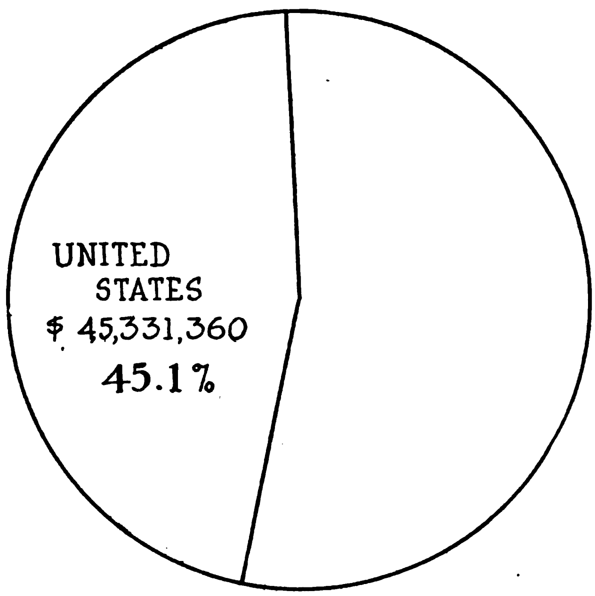
to $2,666,898 in 1918; to Uruguay from $273,253 to $1,-177,463; to Cuba from $242,686 to $3,029,813; to Chile from $109,982 to $3,576,511; to China from $90,459 to $830,997; to Spain from $127,621 to $1,346,826; to Dutch East Indies from $198,378 to $1,302,800, and to Peru from $55,646 to $913,669.

Prior to the war, as is shown by Chart No. 1, Chile purchased its automobiles chiefly from France, which shipped $606,926 worth of vehicles there in 1913; secondly from Germany, and thirdly from the United States. China made its greatest purchases from France; the Dutch East Indies from the United Kingdom, France second, Germany third, and the United States fourth. Argentina purchased chiefly from France, next from Germany and thirdly from the United States. The United Kingdom obtained its greatest imports from France and next from the United States.

By continents (chart 3) the exports of 1913, compared with 1918, show a steady increase of exports from the United States to North American countries. Exports to South America increased from 13.5 per cent to 21 per cent, while the exports to Europe decreased from 21 per cent to 14 per cent, indicating that the war had so shifted the exports to South America as to recompense American manufacturers for their losses in Europe. Africa, although increasing its exports, did not maintain a proportionate growth. Oceania, including Australia, the Philippine Islands and New Zealand, increased its purchases



1913



1918

Chart 4—The positions of the various automobile exporting nations in 1913 are clearly indicated in the above chart, which shows that France exported 41 per cent of the total as compared with 24.3 per cent shipped by the United States. With the entire world markets open, the United States shipped only $4,000,000 more of automobiles in 1918 than France exported in 1913

both in value and percentage, due to its inability to buy from Europe.

The problem consequently for the manufacturer is to develop export business among these countries to make up for losses caused by restrictions imposed by the Allies. Great Britain has temporarily allowed the American manufacturers to ship to that country 50 per cent of the number of cars sent there during the first seven months of 1913. This permission ends Sept. 1. It means that comparatively few automobiles will be exported, and those most likely will be used as demonstration and sales cars.

What will happen after Sept. 1 is problematical. It is not yet known whether Great Britain relaxed restrictions to meet the demand for passenger cars from this country temporarily, until the British manufacturers can get into production, or whether the relaxations will continue, but the wise manufacturers will base export plans on nations other than the United Kingdom. There is no prospect of business with France, which is maintaining a strict embargo, or Italy which cannot afford to buy automobiles abroad.

The most fertile fields appear to lie in South America,

the Orient, neutral countries of Europe and in British South Africa. The problem rests completely on whether or not American manufacturers will be able to hold the trade gained during the war. For instance, can the American exporter hold the business of Argentina, formerly held by France and Germany; or in Mexico which originally divided purchases between the United States, France, Germany and Italy; or Spain, which, prior to the war, purchased automobiles chiefly from France?

Spain, Portugal and the Scandinavian countries are prosperous and likely fields for American sales. The Scandinavian countries favor the United States. They disliked the strict censorship of Great Britain and the hardships imposed upon them by Germany during the war. Spain and Portugal, after four years' dealing with the United States, recognize and appreciate American merchandise, and the American manufacturer has an opening in these fields to-day, with a slight advantage over the Allies, who enjoy a better location, with more prompt supply facilities.

British South Africa, which prior to the war purchased its automobiles chiefly from Great Britain, and secondly from the United States, imported $1,706,136 worth of cars from this country last year, more automobiles than it purchased in any one year from Great Britain. To hold and increase this business will demand intensive effort from American manufacturers. Great Britain will make an earnest attempt to recover her export trade in British South Africa. It is a British colony, and has the advantage of cheap parcel-post rates from Great Britain.

The Latin-American countries demand special concentration and attention from Americans. It is in this field that the losses of exports to Europe can be balanced. Argentina, Brazil, Uruguay, Venezuela, Colombia, Chile, Ecuador and Peru are buying all of their automotive products from the United States. American manufacturers and Latin-American dealers and consumers have come

France's Car and Truck Exports

French automotive exports are recorded in pound weight instead of by units or values for individual countries. The following table thus permits of comparison by weights only. The year's total value in dollars is also given.

to a closer co-operation and understanding. South America is now so completely accustomed to American cars, so thoroughly prepared to make and adjust repairs and maintain American cars, that this business, which increased from $3,052,432, in 1913, to $9,914,731 in 1918, should be easily maintained and extended. There is little likelihood that Argentina, for example, will again turn to France or Germany for automobiles in preference to the United States product, if American manufacturers will study the habits and customs of the Argentine folk, and meet them with honest, fair, and intelligent business.

It is likely that Australia, which, prior to the war, purchased its automobiles in slightly greater quantities from the United States than from Great Britain, and which increased its purchases from $1,896,990, in 1913, to $3,410,557 in 1918, will continue to buy chiefly from this country unless the trend of the trade is changed by restrictions.

Similarly with New Zealand, which increased its purchases from the United States 50 per cent during the war. Before the war this was chiefly British trade. It is possible for American manufacturers to hold this gain.

Briefly, therefore, the problem confronting the American automobile exporter is to develop further those countries which turned to the United States during the war, to head off European competition, and particularly to study each individual market exhaustively, to learn its requirements so thoroughly that the foothold that Ameri-

Italy's Exports Are Classified as Follows:

Weight (Kilograms*)	Value		
	1908	1913	1915
Passenger cars:			
Under 500	$104,317	$10,461	$7,262
500-1,000	1,812,193	2,282,225	1,204,687
Over 1,000	3,533,182	3,859,280	4,165,313
Trucks:			
Under 1,000	1,544	28,477	334,865
1,000-3,000	44,030	369,927	5,765,180
Over 3,000	26,055	46,552	815,222

*Kilogram = 2.2406 lb.

can manufacturers have gained will be extended. If the American manufacturers ignore the requirements of the individual countries they may take it for granted that England, Germany, Italy and France will quickly recover their losses.

The automobile business formerly held by Europe is not to be despised. In 1913 Germany exported $16,920,134 worth of automobiles and $3,316,126 worth of trucks; France, $41,982,595 worth of passenger cars and $1,914,753 worth of trucks; Italy, $6,151,968 worth of passenger cars and $414,956 worth of trucks, and the United Kingdom, $11,661,935 worth of passenger cars and trucks, a total of $82,362,465, as compared with $24,275,793 worth of passenger cars and $1,737,141 worth of trucks which were exported by the United States. These huge exports were made before Europe learned the massed production that has come out of the war, and it is a certainty that unless the American manufacturer employs all his skill, not only in production but also in engineering and merchandising, he will find the export automobile business going back into old channels.

ITALIAN TRACTOR DEMAND

WASHINGTON, June 10.—Italian demand for tractors will be slight in the immediate future, according to a report by Commercial Attaché A. P. Dennis. The government purchased a heavy stock in the country during the war and there are now 6000 American tractors in Italy, while outstanding contractors with domestic concerns call for 1500 more. The sales to individual farmers are negligible. The government purchases the tractors and sends them out in squadrons of ten in charge of a non-commissioned military officer, who plows for farmers in the vicinity at so much per acre.

The plowing is quite unlike the customary American methods. The conventional plow in the plains of Lombardy is a heavy implement, ordinarily of German manufacture, with a moldboard from 18 to 21 in. deep and a superimposed jointer for the better spreading of the deep upturn of land. The combined effort of 8 to 12 oxen is required to operate this plow, and when a heavy type is used the services of two men are also required.

The weighty army tractors, which have been tried out for this service, are not adapted to the work, as two of the wheels must run either in the furrow or on the turned earth, whereas all the heavy-bearing wheels should track on the unturned soil. The reason for plowing to the depth of 20 in. is to conserve moisture.

Main building, Forest Products Laboratory, Madison, Wis.

Waterproof Plywood for Airplanes

Decision to Build DH-4 Machine in This Country Created Large Demand for Plywood—Waterproof Glue the Chief Technical Problem Involved—Strength Tests Made

WHEN plywood was recognized as a structural material for use in aircraft early in 1917, it became necessary immediately to insure its production in quantity and to improve the quality of the commercial product. Before the war plywood was made up with vegetable or cheap animal glues, neither of which was water resistant. Attempts had been made in a small way both in this country and abroad to introduce waterproof plywood made with blood albumin glue, but its use was not general and the methods of manufacture were more or less trade secrets. The first investigations of the U. S. Forest Products Laboratory at Madison, Wis., had shown that the commercial water resistant glues in this country were scarce and unsatisfactory. In fact, only four or five of those submitted by various manufacturers were even promising.

Late in 1917 the decision to build the DH-4 model in this country created a demand for large quantities of waterproof plywood, and it appeared that the supply of waterproof glue would be the controlling factor in the production of this material. Accordingly at the request of the Army and Navy Aircraft bureaus, the Forest Products Laboratory attacked the problem from the following angles:

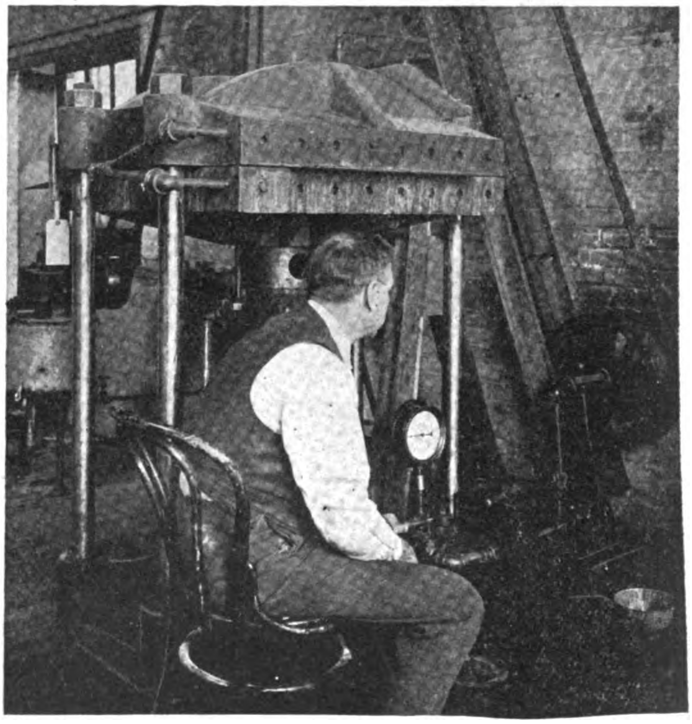
(1) Development of water resistant glues and assistance in securing their manufacture in quantity.

(2) Development of testing methods for water resistance and strength of glues and performance of routine tests on samples sent in by inspectors and manufacturers.

(3) Recommendation of glue and plywood specifications.

(4) Study of the properties of plywood as a material.

Investigation of the quantity production possibilities of water resistant glue made it very soon apparent that the supply of blood albumin would be inadequate and that if blood albumin glue only were used, the cost of the plywood would be extremely high. Meanwhile, having found



Gluing an experimental plywood panel with blood albumin glue. The press is steam heated and hydraulically operated

one company which was producing water resistant plywood with casein glue, the laboratory began work and soon demonstrated that a satisfactory plywood could be produced with this type of glue. About this time a census of the veneer and plywood industry was completed by the laboratory and it was found that if both blood albumin and casein glues were used, almost unlimited quantities of plywood could be made. The general situation was therefore relieved and the price of plywood steadily reduced.

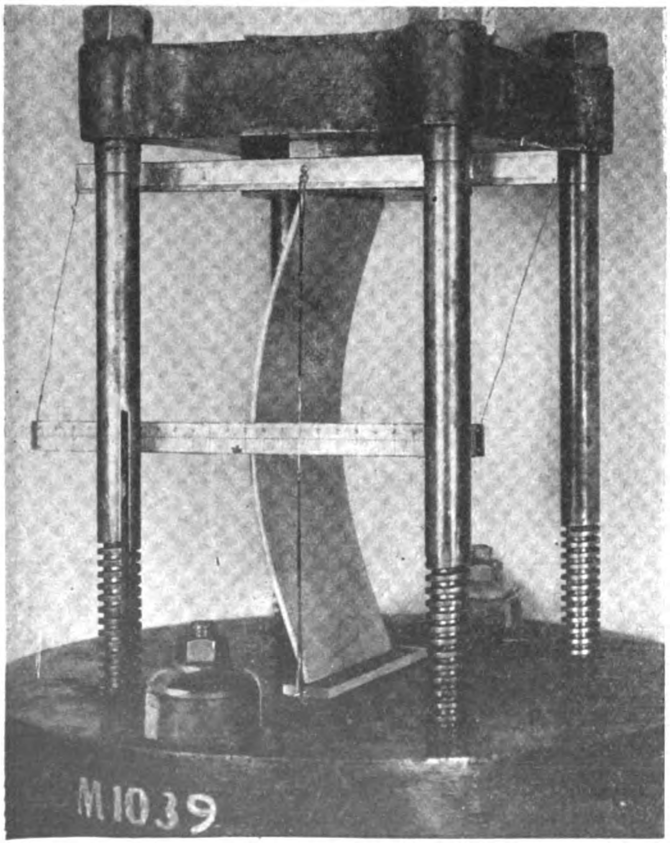
Aircraft manufacturers at this time showed a decided preference for non-waterproof plywood and it was only because the Forest Products Laboratory could supply information on the possible production of the waterproof product, together with data upon its advantages here and abroad, that waterproof specifications were adopted. It appears probable that the adoption of the non-waterproof specifications would have resulted in very few of the machines constructed from plywood reaching Europe intact.

By this time the Signal Corps had completed the organization of a plywood inspection section, and the laboratory was receiving samples of plywood almost daily from new manufacturers who desired their product tested.

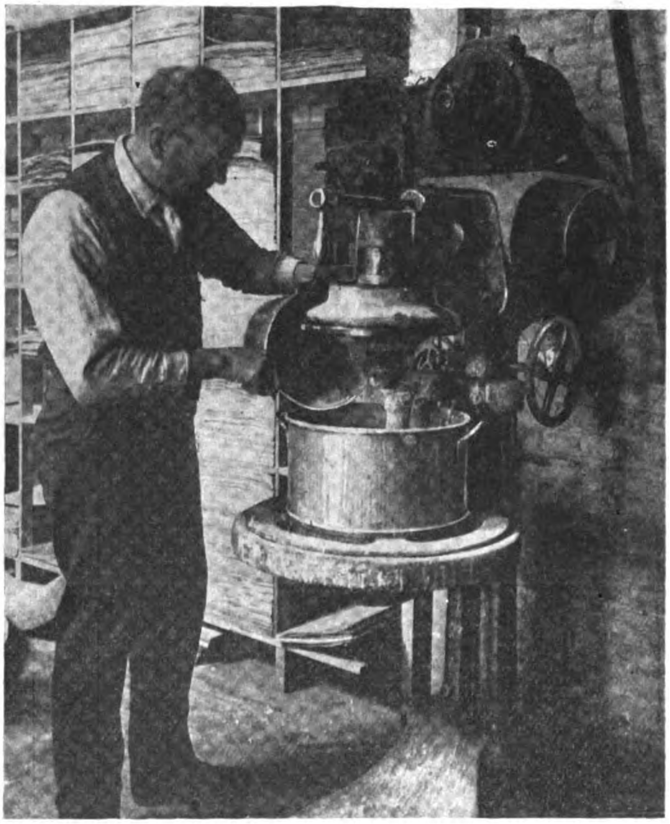
A glue inspection organization had also been started and headquarters established at the Forest Products Laboratory with a senior inspector from the Signal Corps in charge. The glue inspection force worked in close cooperation with the laboratory in the matter of glue specifications and procedure for inspection and certification of aircraft glues.

Work was under way on the development of casein glues and contact with casein producing companies and glue manufacturing companies had become well established.

During April, 1918, two commercial water-resistant casein glues were tested for shear strength in joint work



Strength test of veneer panels



Mixing a full-sized batch of casein waterproof glue

and they both developed strength equivalent to that of high grade non-waterproof hide glue. Two water-resistant glue formulas developed by the laboratory had also been supplied to certain manufacturers of glue and plywood and numerous companies were becoming interested in waterproof plywood manufacture.

During the summer of 1918 a method of gluing very thin plywood was developed and demonstrated on a commercial scale at two plants by representatives of the laboratory. The process involved the coating of tissue paper with blood glue, drying this sheet and using it with the veneer instead of a wet glue. This material was not found as suitable a substitute for linen as it first gave promise of being and but little of it was manufactured. A similar process was developed for gluing the linen fabric on propellers and satisfactory blood albumin tapes were also developed for use in taping plywood.

While the work which has been described was under way at the laboratory, additional activities of a less spectacular nature were also having their effect upon the improvement of quality and increase in production of water resistant plywood. Methods of manufacturing casein and blood albumin were investigated and specifications prepared for these and other glue constituents. Improvements were also suggested for glue manufacture and use, especially along the lines of mixing and applying glues, testing samples of plywood for strength and water resistance when sent in by manufacturers and Bureau of Aircraft inspectors, training of these inspectors in glue and plywood manufacture and solving specific problems submitted by various departments of the army and navy aircraft bureaus.

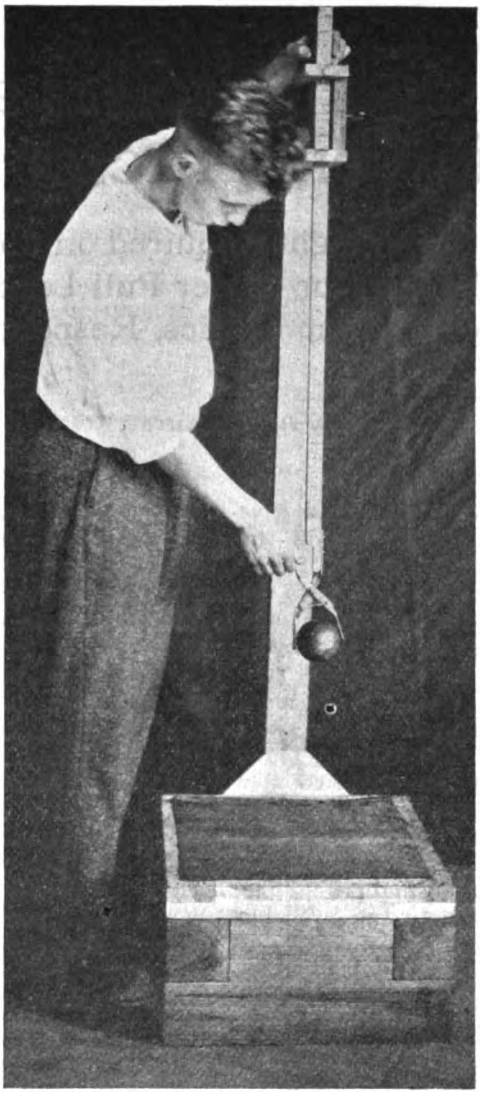
The wide distribution of the results of this work was especially helpful to manufacturers. Experts from the laboratory also made trips into the field and on numerous occasions "trouble men" were sent out to panel factories for periods ranging from a few days to one month. Their work ranged from correcting the practice of mix-

ing a glue or adjusting a press to a complete analysis of all factors of production to locate some small but important trouble.

The total result of the work of the laboratory on water-resistant glues and plywood may be summarized by saying that it practically meant the developing of a new industry, the improvement of its product to the essential degree and the saving of more than $6,000,000 to the Government by removing scarcity of plywood as a controlling factor in aircraft production.

Plans for an extensive series of tests to determine the physical and mechanical properties of plywood were drawn up in September, 1917, and the testing was begun early in October of the same year.

In outlining a series of tests for plywood, the attempt was made to test for those properties of plywood that make it a unique material of construction for airplanes. Inasmuch as the strength of plywood depends upon the direction in which the forces act, tests were made to determine the bending and tensile strength, parallel and perpendicular to the face of the panel. A piece of apparatus was devised for determining the relative resistances to splitting of plywood made of various combinations of veneer. Tests were also made to determine the relative resistances of various plywoods with conditions that tend to warp the plywood, as, for example, wetting on one face. In a series of tests to determine the physical and mechanical properties of plywood made of various species of veneer panels of eight thicknesses were tested, ranging in thickness from 3/30 of an inch to 3/6 of an inch. Moisture and density determinations were made on all test specimens. One series consisted of about fifty (50) tests and to date more than one hundred (100) series of tests have been made, which covered about thirty (30) species.



Toughness test on thin plywood

In addition to the extensive series of tests on various species of plywood, tests were also made on plywood consisting of combinations of several species of veneer; also on plywood consisting of five, seven and nine plies. Reports were issued from time to time embodying the results of the strength tests. On the basis of the tests made a specification for plywood was drawn up and submitted to the Specification Section of the Bureau of Aircraft Production. The list of species recommended included several species that had not previously been used and that the tests showed to be satisfactory, and omitted other species that were not as satisfactory.

A classification of species into four (4) groups was also drawn up. This classification gives a brief description of the mechanical properties of the species grouped and points out specific uses for airplane parts for which particular species would be satisfactory.

Detailed recommendations were made from time to time governing the species to use for particular airplane parts made of plywood. A plywood table was drawn up, giving the species, thicknesses, position of plies and number of plies to use for each plywood panel in the USD-9 airplane. Similar tables were prepared for the DeHaviland-4 and the Lepere planes.

The tests initially made to determine the relative resistances of plywood to weathering made of various species of veneer proved to be unsatisfactory, so another test was devised. In the latter test the panels were subjected to high humidities to change their moisture content and subsequently they were exposed to brilliant sunshine to lower their moisture content. Warping measurements were made at various stages. These tests showed that as a rule the species of low density were inclined to warp less than the species of high density. The tests also showed that a high ratio of core to total plywood thickness is also favorable to a reduction of warping. Panels in which the center ply is of low density veneer also warp less than panels in which the center ply is of high density veneer of the same weight.

A series of tests to determine the relative strength of screw and nail fastenings of plywood was inaugurated. The tests completed to date show that screw fastenings were generally superior to nail fastenings even when the nail used is twice as long as the screw. The tests also show that the strength of fastenings increase with the density of the plywood.

A series of tests to determine the shear strength of plywood was started. Tests have been completed on plywood in which the distance between the shear forces and width of the member was varied. The shear strength of plywood parallel to the grain of face, while not very much higher than the shear strength of the wood parallel to the grain, is nevertheless superior to the latter, inasmuch as sudden failure does not occur. A lower factor of safety may consequently be used when designing plywood parts that are subject to shear. Shearing strength of plywood when the force is exerted at 45 deg. to the direction of grain of face is stronger than wood parallel to grain of face and advantage has been taken of this fact in designing plywood members. Tests are still in progress to determine the shear strength of plywood made of various species of veneer and to determine the relative shear strength of plywood made of various numbers of plies. An extensive series of tests to determine the bearing strength of plywood made of various species of veneer and various numbers of plies is now in progress.

The effect of varying the sizes of the bolt, the thickness of the plywood and the direction in which the force is applied are being investigated.

A series of tests to determine the effect of the method of cutting veneer on the strength of plywood was completed. These tests were made on five species in which veneer was cut from the same log by each of three processes. They show that in general the method of cut-

The Influence of Hitches and Drawbar Location on Tractor Design

A Method of Calculating the Weight Required on the Front Wheels to Prevent Rearing of the Tractor Under Full Load, on the Level and on Steep Grades, Respectively

By A. W. Scarratt*

SEVERAL articles have appeared in the automotive magazines in the past few months which show the importance of proper drawbar implement hitches and how to make them, but nothing has appeared, to the writer's knowledge, which explains clearly the influence of hitches and drawbar location as related to tractor design. The purpose of this article is to cover this subject, as related to the four-wheel-type of tractor or modern design, in simple language and figures.

Let us consider first the case of a tractor doing plowing on tough, level land, equipped with an engine capable of delivering 30 hp. maximum at the flywheel, and weighing, completely equipped, 4500 lb., or 150 lb. per brake horsepower.

In order to determine the required weight distribution, we must first endeavor to compute the probable maximum drawbar pull and to establish its point of application. Two factors enter here, namely, speed or rate of travel, and efficiency. Two hundred feet per minute or 2.27 miles per hour is a good lively plowing speed for heavy work, and the efficiency or drawbar power consists of what is left after we deduct the rolling resistance of the tractor, the transmission losses, and the slippage at the drive wheels.

These three items can be approximated as follows:

1. Rolling resistance about 15 per cent of engine power.
2. Transmission losses—about 12 per cent of engine power.
3. Slippage—about 8 per cent of engine power.

Slippage is one thing often lost sight of and it is easy to lose sight of 8 per cent. That is just a nominal slippage. You can hardly notice it.

Adding up these three losses, we find that 35 per cent of the engine power has disappeared and that we have 65 per cent left to work with, which if converted into drawbar pull means 3200 lb. at a speed of 200 ft. per minute. This, therefore, is a three- to four-plow tractor, depending on the ground conditions, and being of compact, enclosed, modern design it will operate with the right-hand drive wheel in the furrow.

On a tractor designed to operate as stated, the drawbar should be located at least 14 in. above the bottom of the drive wheels—for two reasons:

First, to attach to the plow at a proper height.

Second, to have a reasonable ground clearance beneath the drawbar.

We now have the information necessary to proceed with the design of the tractor, namely, the weight of the tractor, the drawbar pull, the height of the drawbar, and the speed.

*Editor's Note.—A. W. Scarratt is tractor engineer for the Minneapolis Steel & Machinery Co., and as such has given special attention to the subject of tractor hitches.

By referring to Fig. 1 we find that there are a number of forces both active and reactive to be considered, and our object is to determine the magnitude and position of these forces in order that the system will balance, for in order to obtain equilibrium the moments of the active and reactive forces must be equal.

The one active force with which we are concerned is the tangential load applied at the rim of the main drive gear which tends to raise the front end of the tractor; this is indicated by F_1. In order to overcome the opposing loads the moment of this force must be greater than the moments of the forces acting against it.

We have assumed that the transmission loss is 12 per cent., or 4 per cent for each of three gear reductions. Then the power delivered at the rim of the main gear would be 92 per cent of the engine power, or 27.6 hp. As we are considering a slippage of 8 per cent, the speed of 200 ft. per minute is only 92 per cent of the rim speed of the drive wheels, which we will assume to be of 26 in. radius. In other words, the actual rim speed is 217 ft. per minute. Since in this case the radius of the main gear is 13 in., or one-half of the wheel radius, the pitch line velocity of the gear is 108.5 ft. per minute.

Therefore the force at the pitch line of the main drive gear—

$$F_1 = \frac{\text{Hp.} \times \text{constant}}{\text{velocity}} = \frac{27.6 \times 33{,}000}{108.5} = 8400 \text{ lb.}$$

This force naturally tends to lift the front end of the tractor and is only prevented from doing so by two reactive forces, namely, the drawbar pull W_1 and the front end weight W_2.

We know the position, direction and magnitude of W_1, and we also know the position and direction of W_2. What we want to know is the required magnitude of W_2.

It will be well to notice here that these forces all center about the rear axle, that all tendency to rotate is about the rear axle, and not the point of contact between the drive wheels and the earth. Therefore all moments must be computed, using the rear axle as the fulcrum point.

Then since the active and reactive forces are equal and opposite,

$$F_1 \times 13 = (W_1 \times 12) + (W_2 \times 84)$$
$$\text{or } 8400 \times 13 = (3200 \times 12) + (W_2 \times 84)$$
$$\text{or } 109{,}200 = 38{,}400 + (W_2 \times 84)$$
$$\text{or } 70{,}800 = (W_2 \times 84)$$
$$\text{from which } W_2 = 850 \text{ approximately.}$$

That is, W_2 must be 850 lb. in order to keep the tractor from overturning on level ground. This, however, provides no necessary weight for steering the tractor, and makes no allowance for the increased weight which is necessary when operating on heavy grades.

In a three-plow tractor there should be a surplus of about 400 lb. weight at the front end to permit of proper guidance at all times and also as an extra safeguard against overturning.

It may be well to mention here the fact that when the load is picked up very suddenly by engaging the clutch too rapidly, the power transmitted momentarily is far in excess of the maximum engine power. It is equal to maximum engine power plus the power derived from the stored-up energy in the flywheel. This condition, due to careless operation, has tipped many tractors over which would be safe if properly handled. But careless operation will be encountered and tractors must be made foolproof as far as possible.

From the foregoing it will be seen that the location and intensity of the drawbar pull have a very definite influence on tractor design.

But the example just covered is not the one which governs, so let us consider the operation of the tractor on a heavy grade of say 30 per cent, as other conditions are met with here.

Now, maybe you think 30 per cent is not a heavy grade. Well, the next time you are out plowing up and down a hill that you guess is about 50 per cent, just get a long timber and a spirit level and find out what it is; chances are that it will be about 25 or 30 per cent.

To start with, the efficiency of the tractor will not be as high; that is, you will not have 65 per cent of the engine power available at the implement, for the following reasons: More power will be required to roll the tractor up hill against the force of gravity, the footing will most likely not be as good, causing increased slippage, and the heavy implement itself must be dragged up hill against the force of gravity, thereby absorbing a great portion of the power which was available at the drawbar on the level.

We assumed previously that the rolling resistance of the tractor itself would be 750 lb. on level ground. The rolling resistance on a 30 per cent grade will be just 1350 lb. more, making the total draft 2100 lb. for this 4500 lb. tractor, provided the ground surface is just as good. With an increase in wheel slippage to 12 per cent we find that the drawbar pull has dropped to 34 per cent of the engine power, or 1700 lb., the losses being as follows:

Rolling resistance	= 42 per cent
Transmission losses	= 12 per cent
Slippage	= 12 per cent
Total	66 per cent

By referring to Fig. 2 you will note that we still have force F_1 = 8400 lb., and we also have force W_1, but it is now only 1700 lb., hence we are going to need more front end weight.

We must now endeavor to determine this weight, but we shall have to first assume what we think would have been a correct front end weight in Fig. 1. Let us take this to be 1700 lb. Then the center of gravity (fore and aft) would be 32 in. ahead of the rear axle. However, when standing on a 30 per cent grade this dimension is reduced to 27.8 in.

Now we will assume that W_2 acts downward 27.8 in. ahead of the rear axle.

$$\begin{aligned} \text{Then } F_1 \times 13 &= (W_1 \times 12) + (W_2 \times 27.8) \\ \text{or } 8400 \times 13 &= (1700 \times 12) + (W_2 \times 27.8) \\ \text{or } 109{,}200 &= 20{,}400 + (W_2 \times 27.8) \\ \text{or } 88{,}800 &= (W_2 \times 27.8) \end{aligned}$$

From which W_2 = 3200 lb., or the weight required to prevent the tractor from overturning on a 30 per cent grade. Since the center of gravity is 32 in. ahead of the rear axle when the tractor is on a horizontal plane, the resulting weight at the front wheels would be 1220 lb., which leaves a balance of 480 lb. overweight for steering when we have a total of 1700 lb. at the front end.

It is, therefore, very clear that the later case governs the design, and it should also be clear that to arrive at a correct tractor design the drawbar and its location must be carefully and primarily considered.

Incidentally, this also shows clearly the marked advantage which a light-weight, powerful tractor has when operating in hilly country, as compared to the average tractor which weighs about 300 lb. per brake horsepower of the engine. If the tractor considered in this article weighed 300 lb. per brake horsepower, or 9000 lb., it could barely propel itself up the grade considered.

As plowing is the heaviest work which a tractor is called upon to perform, the drawbar location for this class of work should be most favorable. A vertical adjustment at the tractor will hardly be required, but a sideways adjustment should be provided by all means in order that the plow may be hitched to the best advantage regardless of the number of bottoms, and right here it will be well to remember that what may be a four-plow tractor in some places is a two-plow tractor in others.

For discing, harrowing and seeding it would probably be advantageous to be able to hitch at a higher level than for plowing. There are many implements of this type in use intended to be horse-drawn which could easily

Humanity Becomes Important Factor in British Labor Settlements

Review of Developments of Conferences Representative of Workers, Capital and Government in Post-War Period Indicates a Political Growth Not Yet Achieved in This Country

By Harry Tipper

THE developments in Great Britain between the signing of the armistice and the present time have emphasized the predominance of the economic problem and particularly the industrial problem in the political life of the country. They have indicated the development of additional strength in the labor power and at the same time an increasing division between the radical element in the labor organization and the more experienced conservative majority.

The most important points to be considered in connection with the development are:

1. **The demands of the manufacturer in respect of labor.**
2. **Findings of appointed commissions representing government, labor and capital.**
3. **The growth in power of the shop stewards.**
4. **The organization of the radical division of labor in favor of industrial unions instead of occupational unions.**
5. **The promotion of the Whitley plan by the Government.**
6. **The definite tendency to shorter hours.**
7. **Lack of any considerable wage reductions.**
8. **Continuance of a large proportion of unemployed.**
9. **Difficulty in industrial readjustment and the consequent partial activity in industry.**
10. **Large developments in housing**
11. **Strong definition and consolidation of labor aims.**

The labor organizations in Great Britain have been sufficiently developed industrially and were sufficiently powerful politically to necessitate the careful consideration of their position during the war in order to provide the necessary unity for industrial war activity. The occupational unions, in the most important industries, have been recognized as the necessary machinery for effective bargaining, for a great many years, and they represented a sufficient majority of the workers in many of the industrial lines, particularly in the skilled trades required for war work, so that the Government was obliged to call them in in order to secure the orderly progress and production to the point necessary for war development.

As a consequence of this, the older organizations were directly concerned in the methods and operation of labor dilution by the introduction of women employees, in the release of essential workers, in the elimination of the usual labor privileges accorded by shop practice in England, and it became necessary in the Government controlled industries to appoint committees of labor and capital to go over the war operations of these industries.

In return for this co-operation, the labor organizations demanded from the Government an agreement that all trade union privileges would be restored upon the termination of the war and that no attempt would be made to hold the workers to the concessions which had been secured from them for war necessities. In the agreements these privileges were specifically mentioned and the Government was committed to the practical enforcement of the return of these privileges at the termination of the war.

Combined Committees of Labor and Capital

In addition to these specific agreements, the Government had been obliged to develop combined committees of labor and capital in the controlled industries and had been obliged to concede additional power to the labor organizations in several ways. It had further promised, more or less vaguely, to consider the living conditions, the housing necessities and other matters in which labor organizations were interested, when the termination of the war would permit these developments. Part of the present confusion in Great Britain is due to the difficulty which the Government is having in redeeming its pledges to the labor party and the labor organizations.

In the endeavor to fulfill some of its promises and to bring about an orderly adjustment to peace conditions the Government appointed, after the armistice, the commission to investigate the coal miners' demands and the national council, as recommended in the Whitley plan, to consider the whole industrial question. These two commissions are the first examples of triangular conferences of labor, capital and Government which have had their beginning in the political demands and practical necessities of the worker, and which have recommended definite, and in some cases drastic, changes, carrying the recommendations of the commissions much further than settlement of the immediate question.

The action of the Sankey commission was the direct result of the coal strike which started in the Welsh coal field and extended to various other coal fields in Great Britain, involving nearly 140,000 miners. The strike did not involve the Scottish miners, this union standing at one side to await the result of the negotiations of the English and Welsh unions with the Government.

Coal Miners' Demands

The coal miners' strike involved more important demands than had been placed before the British public heretofore. These demands were for a 6-hour workday, nationalization of the coal mines, increase of wages, partnership of the employees in the management of the mines, and improvement of housing and living conditions.

The employing coal operators refused all these demands absolutely, stating that any increase in the cost of production would so increase the price of coal as to make it impossible for the English industry to meet foreign competition. The threat and the coal shortage resulting from the strike were of such a serious character as to bring the Premier himself back home from the Paris Peace Conference in an effort to settle the matter.

First Miners' Movement

The first movement of the miners commenced as far back as Jan. 1, when the Miners' Federation of Great Britain adopted their new program, which included demands for a state grant equal to full trade union wages to be paid unemployed miners until work was found for them; the administration of mining conditions by joint district committees of mine owners and workers, and also for the 6-hour day and the nationalization of the mines. On Jan. 7 the Miners' Federation demanded a 30 per cent advance in wages. As there are a million men employed in the coal mines, the acceptance of these demands would have meant an increase of wages amounting to $1,000,000 per day.

On Feb. 13 the Government submitted to the miners its plan for settlement of the strike, formulated by the Premier. This offer included a shilling per day wage advance and a proposal that all the questions should be submitted to a general conference in which the employees should have equal representation with the employers.

The miners absolutely refused this Government offer, but, despite their refusal, the Prime Minister went ahead with his plan and a commission was appointed to make a full inquiry into conditions in the coal industry. Both the investigations of this commission and the strike continued until March 17, when the miners agreed to withhold their strike for a short period, pending a preliminary report of the commission. This preliminary report, when returned, practically conceded all the miners' demands.

The recommendations of the report were agreed to by the Government, and although the investigations of the commission still continue, the entire trend of the investigation is favorable to the miners and it is practically settled that the following conditions will be put in force:

1. **A 7-hour work day (with a 6-hour day after July, 1921).**
2. **Two shillings per day wage increase.**
3. **Voice of the employees in the direction of the mines.**
4. **Either nationalization of the coal mines or unification of same under some joint control of private ownership.**

While the testimony of the employing coal operators and of many manufacturers before the commission was to the effect that, conceding that the miners' demands would so increase the cost of coal as to offer a serious handicap to British industry, particularly in competition with America, nevertheless the condition of the miners was so bad that on humanitarian grounds alone their demands should be in the main conceded.

While, in a way, the result is a victory for labor, yet it is more than that a victory for humanitarian progress and an acknowledgment as to the right of the worker to a higher standard of living. The great coal mine strike was not the result of any new conditions or evidence of any new phase of social unrest. The condition of the coal miners has long been a subject of public sympathy in Great Britain and public opinion had much to do with the final granting of the miners' demand.

One outcome of the investigation was to show that the profits of the mine owners ran from 1 to 2 shillings per ton prior to the war and as high as 4 and 5 shillings during the war.

The action of the Government in relation to the coal strike was based upon three reports submitted by the Coal Industry Commission. One of these, made by the more radical members, recommended allowing of the full claims of the miners. Another of the interim reports dwelt more on the actual statistics of coal mining operations, and the third interim report, called the Sankey report, offered a definite recommendation which the government finally decided to adopt. This report states that the increased wages proposed will mean the distribution of an additional sum of $150,000,000 per annum in wages among the colliery workers.

The interesting part of this report and its adoption by the Government lies in the fact that the commission included eminent men of various shades of opinion, with representatives of the miners and the manufacturers and also public men of a legal and general training. The report is generally referred to as the Sankey report because of the fact that Judge Sankey was the chairman of the commission. The condemnation of the present conditions of the workers in the coal mines is very definite and inclusive in this report.

The Whitley Plan

The national council, which was authorized by the Government to consider the whole question of industrial development, labor conditions and the things which should be done to produce industrial peace, was called in connection with the Government's promotion of the Whitley plan. The Whitley plan has been mentioned a number of times in this country and the general purpose of the plan and its acceptance indicate the recognition by government and by general public opinion in Great Britain of the necessity for equal representation of the workers in control and management of industry, in so far as that control and management concerns matters directly relating to the workers.

This recognition of rights is acknowledged in the acceptance of the Government of the so-called Whitley scheme. The adoption of this plan is the direct result of the unusual conditions existing during the war which compelled the government to require full co-operation between employers and employees, with state authorities, in the control and conduct of industry to permit the securing of the greatest possible plant efficiency and the largest possible production of materials.

National Council of 400 Recommended

The recommendations of the Whitley report submitted to the Government during the war as a plan for future labor policy were put into partial effect, or at least the first step taken, in March of this year, when a National Conference was held, being, in fact, a joint committee meeting of employees and employers similar to that recommended in the Whitley plan. At this conference it was proposed that a National Council of 400 should be formed to be composed of half capital and half labor. It is intended to use this national body as a consultative authority of the government on all industrial matters. Its members are to be elected by the trade unions and by the associations of employers. It is not clear, however, as to whether this proposed National Council is to be joined up with the Works and Districts Committees called for by the Whitley plan.

There appears to be little open opposition to the Whitley plan, as set forth in the report to the Minister of Labor, which he, representing the government, has formally announced will be put into effect. In a way, the

plan is based on participation of employees in the management of each separate industry in a manner similar to the "employees' representation plan" adopted by many industrial concerns in the United States. The plan differs essentially in providing joint district organizations and a joint national council. This plan briefly calls for the following organization:

1. **The establishment for each industry of an organized body, representative of both employers and work people, to be called the Works Committee, to consider and act upon all matters relating to local labor and industrial conditions.**
2. **The formation of District Councils representative of the trade unions and of the employers' association in each industry.**
3. **The formation of Joint Standing Industrial Councils to be equally representative of the employers and of such industries as are not already represented by trade union organizations, the purpose of this being to secure a representation for the masses of unskilled labor not included in the regular union organizations.**

It is the purpose of the plan to have the Works Committee and District Councils act upon matters of a local nature which can be decided by them, including the conditions of employment, the methods of fixing, paying and adjustment of wages, and the establishment of regular methods of negotiations for differences arising between employers and work people and means for preventing unemployment.

It is intended that the National Council should only take up matters of general or national importance, such as legislation, state control, etc.

The difficulty of succeeding with a general employer-employee co-operative plan with the unskilled workers, not included in the regularly organized trade unions, is fully recognized by labor leaders and industrial economists and the subject is quite fully covered in a recent "second" report of the Committee on Industrial Relations of Great Britain which originally outlined the so-called Whitley plan.

Report Does Not Favor Compulsory Arbitration

This committee recommends that the existing Trade Boards Act, enacted because of the needs of the war, shall be continued. The original purpose of this act was to provide means for establishing a minimum standard of wages, but in addition to such purpose, it is now proposed to use this medium for the organization of "Industrial Councils" for unorganized industries.

It is noteworthy that this second report of the Industrial Relations Committee does not favor compulsory arbitration, stating that both employers and employees are opposed and that imposition of forced arbitration would lead to further unrest. Neither does this committee favor compulsory methods to prevent strikes, pending negotiations.

In promoting the Whitley scheme, the government does not intend to abandon for the present the other existing government agencies provided for industrial reconstruction and for promoting better industrial relations. One idea is to link up the National Industrial Council, to be organized under the Whitley plan, with the work of the present Trade Boards and other joint representative industrial organizations organized during the war. The government is also maintaining trade union advisory committees at the headquarters of the government departments, as well as local labor advisory committees in various localities.

It is noteworthy that the Department of Labor continues to use its Trade Board organization for the adjustment of conditions relating to the employment of unskilled labor not organized by any of the established unions. Only as recently as February, the government took action regarding wages in the trades devoted to the manufacture of garments, knitted articles, embroidery and various needle trades, which have no representative unions.

While the Whitley plan was worked out by a committee representative of both employer and employee interests, and while there is no open opposition to the plan expressed by the union workers, yet there has been some evidence of suspicion on the part of union labor interests against the idea of works committees. Doubtless this position is based on ideas which prevailed to some extent in the United States, that by the building up of works committee or employees' representatives, to deal with the employers in conference, the result will be to weaken the strength and importance of the local trade unions.

"Triple Alliance" Stands Aloof

Although the National Industrial Conference continues to function and at its meetings subjects of the greatest importance to labor are considered, even such questions as giving to workers a direct share in the control of industry, yet it is notable that the "Triple Alliance," the most powerful of all trade union combinations, stands aloof from this government effort to solve the industrial problem by co-operation and conferences. No delegates or representatives of this union organization officially took part in the proceedings of the recent National Industrial Conference.

Leaders of this union organization do not admit that they are opposed to the National Conference or the Whitley plan or that they will refuse to enter into them, excusing themselves on the ground that other important affairs have prevented them from participating. It is not certain that this large trade union element will eventually co-operate in the National Conference or the Whitley plan. The Whitley plan is supported strongly by the National Labor Party leaders and is part of the policy of the present government administration headed by Lloyd George.

Great Britain's Relation to Labor

The important position which the government of Great Britain holds in relation to all labor and industrial questions is shown by the history of recent events. The great coal strike would have resulted in serious disaster to British industry if Premier Lloyd George had failed to secure a compromise agreement.

The government is working hand in hand with the organized trade unions, and that it recognizes the trade union power fully is evidenced by the refusal of the government to intervene in any way in the recent strikes on the Clyde and elsewhere, basing its opposition on the wishes of the trade union executives. In the case of Glasgow, although the Lord Provost asked for intervention by the government, the administration officials refused, stating that such action would undermine the authority of the national trade union representatives.

Although the Whitley plan of the government is not yet fully in operation it has been applied in several of the separate industries, notably in the manufacture of pottery, rubber and watches. These have a full system of shop committees, district councils and national councils organized and operating.

These developments indicate the extent to which the labor situation in Great Britain has become a political matter and the extent to which the labor organizations can enforce the political consideration of their demands. They illustrate the extent to which the Government has recognized the necessity for change in the general organization of industry in order to preserve harmony and to insure a reasonable, peaceful development.

It is not possible, as yet, to determine the ultimate success of the Whitley plan, or the other methods of governmental consideration of the labor situation, because labor opinion itself is divided as to the improvements to be secured and the methods to be adopted in securing those improvements. Probably 65 per cent or 70 per cent of the workers would be very glad to return to pre-war conditions if pre-war prices could be returned.

Leaders Recognize Value of Slow Development

The older and more experienced leaders in the labor ranks see the necessity for slow and careful methods of development, and even the aims of the labor political party itself, as shown by their reconstruction platform and the statements of the party leaders, specifically indicate that there is no expectation of accomplishing these things in any short time; and that the main object before the party is to see that each development builds toward the final platform which they propose to support. The great danger in the situation arises from the division of opinion within the ranks of the labor organizations as such, both as to the aims which can be immediately fought for and the methods which can be used in endeavoring to secure them.

The growth of the shop steward system in Great Britain has had a very distinct tendency to remove the power from the leaders of the national unions, or at least to take away a sufficient amount of that power to make it difficult for such leaders to control the whole body of workers under any agreement. This is evidenced by the history of the strikes which occurred between the signing of the armistice and the present time.

Strikes Reaction from Wartime Production

Unquestionably, a number of these strikes were made possible because of the general reaction from the war production necessities, the restrictions imposed during the war, and the strain which the country suffered for several years during that period. These strikes were called for demands which varied considerably. They were sufficiently widespread to indicate a spirit of general unrest, but more particularly they were based upon the local demands of the workers in some part of the country led by the District Allied Trades Council, which is the shop stewards body. They were frequently called in direct opposition to the national organization, of which the strikers were members and conducted without the approval of such organization.

In a number of cases the union leaders made common cause with the Government, and it is interesting to note that the strength of the labor organizations, in their power over their own ranks, was still sufficient to enable the employers to refuse any dealings with their own employees except through the recognized union leaders. The shipbuilding strikes, which were particularly bad in Belfast, where they developed almost along the lines of a completely socialistic government, were broken because of the division in the labor ranks and the regular union organizations were greatly strengthened by the defeat of this movement.

The great strike of the Triple Alliance, which is a co-operative organization of the three great industrial unions, railway workers, miners, and the transport workers, was one of the most difficult to settle, and it is not certain even now that this matter has been sufficiently settled to eliminate the possibility of further strikes in the near future.

Strikes have crept into the cotton district in Lancaster, in the engineering and shipbuilding trades, in the electrical trades, all of which strikes finally collapsed without any material change in the situation except agreement to reduce the hours to 47. Almost all the strikes were unofficial strikes. They were conducted by the local shop stewards, and were not recognized by the older leaders. Their breaking down is evidence that the radical element, which favors the direct action through the shop-steward system, is not yet sufficiently strong to endanger the recognized union organizations, although the number of men who became involved in the strikes indicates that there is a very large movement among the labor bodies to demand clearer and more direct action in connection with their local disputes than is provided through the regular organization.

This is partly due, of course, to the reaction from the war and partly due to the growth of radical opinion in the ranks of labor, which threatens to disrupt the labor organizations themselves.

Industrial Unions

A feature of this radical development, which has grown out of the formation of the shop-steward movement within the Allied Districts Trades Council, has been the movement in favor of industrial unions instead of occupational unions which form the machinery of the recognized labor organizations. This development arises more out of the political labor party and its growth than it does out of the actual union organization; but the ability of the Allied District Trades Council to enforce its demands, where the old craft unions have been unable to enforce them, has developed a strong opinion in the labor ranks in some cities in favor of industrial unions all through.

This has attracted to its side a number of social reformers and a considerable body of opinion which lies outside the labor ranks, but which is affiliated with the labor party as a political organization. So far, the tendency toward industrial unionism is not of importance in Great Britain, and it is not likely to become so if the tendency of the present developments continues. It is probable that further economic troubles of a more or less serious character will occur in Great Britain, due to the conflict between the industrial unionism as represented by the shop-steward system and the craft unionism as represented by the older organizations, and that the radical element will find sufficient following to induce them to make excessive demands and attempt to enforce these.

There is no indication, however, that these movements will assume sufficient importance to materially affect the developments which are taking place or to interfere with the orderly progress which is being made in the settlement of these important questions.

In all the actions which have occurred in meeting the strikes in Great Britain since the armistice, in all discussions of the labor questions in the triangular conference between government, capital and labor, there has been a distinct and definite tendency toward shorter hours and work. In connection with this matter, of course, it must be remembered that in Great Britain the hours of work have been longer in the past than those usually obtaining in this country, and the historical background suggests an importance in connection with this demand which it does not possess in the United States.

The 48-hour week is practically admitted in all types of industry to-day in Great Britain. In the case of the shipbuilding trades strikes, engineering trades strikes in Belfast, Glasgow, and other points in the British Isles, the demands for working hours range all the way from a 47-hour week to a 30-hour week. The decisions were made upon a 47-hour week in London. While the same organization in Belfast was demanding 44 hours there was a strike in Glasgow for a 40-hour week. Most of these strikes were unofficial, and the engineers' and shipbuilders' strikes were first broken by the decision of the Liverpool Federation to continue work.

The Liverpool Federation stood 10,000 in favor of 44 hours and 8000 in favor of a 40-hour week. These strikes failed, but the 47-hour week was adopted and it is probable that further development will necessitate a reconsideration of this and the elimination of three hours, making it a 44-hour week. In the report of the commission appointed to deal with the coal mining industry the recommendation, on account of the peculiar conditions in this industry, starts with a seven-hour day until July, 1921, after which time a six-hour day shall be considered.

At the last annual meeting of the Lever Bros., Ltd., of Port Sunlight, near Liverpool, the directors of this company reported that they had adopted a 36-hour week.

In practically all of the strikes there has been a tendency to reduction of hours, and the demands of the unions lie about half way between the 48-hour week and the 40-hour week. In some few cases local organizations have demanded smaller working days than that, but there is a very large opinion, as indicated by the votes and the actions of the different unions in the trades, for a week ranging between 40 and 47, with a majority of the workers in favor of a 44-hour week.

If the votes and strikes of the scheduled trades involved indicate anything in respect of the future probability, they suggest a very definite, powerful demand in the organized unions of Great Britain for a shortening of the traditional hours of labor and it does not look as though the present 48-hour week would last very long without further attempts to reduce it.

Up to the present there has not been any great tendency toward wage reduction in any of the large industries, although in some of the smaller branches of trades there have been reductions. In fact, in some of the large industries, particularly in the railroads, which are under government control, and the cotton and engineering trades, there were demands for increased pay. In the settlement of the railroad strike there was a considerable increase allowed the workers. In the settlement of the cotton strike, which occurred just after the armistice, because the cotton mill owners repudiated their promise for increase made during the war, a 50 per cent increase was decided upon with an arbitration settlement to finally determine the matter. The coal miners were allowed a 30 per cent increase.

These advances are evidence that there is no tendency for wages to come down, although the unemployment continues at a very high rate.

Reports from Great Britain show unemployment in the United Kingdom on April 14 of a total of 246 unemployed per 10.000, and about one million pounds per week was being paid out as unemployment wage. The unemployment as reported at the beginning of May was slightly less and the last reports indicate a very slight decrease. It is evident from the conditions in the very important industries in Great Britain that the question of readjustment is a very difficult one and that it will be some time before the unemployment rate decreases to a reasonable percentage.

Unemployment Insurance

The obligations of the government for unemployment insurance must continue to be high for a considerable time and will probably amount to about two hundred million dollars this year. The extent to which factories were increased in Great Britain for war purposes has not been understood in this country, and it can hardly be measured without a knowledge of the preceding circumstances. The conversion of Gretna Green, which before the war was a village of one street and probably 30 or 40 houses, into a city with ammunition plants aggregating approximately 9 miles long by 3 miles wide, with the necessary housing and other accompaniments, is a little indication of the way in which manufacturing facilities grew during the war. The difficulties entailed in turning these facilities over to peaceful occupations so as to maintain the employment which was built up during that period.

The demobilization of the soldiers has not occurred in Great Britain at the rate at which it is proceeding in this country, and this has kept down the unemployment to some extent; but it is to be expected that there will be a great deal of unemployment in Great Britain for some time to come on account of the enormous difficulties in the way of adjusting all manufacturing facilities to the necessities of peaceful work and reviving the trade which was lost in the concentration upon the war requirements.

One of the demands made by the labor party in connection with its reconstruction platform was the demand for better housing. This has been a subject of political controversy for many years in Great Britain and there is no question but what the housing conditions in many parts of the country were poor before the war and these housing conditions were not improved with the consolidation of manufacturing demanded by the war necessities.

Millions to Be Expended for Homes

In the United States we have some housing problems, but we have no such problems as those confronting the people in Great Britain, where their population has been shifted to a very much greater degree and where the percentage of men going into service was so much higher a proportion of the population. The development in building is going ahead in a good many districts at the present time, and it is expected that millions of pounds will be expended by the government and the local government bodies for the erection of workingmen's houses throughout England, Scotland and Wales.

It is not expected by any of the parties, or by any section of public opinion, that the housing problem can be settled through private means, and it is probable that the government will be obliged to assist in this program for a number of years in order to introduce the conditions which should prevail. It is not only that the number of houses required are not available, but the character of the houses for workers in Great Britain is inferior to those in the United States, and the facilities for sanitation, etc., are not nearly so complete. Bills have been introduced in the House of Parliament offering various solutions. The programs are not finally settled, but it is probable that the government will aid in the financing of local housing operations.

At present the government is financially helping the public utilities associations for the building of houses, and some of the local trade union organizations are contemplating qualifying themselves, legally, to act as building associations to enable them to secure this government financial aid. Our reports on the resumption of building activities in Great Britain indicate that in several of the districts this resumption shows an increase of 300 per cent or 400 per cent in the last two months.

War Has Helped Define Aims of Labor Party

The general situation in Great Britain shows that the war has developed a definition of the aims of the labor party as a political party and the labor organization as a craft union which consolidates the demands of labor to a much greater degree than was visible before the war. The aims of the labor party are summed up effectively in the platform for reconstruction which has been closely adhered to in the later speeches of the labor party leaders. This platform is very radical in many of its ideas and would be called a socialistic platform in many respects.

It should be noted, however, that the labor party in speaking of workers includes all workers, brain and hand workers, in the term workers, and in this respect its definition is entirely different from those of the craft unions. The definition it makes between labor and capital is the definition of those whose toil enriches the community and those who make no production effort.

The consolidation of these demands in the political aspect of the labor question, as well as the definition of the demands of the draft unions, has resulted in the general admission of some points which are still in controversy in many other countries.

Public opinion in Great Britain, including the opinion of employers, acknowledges the right of the worker to representation in the management, at least in respect of the things which concern his working surroundings and employment. The general statements by important manufacturers, by prominent public men of all types and by those whose words would count in Great Britain, indicate that the employers themselves and the general public recognize the obligation of industry and society to provide the worker with certain stable conditions of living and with certain opportunities for development, as well as a measure of partnership in the decision of the governing principles under which matters shall be arranged.

During the past six months a group of employers representing the principal plants in one of the most important British industries met in London and prepared a set of guiding principles relating to the management of their business, which outlined their duties as regards wages, the place of the worker in the management, security of employment, disposition of the profits and other subjects.

In the matter of wages, their conclusion was:

"These should always be sufficient to enable a man to marry, live in a decent house, provide means for the upkeep of the physical efficiency of the family with a margin for contingencies and recreation."

This declaration was in effect in favor of the naming of a minimum wage based on a cost of living. Continuing, the declaration of principles says:

"The worker asks to-day for more than an improvement in his economic conditions. We admit the justice of this claim and we must co-operate with him and treat him as we should wish to be treated ourselves. We propose to create suitable machinery for this purpose but believe that the more essential thing is the living desire to give full expression in a belief in right relations. Experience on shop or works committees trains the members in participation. We shall promote the formation of such committees."

It is this admission of the points of agreement between the public, capital and labor which gives rise to the hope that the adjustment of the situation in Great Britain will be made with orderly development, although it cannot be made without some economic disturbances. Unless the radical element in the older organizations becomes much stronger than it is, the control of the situation by the craft unions and the statement of the leaders of the older organizations "that progress must be made a little at a time" indicate the general feeling that there is sufficient groundwork of common opinion upon the necessary developments to provide progress which will be satisfactory.

Peace Will Offset Radical Demands

The conclusion of peace and the concentration of governmental activities upon domestic political issues will hasten the orderly development and offset the radical demands that have a tendency to accumulate during times of unemployment and industrial depression.

It is clear, however, that in Great Britain the position of capital, worker and government will be determined from a viewpoint which we would consider more radical than anything at present on the horizon in this country and the conclusions arrived at will tend to admittance of principles which we are not prepared to admit as axiomatic in the United States.

There is no doubt that Great Britain of pre-war days as a political government, has gone and that the labor party power will be felt in all the political developments of the next few years. The radical opinion may force political consideration of matters which should not be considered from that standpoint, and for a time labor power, forced by the radical demand in its own ranks, may go beyond wise development.

There is some tendency of this kind to be observed, but it is admitted that the position of the worker, politically and industrially, has been entirely changed and that it is necessary that recognition be given to him in a different way, so far as Great Britain is concerned.

NEXT WEEK Mr. Tipper will discuss the developments in labor conditions in the United States since the signing of the armistice. This will be a comprehensive study of the situation, especially applicable to the automotive field and will be a document of great importance to every employer of labor. The development of the labor organization situation and the attitude of employers are traced through this period of surprises.

The Experimental Car

An Outline of the Methods Used in Developing New Models for Quantity Production—Experimental Department Organization and Routine

By C. Roy Watson

TO make automobiles that sell like hot cakes on their inherent merits is no chance nor haphazard business. Every firm desires to have its product held in high esteem by the buying public and to enjoy the privilege of selling cars when the mediocre firms are feeling slow times.

Granted a good manufacturing organization, all that remains to make a success is a well developed car, and that means good engineering, checked by able experimental testing. The writer's purpose in this paper is to give the methods of experimental car testing developed in several years of his experience with a leading manufacturer. Like most things in these days of highly detailed design and efficiency, a great deal of method or system has to be used in the experimental work to get good results. I am not going into the planning nor designing phases of engineering work, except as it borders on the experimental.

How Not to Do It

Many automobile makers to-day do not fully realize the importance of thoroughness and high standards in the experimental work. The usual procedure when a new model is brought out is to build a single experimental car composed of the first guesses of the engineers. The motor is perhaps given some kind of a block test and the car goes to the road where it is driven irregularly by an ordinary tester, and on week ends by more or less biased and theoretical engineers. Replacements and new devices are put on from time to time and the developments disturbed by tightening ups and "babying." Time on the road is wasted in making advance demonstrations to dealers and trifling in general. The result is that little progress is actually made in developing the model, and that when the cars go into production a ferocious scramble ensues to patch last hour discoveries, loose odds and ends and unforeseen manufacturing difficulties. This means expensive delay in production, an increased scrap pile, profit killing replacements and negative advertising by consumers.

Method or System

The time necessary to develop a new model to the point of production varies according to the amount of newly designed detail. An old model that has successfully stood the acid test in the public's hands, on which there have been made a few minor detail refinements, requires little time, although a standard of, say, 30,000 miles of methodical road testing is always a good precaution. Such a test represents an average of five years' use in the average owner's hands. Naturally, hot and cold weather, wet and dusty roads, etc., should be covered by the test in order that it may be thorough.

In the case of an entirely new design the drawings must have been completed and the commercial arrangements for stock assured. The experimental car parts must then be built and prepared and the component units pass through the laboratory tests, leaving a period of from four to six months' time for tests of the complete car on the road. If extremely radical designs are to be incorporated in the model, much more time has to be given to the doubtful features, as many an engineering organization has had to make a right-about face with some features that could not be made practical in time.

After the experimental cars have developed all the bugs and the machine is a success, the manufacture of parts for the new model should be sandwiched between the production of the current model, and the development of tools, material specifications and the shop organization of means and method be completed. In this way the new product can be smoothly dove-tailed into the end of the old season's product and the common losses and delays in starting the new season avoided.

In order to run the whole gamut of service that the motor public will expect the car to stand up to creditably, and to systematically handle the complex details of development, three experimental cars had best be built. With one car alone all the eggs would be in one basket, and in case of a road or shop accident all the work done might be lost. In the section on the system of testing out it will be seen why the third car is advisable.

Outline of the Work

The experimental staff should be a highly trained and talented force, with such equipment as is necessary to do the work efficiently. They should work in an atmosphere favorable to keen observation and originality. With a live firm it seems that there is ten times as much work to do as the Experimental Department can handle. In the automobile business resting on the oars is permissible only to the few firms who are greatly in the lead. Some have taken a hard back slide due to relaxing the aggressive policy. A leader must work hard to retain his position. I will outline the experimental work advisable to all firms in a season's program:

A—Developing the new model.
- 1—Building the experimental car and parts.
- 2—Laboratory tests and developments.
- 3—Road tests and developments.
- 4—Acceptance and commercial co-operation.

B—Super-testing the factory product.
- 1—Acting upon agents' complaints and suggestions.
- 2—Experiments on employees' cars.
- 3—Replacements under commercial exigencies.

C—Research.
- 1—New designs and accessories submitted.
- 2—Commercial material substitution.
- 3—Competitors' car study.

Super-Testing the Factory Product

From the outline it would seem that there is a good deal to do after the car is put into production. When the factory starts to build the car a certain amount of co-

operation is needed from the experimental force to straighten out difficulties in manufacturing and to closely inspect the new production to see that it is fully up to the highest standards of quality. One of the first cars of the production should be taken out by the experimental testers and driven 10,000 miles under all conditions to be sure that all is going well with the new product. The factory test is generally a short affair and only serves to show the most superficial defects. In the "super factory test" defects in workmanship, materials, heat treatments, accessories, etc., are found without waiting for the agents to get a number of cars into the public's hands and in time figure the trouble out and then give the alarm. This test always saves many times over what it costs, and should be repeated two or three times during the season. These cars, with the other experimental cars, can be taken into the shop, standardized and refinished somewhat and sold at cost to the employees, who will eagerly bid for them. In selling such cars a resale limit can be imposed reasonably and perhaps some minor experimenting carried on, on condition that the owner supplies the experimental department with his views and findings. There is nothing like getting an expert to personally get the tools in his hands and minister to perhaps some of his own deficient contributions in the model. He soon sees the point or helps chafe the guilty parties.

Refinement and Substitution

During the season the agents and others make criticisms or suggestions for minor refinements. With judgment, these minor changes can be thrashed out on any car under test, where they will not interfere with more essential things. In the case of the failure of supply during the season, of any material or part, due to some commercial reason, experiments can likewise be made for substitution.

Research

Innovations come along from time to time for study and development. These are the things that add selling attractiveness to the product or cut manufacturing cost. They have to be sandwiched into the current experimental work, or, if important enough, a car may be provided specially for them. As a rule, an intricate device should be installed by the parties submitting the same, and with prudence a certain amount of collaboration can sometimes be permitted. Often only the germ of an idea is brought in and nine-tenths of the adaptation and development has to be done by the car maker to get the device into practical form.

Study of Competitors' Cars

Some makers study competitors' cars and get many ideas, both of operation and construction. Like the foregoing work, this is best done by the trained talent and the comment of various experts of various viewpoints. The engineers should first look the car over in turn and drive it on week ends and evenings, then have a clever tester measure the performance in every way, run up the mileage for developments, disassemble for inspection and then have an expert draw up an analytical comparison to facilitate the study.

Equipment

A set of rooms, or, better, an efficiently arranged building, should be provided exclusively for the experimental work. A good arrangement is to have one large and one small door near together. A guard must be posted at the doors and the place not allowed to become a curiosity shop for prying individuals. People on business should be received by the guard in an ante-room which is surrounded by the necessary offices. Following in order grouped around a common stock room should be the machine shop, laboratory, and garage with large communications and doors. The shop and garage should have partitions or small rooms on the side for special work, and the laboratory should have a muffled wall testing block; a special corner can be used for dead stock. The machine shop should contain mainly tool maker's machinery, and the size should depend on the quantity of work it is expedient to do in the factory, in keeping with the required degree of secrecy. The laboratory contains motor testing equipment and apparatus of all kinds to make quantitative and chemical tests. The garage contains plenty of parking space, facilities for building, filling, cleaning and repairing cars, etc. The location of this department should be such as to be hidden from public and factory view and it should contain the usual conveniences for the men so as to keep them within their own sphere.

Personnel

The men doing experimental work must be trained experts in their specialties and not ordinary mechanics and drivers. They must be deeply experienced, practical, critical, and ingenious. Ordinary wrench slinging dubs have no place in the work except to demonstrate perhaps at a later stage how the car may be abused by careless owners and poor garage talent. The organization of the staff is as follows:

The experimental engineer in charge has a general routine supervision over the whole work, sits in the conference of engineers and must be able to keep a smooth, alert frame of mind among his assistants, some of whom might be of more vital value in the work than himself. Three foremen of the machine shop, laboratory and garage look after their respective divisions and make reports in writing and suggestions directly to the forum of engineers. Lastly, the chief experimental tester is like the home guard in a football game—the last man to stop bad design and mistakes. He must be very thorough.

All must work in a friendly, unbiased, and critical atmosphere and be encouraged to churn up data and ideas without any fear or favor. All should be assured that they are under the direct protection of the head of the company and should be cautioned to secrecy outside the department.

Constructing the Experimental Cars

It is necessary at times to get special work done in the factory on the highly specialized production machinery. In fact, it is desirable that it should be done for training as far as is consistent with workmanship, expediency and secrecy. The latter factor need not be much worried about ordinarily, at least not in the case of conventional designs and where the volume of such work obscures the identity. A general policy throughout the conduct of the work, of not allowing doubtful characters to get more of the plan than is helpful in their detail of the work, serves to keep them from getting all the links in the chain and having enough to do any harm.

In the process of making the experimental parts—and in assembling them together, expert study must be given to every detail in order that data may be secured at every stage of the work for checking developments in the tests, that they will be identical in material, heat treatment, limits, etc., to what they will be in the manufactured product, that conflicts and inaccessibilities are eliminated and that manufacturing facility is incor-

porated. Every piece should be analyzed for material, and heat treatment where important, in order to insure that everything is up to specification and that no parts materially weaker or stronger or more or less durable than the normal get in to ruin the conclusions at a later stage of the testing-out work. Likewise, the parts should be carefully checked for alignment, dimensions, finish, etc., and in some cases both extremes of the limits provided for trial in parallel tests. Axial lines, bench and description marks should be inscribed on all new and doubtful parts and assemblies, in order to later study any bending, twisting or undue wear that may occur.

The careful stamping of parts not standard should be looked to, and anything needing special identification should be stamped where the mark is most visible at all times. Parts with rough and indefinite limits should be carefully measured, and data kept in a tabulated diagram. Likewise, diagrams of dimensions should be kept of all parts that wear. A ten thousandth part of an inch in such data is a good limit of measurement. There is nothing more exasperating than to get a break, bend, twist, reduction or wear effect and not have reliable data to go back to in drawing a conclusion. Workmanship in experimental work is a bugbear, and too much cannot be said on the subject. Neglect in this matter wastes time and money.

The valuable detail judgment and co-operation of manufacturing specialists will add value to the work, provided it is diligently collected and tactfully handled. Remember these things mean savings in money, and the car is composed of almost millions of little details. This is a little sermon on the way.

A skeleton chassis, such as some firms employ in testing out, is only a small part of the car. It is a waste of time to stop here. The scientist's assertion that every atom in the universe has a relation to and an effect on every other atom applies especially strongly here. All the superimposed and attached parts and the equipment have their mutual fits, their co-operative functions, their clearance relations, their stiffening and weakening influences, their weight effects and must be in position when making the test. The complete car should go to the road fully equipped with no ifs or ands.

The body, top, curtains, shields, fenders, control mechanism, piping, wiring, etc., are portions generally designed by different hands, and the complex locations in different planes make many things a matter of individual fitting and adaptation, and templates must be made and allowances fixed early. Often very embarrassing and ridiculous conflicts are found in the finishing up stage where the work is improvidently conducted. The sooner such defects are found and eliminated the better, as elaborate body and sheet metal dies and forging tools take long periods to alter.

Laboratory Tests

Many of the parts, accessories and sub-assemblies need laboratory testing before going together. This is a very important work, and volumes can be written on the equipment and procedure necessary to do this basic work thoroughly. Things are in general more accessible in the laboratory than on the car.

The complete car on the road should be regarded as the final elimination test or the last checking out of things overlooked and unforeseen. Every defect found is something of a debit mark on the thoroughness of all concerned in preparing the experimental car. The more closely the laboratory can calculate and judge to road performance the more effectively their work will be done.

The standards of efficiency in laboratory work are rising fast. Things are more accessible for fine detail study in the laboratory than in the car. With the tendency toward light weight construction, cleverly arranged physical tests eliminate the clumsy method of risking the tester's life in the road test. Material and heat treatment inspections are conducted here. The motor is tested here for internal friction, power, flexibility, lubrication, balance, cooling, ignition and carburetion and its shortcomings are eliminated. The clutch and transmission are tested for inertia effects, holding, slipping, shifting, lubrication, etc. The rear axle and universal joints are tested for lubrication, heating, etc. Accessories like tire pumps, horns, speedometers, fuel feeders, primers, etc., are also gone through in a suitable way. When the car is completed the spring action is studied by weighting and jacking up and down, and interferences are studied. The limitations of the bumpers and rebound straps are noted and the arcs of axle movement all compared to the angles and sliding of universal joints, brake rods, torque bars, etc. Many incalculable and unforeseen details operating through several planes like control rods, under pans, and accessory connections, etc., must be corrected here. Weighting of the parts and sub-assemblies should be done also for comparison and future reform at least. Tabulated measurements of the operation of sylphons, metering and control mechanism, spring travel, etc., must be taken for future reference.

Testing on the Road

At least two experimental cars should be provided for the testing of each new model, no matter how few new features are brought out, as it would be an exceptional new model that did not contain at least a number of refinements in details. Ordinarily three cars had best be built, and two of them driven on the road by experienced professional experimental testers who are equipped in their specialty to adequately put the cars under every possible service and abuse the owners will likely give them; to report defects intelligently, and to suggest remedies and improvements from their intimate viewpoint.

The first car can be driven continuously, or twenty-four hours per day, by two or three shifts of two men each. During the pre-production period some of the drivers can be commercial testers studying the new model and getting prepared for testing it. The purpose of the two men on each shift is to expedite any work done on the car on the road, to divide up the driving work, help in heavy road difficulties, expedite caretaking work and that one may serve as a rescuer if he escapes injury in case of an accident. It is needless to say that poor or careless drivers will not be a good investment in experimental work. One of the two drivers in each shift serves as the captain of his shift and makes reports directly to the chief experimental tester, keeps up the data collected during his shift and opportunely co-operates with the engineering and experimental forces.

One of the results gained on the 24-hour car will be the effect of great distance, as 30,000 miles can be turned up normally in three months; another will be plenty of abuse administered, as the men get on a fine driving edge and can "slam her over the road" in good shape. Figuring an average driving season as 6,000 miles, the distance traveled will represent five years of service and the maximum of road abuse the car can receive. A car tested to this degree and found "all there," can hardly be compared to the one and two-season repairshop wrecks which are due to the low engineering standards of the makers.

At this stage the car should be completely taken down and inspected. It should have gone through the test without adjustments of motor bearings, cleaning of carbon, valve grinding, replacements and adjustments, and still be in fairly good running shape. With a few slight adjustments and cheap replacements, *i.e.*, a light overhauling, it should give a creditable performance and be ready for another long period of use.

The result of frequent warming and cooling, cold, garages, slow and irregular driving resulting possibly in rust, condensation, corrosion, freezing and the fine detail study cannot be got on the 24-hour or big mileage car, so the second car should be driven by a crew of two during the usual day of work and at times a little in the evenings. The sharpest talent should observe this car, and it should be tested all around the country and subjected to all possible conditions.

The third car should be kept about the shop to use for a model in fitting and measuring, etc., without holding up the active cars for that time-consuming work. This can be loaned to the engineers for their driving and study and also possibly used at times for some advance demonstrations to dealers. Side issues should not be allowed to conflict with experimental work. Using the experimental cars for personal and commercial services should not be tolerated. These things always consume more time than anticipated, distract from the work, destroy observation and spontaneous thought and interfere with road and weather opportunities. Routine matters should not be allowed to intrude on the work at any stage, as they spoil keenness of thought and originality.

After the rawest defects have been eliminated and the cars found safe to go out of the vicinity of the shops, every kind of roads and climate should be visited. The extremes of hot and cold weather should be experienced to see if the carbureting, cooling and other temperature-affected factors are right. Winter work in the north can be supplemented with warm weather driving in the south. Sand, gravel, dust, mud and snow roads should be sought to see if any kind of dirt gets in anywhere and does damage by clogging, chemical action or wear. To see if the clearances are good, the pulling is smooth, the brakes are adequate and all suspension, torque and running gear parts strong under abuse. Mountainous roads, rough and smooth roads, wet and dry roads should all be tried out in various combinations. A volume could be written on the fine details and abuses and the money that motor car companies have lost by lack of thoroughness in their testing-out work.

The Car's Initial Run

When the new car is first started out it should be run easily, well lubricated, and kept in good adjustment for a little while; then the severity of the work should be gradually increased in every way to a reasonable point, and finally the maximum of reasonable abuse and overload should be given. In this way the whole story of the weak features is obtained, whereas if the model was roughly handled from the start, and smashed, only one thing would be learned, and that is that it would not stand the maximum. As an abstract deductive method of analysis of the qualities of a car the practical maximum and minimum of everything must be considered. Two qualifying conditions creep in here: One is practical experimental judgment based on broad knowledge and experience and the ideal of the "Old One Horse Chaise" mechanical principle. Not that the climax in this ideal is looked for exactly, but that the standards in lubrication, adjusting, repairing, or the caretaking requirements are not such that a little neglect on the motorist's part is going to result in stalling him in the middle of a California desert or call on him to buy half of his car over again. For instance, if a ball or roller bearing is used in a part of the car likely to be neglected in some way, the chances of trouble to the motorist (which is always trouble to the manufacturer as well) will be much less perhaps than with a plain bearing that might seize and twist off a shaft, rip up a set of gears, or smash up a big casting. Such deep considerations make the fine automobile that connoisseurs speak of with admiration. The lack stamps the improvidential institutions that can hardly get their product to the shipping dock and be sure that something is not going to happen the next minute.

After the crudest of weak points have been remedied, the experimental work simmers down to the long-distance, long-time durability tests and the fine detail study under various climatic and road conditions and the unforeseen combinations of circumstances that are stumbled onto by accident.

About every 15,000 miles the car should be taken down and inspected thoroughly. When doing work upon parts that have fallen down in the test everything opened to view should be inspected, but it should always be kept in mind that frequent adjustments, tightening ups and minute attentions such as the average owner neglects should not be made, as valuable developments are apt to be lost. If the car is going to be a rattle trap, keeping the experimental and demonstrating cars tight is not going to help the motoring public's opinion in the least. It is better to find these things out at the factory and remedy them than to wait for the public to advertise the outfit as a junk pile.

Paper Work

An important aid in the work is the compiling of data and reports. These things are indispensable. On the cars, log books are kept of fuel, oil, water and tire consumption. Odometer readings, gage readings, acceleration readings, climatic and road conditions, are kept, tabulated for reference and comparison. Likewise, impressions of speed, power, noise and vibration are recorded. Thorough reports of the experimental work and data collected, as well as remedies and suggestions, must be promptly prepared and sent to the engineers and those helpfully concerned in the work. The reports are typewritten on a form handy for filing, and their delivery is carefully checked. An index is kept, which is compiled from the reports and data, and is available to all. The system compiles the story from the standpoint of problems under development, sub-assemblies and functions in the car. In this way the history of any development can be found quickly and without searching through a mountain of papers for little details. Insufficiently checked details and guesses should not be sent in unless time presses, and then they should be labeled as such.

In all experimental work the keynote must be thoroughness and adherence to actual operating results, and not pure deduction and theory. Some engineers are like the woman who dropped four cents on the street car floor and left the conductor to look for five. An engineer with a salesman's graces is a danger to the community. The work is impersonal. The experimental men must consider themselves as the company's and the purchasers' friend jointly, and not allow anything to be "put over" that is not up to the highest standards of the art. It is the duty of the management to see that the critics are not molested in any way by offended persons. Politics in the shop and underground bickerings caused by a neglect of the management to thoroughly supervise are very demoralizing to results in engineering work.

Truck Loading Devices Reduce Lost Time

Installation of Apparatus for Handling Loose or Bulky Material Cuts Labor and Increases Profits

By J. Edward Schipper

WHEREVER quantities of loose materials, or materials of tremendous bulk, have to be loaded into trucks the problem arises how this can be done so that the loading time and the expense of loading will be reduced to a minimum.

Every time an analysis is made of truck transportation cost, the length of time required for loading is found to be an important factor. Therefore, truck manufacturers, contractors and fleet owners are constantly endeavoring to cut down the time required to load or unload the vehicle and are giving every encouragement to the design and invention of devices which make this possible.

Loose material such as dirt, gravel, coal, ashes, etc., is most difficult to deal with. Solids, such as stone, bales of hay, bales of cotton, furniture, crates, etc., do not present as hard a problem, because they can be lifted on the loading platform and generally packed very easily by the driver and helper into the desired position. Where the articles handled are of miscellaneous size and shape, as in moving van service, manual labor has to be depended upon entirely, and for this reason a different basis of charge is generally used in this class of work. For handling the loose materials mentioned, however, a variety of devices are in use, and many of these are of exceptional value.

Dumping is the most common method of unloading loose material. Dumping bodies were employed to a considerable extent on horse-drawn vehicles before the motor truck came into common use. These early dumping bodies generally were manipulated by the driver, who inserted a crank on the squared end of the shaft and cranked the wagon body up to a dumping position. A train of gears gave the reduction necessary to enable one man to readily lift a loaded 2 or 3-ton wagon. This type of body was extensively employed for retail delivery of coal and is still in common use.

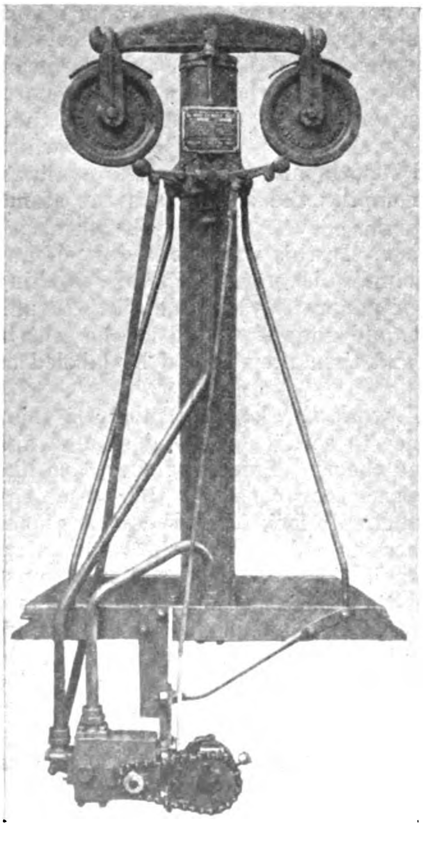
Hydraulic Hoists on Motor Trucks

In the case of the motor trucks the dump body is generally hoisted hydraulically. Owing to the presence of a gasoline engine on the truck, mechanical power is available for the hoist, and generally a take-off from the gearbox permits of the engine power to be used in operating the pump for a hydraulic hoist or in running any other unloading device which can be mounted upon the truck itself.

Hydraulic hoists are made in either vertical or slanting installations. With an hydraulic hoist it is important that the load be properly distributed so that when the outfit is installed on the chassis, the chassis is not called upon to take care of any undue strain; there must also be no undue strain on the hoist.

With a recent type of hydraulic hoist it is possible to dump a capacity load in about 15 sec. After the commodity is dumped it is not necessary to keep the truck at rest. The driver can start on his return trip and the body will of itself come back into position. This may appear on the surface to be a small item, but when figuring cost on a job, is is a saving of time such as this that makes the job profitable.

As compared with manual unloading or hand-operated gear trains for raising the dumping body, the hydraulic hoist is so far superior that it requires only a relatively



Left — Wood hydraulic hoist. Weight, 325 lb.; capacity, 3 tons.

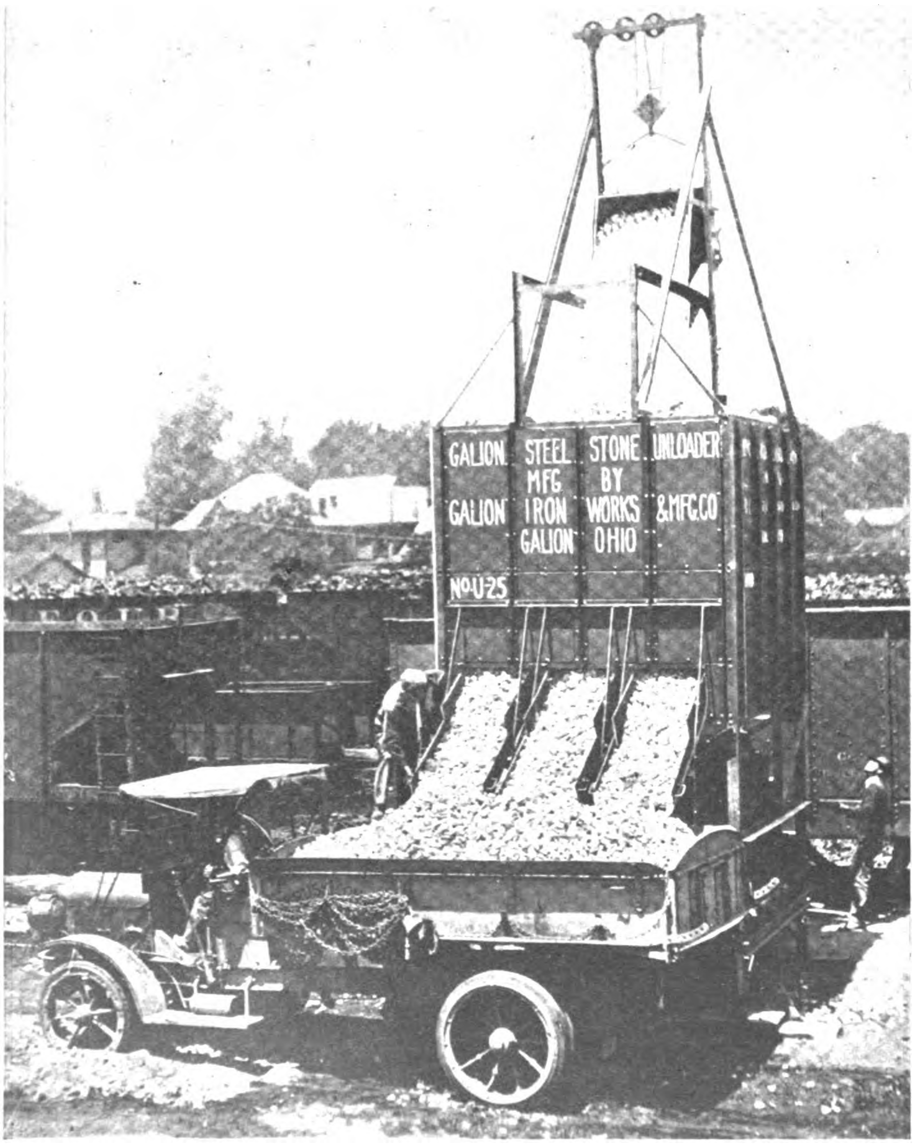
Haiss type of digging wagon loader, eliminating practically all hand shoveling

Dump body raised by power take-off on transmission system



Galion device for unloading hopper type freight cars into wagon by means of hoisting device, reservoir and chute

short time to pay for itself. This is realized by motor truck manufacturers who are indorsing the installation of the hydraulic hoist in combination with dump bodies.

An important factor in the success of a dumping body is the design of the tail gate. For instance, in road building, by the use of a restricted type of tail gate, sand or gravel can be spread along the road in any desired thickness while the truck is in motion. It is almost impossible to calculate in money, labor and time saved the value of this method. On the other hand, if the commodity is to be dumped all in one spot, it can be placed just where it is needed, and by the use of the vertical hoist the body can be quickly raised to the proper height. The angle to which the body must be raised has been worked out for various materials.

The hydraulic hoist for a 5-ton truck weighs approximately 500 lb. in the heavy-duty type; that is, a 500-lb. hydraulic hoist will have a capacity up to 7 tons. Such a hoist requires a space of about 15 in. between the body and the seat, if installed vertically, or from 18 to 20 in. if slanting. The lightest type of hydraulic hoist, designed for trucks up to 2-ton capacity, but capable of lifting up to 3 tons, weighs approximately 325 lb., and requires a space of $13\frac{1}{2}$ in. between the body and seat. On this type the body arms are outside the chasis frame.

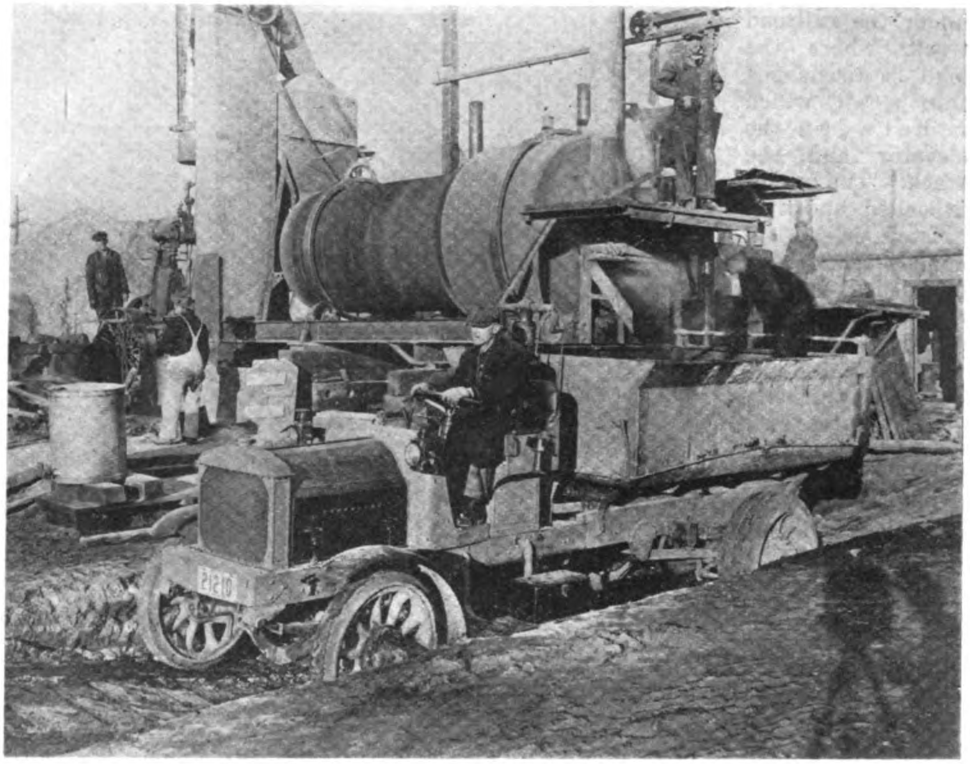
A Truck Crane

A very ingenious loading installation, which is used by Massachusetts municipalities for sewer cleaning, employs a truck crane with a fixed boom and a single drum for raising and lowering the clam bucket. This is operated by a direct take-off from the transmission gearset, and is mounted on an extension on the side of the truck frame, as illustrated. The clam bucket itself is opened and closed by compressed air, the air compressor which the installation comprises being driven from the transmission shaft. This arrangement can be made either automatic so that the clam bucket opens after it has been lowered, and closes when the hoist starts, or it can be made manually operated so that the opening and closing can be timed at the will of the operator. The crane swings the loaded bucket over the body of the truck, and it is dumped by the compressed-air system, which opens the clam bucket. Formerly the weighted tails were simply lowered and the cleaning operation performed by manual labor entirely.

In all loading of loose materials, particularly those which are delivered

to the loading point by freight car, it is highly desirable that gravity loading be used. Wherever it is feasible, the freight car should be brought up to an elevated track and dumped into overhead bins, from which the material can be withdrawn through some form of chute into the truck.

This method can be employed to advantage even in small-scale operations, because it not only eliminates manual labor, but after the material has been once delivered to the highest point by means of the rolling stock it requires no further power expenditure in handling it, except that required for opening and closing the chute doors.



Feeding from concrete mixer directly into truck, with ground dug away to permit clearance

The use of winches mounted on trucks for heavy work is practically a necessity. For instance, in telegraph and telephone pole installations, where the heavy pole has to be hauled into position and then lifted and lowered, the use of a winch effects a very material saving as compared with the old pike-pole method. Furthermore, the use of winches tends to obviate physical injury. Statistics show that truckmen compelled to lift heavy crates or other unwieldy bulks are more subject to hernia than any other class of men. For this reason alone the extensive use of lifting devices should be urged. A winch mounted on the truck platform will be found to give a wider range of utility to the truck body, particularly for contractors, who are apt to handle practically any class of work. Telephone and telegraph companies have found it necessary to maintain several trucks so equipped.

Sewer cleaning installation with power take-off from transmission and clam bucket, operated by compressed air

For handling such materials as coal, coke, stone, sand, fertilizer, and similar loose materials, from storage or cars, various types of portable loaders external to the truck itself can be employed to advantage. For instance, the continuous chain type, with closely spaced buckets, is very useful. The buckets pick up the load as the loader is pushed into the material, and are kept full by manual shoveling, if this is necessary. The buckets then deposit the load into a chute or hopper, from which it is fed into the truck. By the use of mechanical loaders of this type it is possible to cut the loading time from 15 to 20 min. down to 2 min. These figures are reported by the manufacturers of a device for unloading stone, sand, gravel, or other similar material, from a hopper-bottom car, carrying it to a bin, and loading it into a truck or wagon without the employment of any shovelers. It is figured that the cost for labor alone, loading stone out of a car into a wagon or truck, comes to about 15 cents per cubic yard when the work is done manually. With this type of loader it is claimed it will do this same work for about 2½ cents a cubic yard.

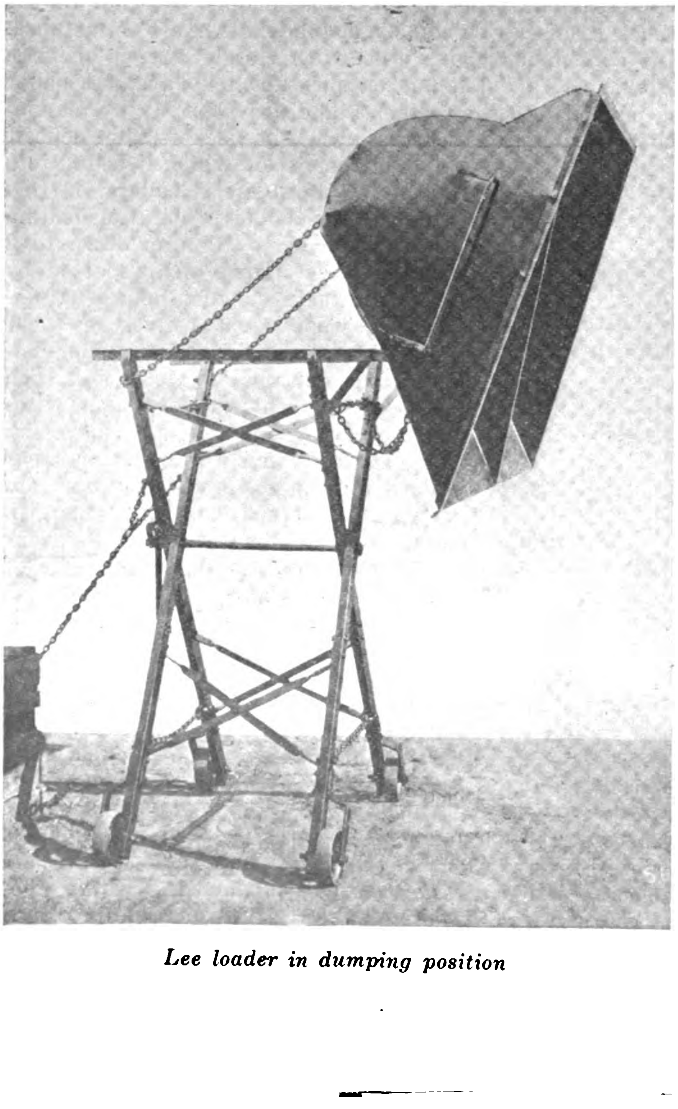
Machines of this kind are operated by one man, and as many as ten cars of a total weight of 500 tons can be moved in one day. The chief units in the construction of the loader are: frame, hoisting apparatus, bin, chute and pit, and the powerplant. The unloader is first located at a siding, and the cars are so moved that the hoppers or slides are over a chute placed

under the railroad track, where the load is discharged into a pit which is between the elevator and the track. The bucket is loaded, and then hoisted on an inclined track and emptied at the top of the track, into a hopper bin, from which it is discharged by gravity truck chutes into wagons, trucks or hauling cars. The drivers operate the chutes and load their wagons without delay or assistance.

Useful type of road body which can be loaded or dumped from the side

The elimination of hand shoveling is of supreme importance in saving time and money on work of this kind. As a matter of fact, it is almost impossible to get hand shovelers, because in summer there is so much other work to be had that men will not do this sort of work, and in winter conditions of frost make it practically impossible.

The manufacturer of a type of loader widely used compiled figures for comparison of costs in loading 5 cu. yd. of broken stone, coke, gravel, sand, and similar material, by hand and by a loader. His conclusion, based on cost of labor, time of use of truck, etc., was that the loading of a truck by hand cost \$1.94½ and by machine 45½c. The use of the loader almost exactly doubled the number of trips that could be made by the truck.



Lee loader in dumping position

British Standard Accumulator Rating

NO value for the capacity of an accumulator is of practical use unless it is also stated at what rate the current is generally assumed to be taken from the cells.

The following rating rule for accumulators used on automobiles for starting, lighting and ignition has been adopted by the Society of Motor Manufacturers and Traders (England):

"Accumulators shall have printed on their labels their actual capacity when discharged at a definite rate continuously, this rate being one twentieth of the capacity claimed. An interval of rest to be allowed, such interval not to take place until half the period of discharge has expired.

"In every case the discharge test is considered as being completed when the pressure in volts per cell has fallen to some pre-determined value, usually 1.8 volts per cell for the 10-hr. discharge and 1.85 volts for a 20-hr. discharge as an accumulator discharged at a very low and easy rate should not be allowed to fall to as low a point as would be safe at a higher rate of discharge."

During the past year this important subject of accumulator capacity has also been fully considered by the Portable Battery Makers' Section of the British Electrical and Allied Manufacturers' Association who have considered the matter from the point of view of electrical engineers dealing with accumulators used for every purpose, including automobiles.

A standard curve has been issued by them in which the percentage values for capacity at discharge rates varying from 1 to 20 hr. have been agreed upon and accepted by the principal manufacturers of portable accumulators.

This standard capacity curve having been considered by the Society of Motor Manufacturers and Traders through the Accessories and Components Committee, they fully appreciate the value of the work done in this connection, and agree that all figures for capacity based upon the 20-hr. figures in this B. E. A. M. A. curve are acceptable to them as true values for capacity at 20 hr. rate under rating.

THE Russell Mfg. Co., Middletown, Conn., has issued a booklet giving complete data of brake lining and clutch facing sizes used on different models of cars and trucks. The publication should be of particular use to garages and repair-shops.

Effects of Wrapping on the Strength of Struts

Found to Be of No Value When Additional Weight of Wrapping Is Considered—Bakelized Canvas Slightly Increases the Strength of Strut, But Cotton Tape Does Not

By T. R. C. Wilson*

THE wrapping, partial or entire, of certain airplane members such as struts or wing beams has been more or less commonly practised under the supposition that such wrapping aided in (1) increasing the strength at critical points, (2) holding the members together in case of partial failure, thus preventing sudden failures, and (3) keeping out moisture.

Wrapping has been advocated especially for cross-grained material in order to make available for airplane construction spiral-grained stock which would otherwise be rejected.

Extensive tests conducted by the Forest Products Laboratory of the Forest Service for the Air Service of the Army and the Bureau of Construction and Repair of the Navy on cross-grained, untapered spruce struts of the same outside dimensions covered with bakelized canvas gave the following results:

	(1) 2-Ply canvas covering (12 struts)		(2) 4-Ply canvas covering (12 struts)	
	Q	Q/W	Q	Q/W
Average	2922	619	2672	480
Maximum	3500	750	3200	580
Minimum	2425	532	2100	361

Q=Maximum or crippling load in pounds.
W=Weight of strut in pounds.

The deflections in inches of the struts which were tested to destruction were as follows:

	(3) 2-Ply canvas covering (3 struts)			(4) 4-Ply canvas covering (5 struts)		
	E.L.	T.	F.	E.L.	T.	F.
Average	2.0	4.9	6.3	1.7	6.1	7.8
Maximum	2.3	5.0	7.1	2.5	6.5	9.8
Minimum	1.7	4.8	5.0	2.1	5.5	6.3

E.L., T., and F. mean deflections at elastic limit, at first audible cracking of wood and at final failure of strut (rupture of canvas), respectively.

Four struts were tested to maximum load with the canvas on; the canvas was then removed and the struts again tested to maximum load. The average results and relative efficiency of different coverings follow:

	With canvas covering X			Canvas covering removed			Solid wooden struts of same dimensions as in X computed values		
Plies	Q	W	Q/W	Q	W	Q/W	Q	W	Q/W
2	3362	4.59	732	3012	3.53	852	3885	3.89	998
Per cent	100	100	100	90	77	116	115	85	136
4	2587	5.59	465	2145	3.43	636	3460	4.12	855
Per cent	100	100	100	83	61	137	134	74	184

Four struts were tested to maximum load with canvas full length after which the canvas was removed from the outer thirds of the length and the struts were again tested to maximum load.

The average results follow:

	Entire length canvas covered			All canvas removed from outer thirds of length		
Plies	Q	W	Q/W	Q	W	Q/W
2	2800	5.02	558	2590	4.30	603
Per cent	100	100	100	92	86	108
4	2300	5.58	414	2003	4.17	484
Per cent	100	100	100	87	74	117

Average results of tests of cross-grained Sitka spruce and Douglas fir struts (taped and untaped) follow:

Struts Wrapped with Cotton Tape and Given Three Coats of Dope.
10 *Pairs Sitka Spruce.*

	Weight (W) Lbs.	Maximum Load (Q) Lbs.	Q/W	Deflections At E.L. Ins.	Deflections At T. Ins.	Load at T. Lbs.
Taped	3.49	1262	362	2.1	6.2	934
Untaped	3.24	1276	394	2.0	6.4	910

Struts Given Two Coats of Wood Filler, Wrapped with Cotton Tape and Given Four Coats of Dope.
10 *Pairs Sitka Spruce*

	Weight (W) Lbs.	Maximum Load (Q) Lbs.	Q/W	Deflections At E.L. Ins.	Deflections At T. Ins.	Load at T. Lbs.
Taped	3.37	1197	355	2.5	3.9	993
Untaped	3.25	1285	395	2.1	5.2	1046

10 *Pairs Douglas Fir.*

	Weight (W) Lbs.	Maximum Load (Q) Lbs.	Q/W	Deflections At E.L. Ins.	Deflections At T. Ins.	Load at T. Lbs.
Taped	3.94	1480	375	2.8	5.0	1262
Untaped	3.63	1406	387	2.2	5.4	1121

E.L.= Elastic limit. T.= Tension failure.

These struts were of the tapered type used in the J-I training plane. All had cross grain of greater or less degree. Each taped strut was cut from alongside an untaped one. Before taping all struts were the same size.

The conclusions from all tests are as follows:

The addition of bakelized canvas to cross-grained struts, (1) increases the load somewhat but decreases the load per unit weight, and (2) increases the deflection and work to final failure and hence the shock-resisting capacity.

Wrapping cross-grained struts with cotton tape according to standard methods has no appreciable effect on their strength properties. It is doubtful if any other methods of wrapping such as cording would increase the strength properties very greatly. There is also the probability that any wrapping or covering will be loosened by weather changes.

It is believed that wrapping is of less value than the same *volume* of wood, and since the wrapping is likely to be heavier than wood it is of still less value compared to the same *weight* of wood.

*Engineer in Forest Products.

Landing Fields for Commercial Aviation

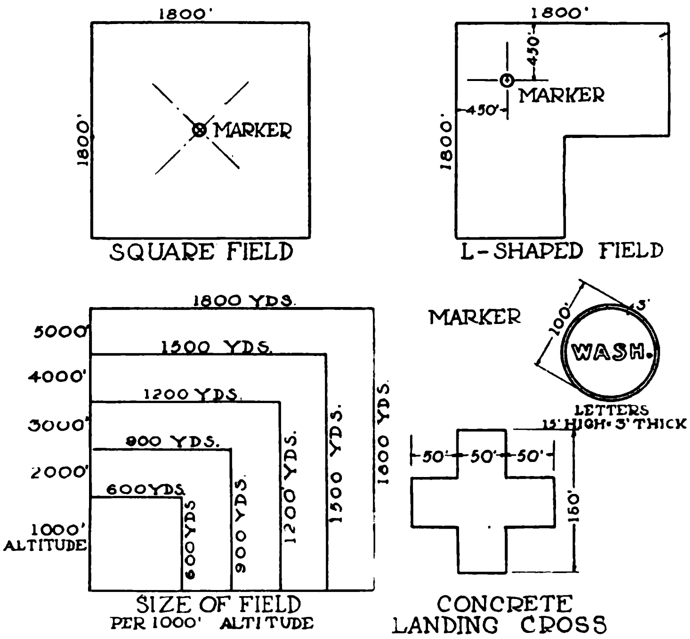
Some Considerations Entering Into Their Location and Design, as Determined by Army Aircraft Officials

According to army and other Government officials, landing fields are of the highest importance when it is attempted to establish commercial aviation routes, and the many elements that enter into their construction must be fully considered. Although no complete and comprehensive analysis has yet been made of all the factors that should be taken into account, some reports have been made on the subject and rules and regulations established by the War Department.

Because of the thinner atmosphere in districts located at a relatively high altitude, it is necessary to make the fields in such districts of greater length, to make it possible for the machine to attain a greater speed within the length of the field and thus insure the same rising power. For determining the necessary length of the field the War Department has developed a formula by which the length of the field necessary at sea level is multiplied by the ratio of the average weight of dry air (in pounds per cubic foot) at sea level to the average weight of dry air at the altitude considered. This gives the required length of the field at the altitude in question. The accompanying chart and table illustrate this method.

The height of surrounding country, the accessibility of the field from the port of call, the character of the soil and the prevailing winds are other important considerations. A landing field properly constructed according to the War Department specifications published herewith must have the point of landing at least 1200 ft. from the nearest obstacle 100 ft. high, 500 ft. from the nearest obstacle 60 ft. high, etc., including as obstacles trees, buildings or other construction, and hills.

To mark the fields so they can be distinctly located from great heights the army uses either a concrete landing cross measuring 150 ft. in each direction, or a circle 100 ft. in diameter with an outer ring 3 ft. wide and with letters 15 ft. long and 3 ft. thick.



Landing field length factor plotted against altitude

Where fields are built in sections that suffer from considerable wet weather or frost, sand foundations should be used to prevent either mud or rough frozen ground.

Data for Use in Calculating Necessary Length of Landing Fields

Altitude in Feet	ρ	l_0/l	$\sqrt{\frac{l_0}{l}}$
0	.0768	1.00	1.00
2,000	.0730	1.052	1.026
4,000	.0685	1.121	1.058
6,000	.0639	1.201	1.094
8,000	.0601	1.278	1.131
10,000	.0565	1.359	1.165
12,000	.0531	1.446	1.203
14,000	.0497	1.546	1.243
16,000	.0467	1.543	1.283
18,000	.0439	1.748	
20,000	.0412	1.863	

ρ = average weight of dry air in lb. per cu. ft

ρ_0 = weight of dry air in lb. per cu. ft. at sea level.

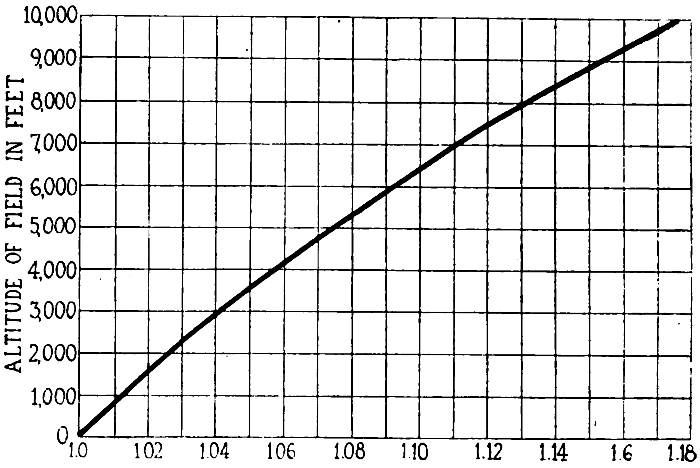
From formula.

$$L = K_y A v^2 = C \frac{1}{g} A v^2$$

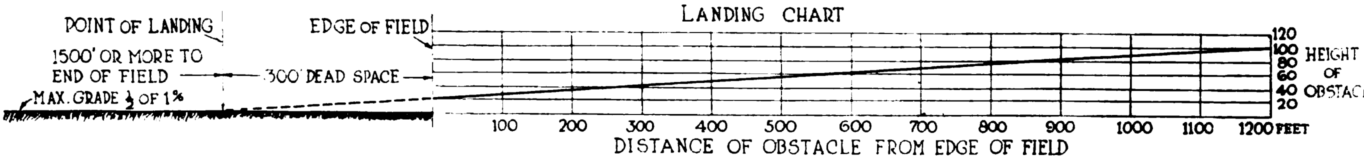
$$V = \sqrt{\frac{g W}{C \rho A}} = \sqrt{\frac{\text{const.}}{l}}$$

L = lift = W = weight

Since l is the only variable the velocity varies as $\sqrt{\frac{l_0}{l}}$



$\sqrt{\frac{l_0}{l}}$



Specifications for landing fields

Emergency fields, which do not have to be so complete as the permanent landing fields, should be particularly numerous in hilly country where it would be difficult to effect a landing. To insure absolute safety, the fields should not be further apart than twelve times the service ceiling of the airplane used. It is generally estimated that an airplane can make a forced descent six times as long as its service ceiling. For example, the Curtiss planes used in the air mail service have a ceiling of 1 mile. In case of trouble they can glide down over a distance equal to six times their ceiling, or 6 miles, and consequently if emergency fields are located 12 miles apart, the planes, when forced to land, are always able to reach a field.

Fields of this character, being used only in emergencies, need not be given the attention of permanent fields and can be considerably smaller. An airplane can land on a field 500 ft. long, although it might not be able to rise from it.

In deciding upon the location of a hangar on a field, the direction of the prevailing high winds must be studied. Properly arranged, a hangar will serve to take the brunt of the usual prevailing winds and act as a protection to the field and to the airplanes landing on it. At the same time the hangar cannot be built so that the winds will blow across the entrance.

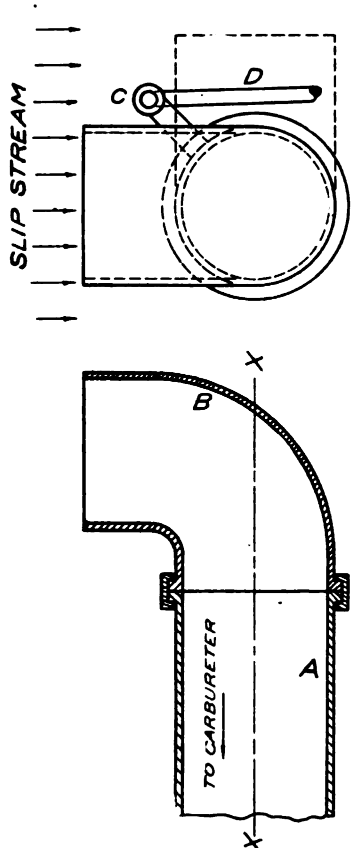
There is considerable danger of injury to planes leaving or entering a hangar if the entrance is not shielded and so built that the winds strike the back of the building instead of across the doors.

A Suggested Modification for Liberty Carbureter Air Intake

By C. V. Elliott

In the March, 20, 1919, issue of AUTOMOTIVE INDUSTRIES two views were shown of the air intake used on the Liberty aircraft engine. The article states that the intake pipe is cut off at an angle so that pressure may be produced by the propeller slip stream.

Some time ago the writer experimented upon the effects of a stream of air passing the end of a small tube when the tube axis was at different angles with the direction of the air current. The tube was connected to a U tube manometer containing water which indicated any suction or pressure that was produced at the end of the tube. If these experiments of mine are comparable with the conditions existing at the carbureter intake, it would seem that the angle at which the air intake for the Liberty aircraft engine is cut off is about the proper angle to reduce the effect of the propeller slip stream to zero.



Proposed modification of Liberty carbureter air intake.

This at once suggests a modification of the design by which it might be possible to increase the power of the engine at high altitudes and at the same time partly compensate for the increased richness of the carbureter mixture at high altitudes. Some of your readers who may have the facilities might be interested in trying the design here illustrated and explained.

In the illustration, *A* represents the vertical carbureter intake pipe to the top of which is attached the elbow *B*. *B* is fastened to *A* in such a manner that it may be rotated about the vertical axis *X-X*. *B* has a lever arm *C* attached to it so it can be rotated by a rod *D* running to the dash.

When the opening of the elbow squarely faces the slip stream, the total air pressure in the intake would be the sum of the atmospheric pressure plus the pressure equivalent of the slip stream velocity. With the elbow turned 90 deg. from facing the stream, a suction instead of an impact would be produced in the intake, the value of which varies with the velocity. At some position intermediate between these two, the slip stream velocity would have no effect upon the pressure in the intake.

The probable effect upon the mixture would be to make it leaner when the elbow faces the slip stream and richer when at a right angle. If the carbureter were adjusted to give the correct mixture with the elbow at a right angle with the slip stream and then turned facing it, it should partly compensate for the effect of decreased air pressure at high altitude. With the elbow facing the stream, it should also be possible to get an increased weight of mixture into the cylinders, hence, more power.

If anyone should try this or has already tried it, the writer would be pleased to learn of the results.—C. V. ELLIOTT, *Instructor in Mechanical Engineering, Louisiana State University.*

Carburetion of Low Grade Fuels

(*Continued from page* 1259)

changed a number of manifolds along these lines, and in every case there has been a decided increase in power and fuel economy; in some cases both were increased as much as 25 per cent.

On large engines, where the manifolds are of considerable length, and especially on heavy duty marine engines, the distance the fuel has to travel becomes a serious factor, and it is well to consider the advisability of using a carbureter for each cylinder or for each pair of cylinders. In such cases a side outlet carbureter, where the fuel passes from the mixing chamber to the engine cylinders by the shortest possible path, is the most effective.

It is also essential to make a close study of the mixture velocity in the mixture passages. No doubt there are designers with plenty of experience who can estimate very closely the necessary velocity, but for truck, tractor or marine engines, in which most of the low grade fuel is used, it is advisable to make up several manifolds giving different velocities, and thus develop the correct size experimentally. This applies also to a certain extent to automobile types. It is the writer's opinion that for most of the work above mentioned, a limited full load speed is desired, and after all other parts of the design have been settled, it is well to reduce the manifold area until it just begins to affect the maximum power. This will unquestionably produce the best results.

ONE of the noteworthy consequences of the war, according to *Metall und Erz*, is the great increase in the output of wolfram (tungsten). Before the war the whole world production did not exceed 10,000 tons annually. The present output is at least double that quantity. An approximate estimate gives: Portugal, Spain, France and Great Britain, 2500 to 2800 tons; North America, 6000 tons; South America, 3000 to 3500 tons; India, Siam, the Malay States and Australia, 5500 to 6000 tons; China and Japan, with Indo-China, 800 to 120 tons.

The FORVM

Ensign Heavy Fuel Apparatus

By O. H. Ensign

A CARBURETOR with an inherent correct-mixture characteristic dependent upon the principle of design (rather than on experimental or scientific development by combining certain compensating elements) is especially valuable with low-grade fuels. The carburetors described herein fulfill these conditions. The basic design of these carburetors is shown in Fig. 1. Fig. 2 shows a horizontal section through this vortex mixing chamber. The air enters the metering chamber X tangentially and flows downward to the outlet K of the chamber, following a helical path. The air inlet is of the same size as the engine manifold (the nominal carburetor size) and the velocity is nowhere higher than in the manifold. The pressure drop at the center of the vortex mixing chamber X is the result of centrifugal action, plus the small entering velocity head. With air only, this pressure drop at all speeds is directly proportional to the velocity head in the air horn or manifold, averaging about five and a half times that head.

When operating normally, the fuel drawn in at the center of X is thrown by centrifugal force through the revolving air and attains its maximum velocity near the rim of X. In so doing it absorbs from the air the energy necessary to attain this velocity, thereby causing a drop in the whirling speed of the air, which in turn acts to reduce the suction on the fuel applied through the suction outlet D. In other words, we have a centrifugal pump with an air impeller operating under suction lift only, against a restricted orifice, but this pump is flexibly impelled and slows down with the added load of fuel with each increment of added motor load, so that there is an inherent tendency to thin the mixture as the load increases, instead of a tendency to enrich it. The mixture characteristic can be changed by the operator only with reference to the general fuel-to-air ratio, but not for any particular speeds and loads.

Vaporization of the lighter constituents of the fuel also causes an added drop of suction at D, as their expansion partially eliminates the vacuum, so that the more volatile the fuel, the less will be used. The more you heat the mixture by means of hot air and increase the vaporization, the less fuel will be used. In other words, the better adapted the fuel is for economical use in the motor, the less of it the carburetor will deliver, and this applies throughout a wide range of temperature. There is no need of adjustment for temperature changes, but adjustment will be required when changing from one fuel to another of far different volatility. This characteristic makes hot air the most effective method of heating. The rate of revolutions about the center of the mixing chamber X reaches 15,000 per minute in some installations. The heavy particles of fuel will be thrown to the outer wall and brought into the fresh air stream repeatedly, thus "aerating" the fuel to the maximum, if such a term can be used, and those heaviest fractions which reach the holes J at full load will pass through them under an atomizing pressure of about one-fourth of the total pressure drop through the mixing chamber, which may reach 30 in. of water when the proper size carburetor is used. Hot air in this mixing chamber aids materially, because the reduction of viscosity allows better breaking up of the fuel. At low throttle, all the heavy particles will be carried through the by-pass tube Z and ejected above the throttle at O. The natural mixture characteristic of this carburetor on modern gasoline is from 16 to 1 by weight at no load to about 17 to 1 at full load, with a straight line mixture inherently produced between these two points under all conditions of operation. The unbalanced butterfly E is used only for automobile work, when manifold conditions make it difficult to get extremely low idling. However, on an ordinarily geared machine at 7 to 10 m.p.h., this unbalanced butterfly lies horizontally and offers no resistance. It is not in any sense a choke and does not affect the pressure on the mixture at any time more than ⅛ in. of water. With this metering characteristic and this tremendous aeration of the fuel, it is naturally a low grade fuel instrument, and 90 per cent of the factory output of the Ensign Carburetor Co. has been for other fuels than gasoline—mostly kerosene.

Fig. 3 illustrates the side outlet carburetor in this type, for use with block motors with or without integral manifold.

With this straight line mixture and the manifold construction outlined above, combined with the proper application of hot air, there is not as much risk from pre-ignition as there would be where there is a possibility of a stratified mixture and poor distribution.

To still further eliminate the difficulties arising from starting and handling of low grade fuels, especially kerosene and similar products, the Ensign fuel converter, shown in Fig. 4, has been developed and it is believed to have reached a stage of perfection. This instrument uses the same metering system but adds a gas producer, a priming chamber and a thermostat.

Under all conditions of operation the heavy fractions pass through the fire screen U by gravity, over the distributer C into the combustion chamber Q and are there ignited by the spark plug which is in series with one of the cylinder spark plugs, or may be supplied from a special distributer. There is formed a continuous downward flame, and partial combustion takes place, because the suction through the gas flue Z puts the flame out before combustion is complete, delivering a fixed inflammable gas above the throttle. The heat developed by the gasification of the heavy particles of fuel causes a rise in temperature of the floor of the mixture passage L, the walls of the gas flue Z and adjacent parts, vaporizing the lighter particles of fuel, so that the resulting mixture is composed of vaporized fuel, free carbon, fixed gas, a certain percentage of inert gases and steam. The throttle is provided with a notch O, into which a square plug M, operated by the thermostat capsule N, is projected by action of the heated mixture, which is forced to flow about the capsule N, thereby regulating the opening of the notch O to control the draft through the flue Z when the motor is idling, and thus regulate the idling temperature.

With the throttle wide open the draft through the flue Z is an induced draft, brought about by the elbow of the main mixture passage, the obstruction offered by Z, etc. The idling temperature is limited to something under 235 deg.; the load temperature varies according to the motor and other conditions, from 235 deg. down to 160 deg. In other words, the temperature is

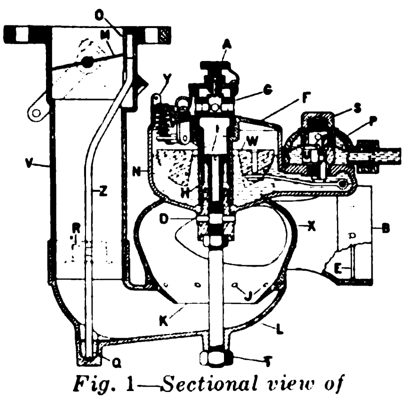


Fig. 1—Sectional view of Ensign carburetor

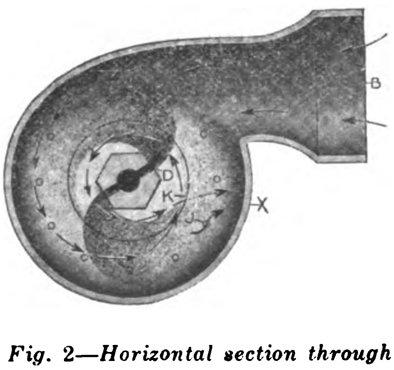

Fig. 2—Horizontal section through vortex mixing chamber

highest with the lightest load and lowest with the heaviest load. The by-pass V takes air relatively free from the heavy fuel mixture, out of the upper part of the mixture passage L, and compensates for the tendency of a large portion of the fuel to flow into the fire box when starting cold or in cold weather. Also, it furnishes relatively clean air to maintain a higher rate of combustion under those conditions, while in warm weather the heat travels up into the mixing chamber X, and some of the lighter particles of the fuel will be vaporized and pass through V, smothering the fire. Thus the apparatus inherently compensates, to a great degree, for changes in temperature and changes in the end points of the fuel.

It is started by means of a gasoline primer in the chamber E. At the top of this chamber is a large hole which overflows when priming cold, and a puddle of gasoline will form under Z. With the throttle closed and the plug M withdrawn, the engine is sure to get a good mixture for starting. Gasoline continues to feed, at a reduced rate, for a short time, until the cup E is empty. However, the instant a spark occurs in the combustion chamber, there are formed a fixed gas and heated vapors that will operate the motor in the coldest weather. Starts have been made at 16 deg. below zero, which permitted of putting the motor to work immediately, and within the short distance of a city block full power on kerosene was obtained. It starts on a kerosene prime from D when hot and a few drops of gasoline from F when warm. The inverted cone B is of a refractory cement, practically indestructible. The small threaded rod standing in the flue Z has a vertical movement of about 1/16 in. and under the suction and the jar of the road, moves around in the flue Z, removing any carbon which may collect in the flue.

This offers an instrument for handling any water white fuel from gasoline through to kerosene, with no change in the instrument other than adjustments of sleeve G, with a change in the viscosity of the fuel, except that in warm weather when running on gasoline the spark plug in the combustion chamber should be short circuited. The instrument then becomes a gasoline carburetor.

With this instrument ideal manifolds are not necessary, but are an advantage. It can be started to work immediately, which is more than can be said of present gasoline equipments, when cold weather conditions are considered.

The pressure of a certain percentage of inert gases (carbon dioxide, carbon monoxide and methane) in the mixture will obviate pre-ignition under compressions which with any other method of heating kerosene would cause serious trouble.

When operating at extremely low speeds under small throttle, the thermal value of the mixture is lowered, because a very large percentage of all the fuel is drawn through the fire box and converted into fixed gases, but as the throttle is opened up, the thermal value of the mixture increases. The all-around average result on many commercial installations indicates an average of one-third less kerosene used than with gasoline. This, of course, is due to better distribution to all cylinders and a uniform performance on a thin mixture, as well as to a slightly increased thermal value of the fuel used. Some block tests have been made in which the horsepower exceeded that obtained on cold gasoline, under the same conditions. This was undoubtedly due to the fact that the distribution to the cylinders was very materially improved.

An entire change of the character of the mixture occurs with extreme changes of atmospheric temperature, for in extremely cold weather, no doubt, a very large portion of the fuel passes through the fire box all the time, because it simply is metered by the chamber X and not broken up to any extent, and probably this fuel, passing through the fire box, is cracked to a certain degree to some lighter fractions, as it has to pass through the flame zone. Also, during cold weather a very persistent fog is created by these vapors of fuel, which pass through the flame zone and are delivered above the throttle, by contact with the colder mixture, going around the outside of the flue Z.

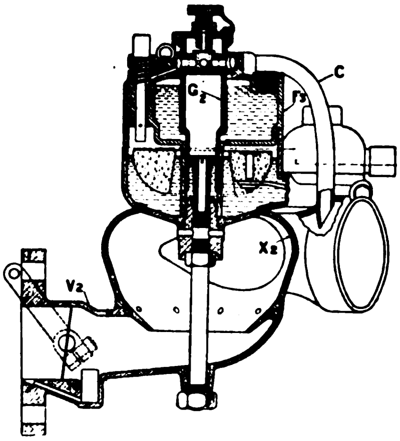

Fig. 3—Side outlet carburetor for use with block motors

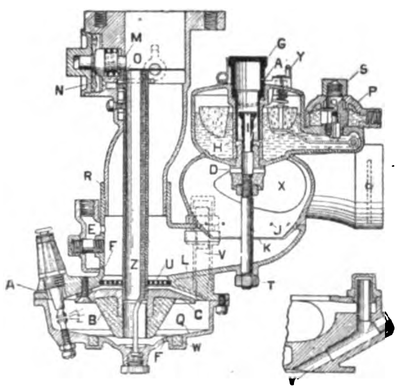

Fig. 4—Ensign fuel converter

The apparatus has been in continuous operation for over two years. Throughout this period the motor was in better condition, with less repairs than with any other method of carburetion, and within the last six months it has been possible to operate without unusual attention being given the converter.

—

Odd Ways of Starting Gas Engines

By Jack Hiscock

NOT every motorist as he presses his starter pedal, stops to think how fortunate he is that the process of cranking the engine has been so simplified for him. Electric starters were developed because the old method of cranking by hand proved intolerable. Yet, hand starting of an automobile engine is child's play compared with the methods necessary to start some other types of engines.

When a tractioneer starts the engine of his big caterpillar, he fits a bar into one of a series of sockets in the engine's flywheel and rocks the engine up to compression. No one can spin these monsters. Rarely can they be rocked past compression, but are usually rocked backward up to compression, where, thanks to generous priming and a hot spark, they usually fire and the wielder of the pinch-bar pulls it from the darting socket hastily.

The petty officer on a submarine chaser relies upon compressed air to start his unwieldy engines. He, too, must prime copiously and has the additional responsibility of an auxiliary engine, hand-started to pump the air.

A most picturesque but risky method is ordinarily used to start airplane engines. The mechanic shouts "Off" as he approaches the propeller and is answered in kind by the pilot at the switch. He then spins the great wooden blades by hand to charge the cylinders with gas. Having worked up a warm perspiration, even on the frostiest mornings, he springs clear and shouts "Contact!" The pilot indicates that he has closed the switch by repeating the signal and the mechanic once more approaches the propeller. Gingerly this time, however. With a single swift motion he twirls the blade through an arc of more than 90 deg. and steps quickly away from and to the side of the murderous whirling stick.

A 150-hp. engine is about all anyone but a Samson can swing. When heavier engines, culminating in the 400-hp. Liberty, made their appearance, new methods had to be devised. At first the blade was pulled over compression by running past it and giving it a smart pull in passing. Sometimes two men with hands joined were required. As many as three were required to do the preliminary "winding up" or charging. Owing to the weight and complication, electric starters were not considered seriously, but an auxiliary magneto was made use of to produce a shower of sparks in the cylinder under compression.—JACK HISCOCK, *Splitdorf Electrical Co.*

Engineering Comment on Pertinent Questions of Design

(*Continued from page* 1255)

close as possible to the cylinder walls and have arranged the gas passages as free from bends as possible. This has given very gratifying results, even in the lower speed range.

I am not in favor of a piston speed above 1500 to 1600 ft. per minute on account of the lack of time necessary to vaporize the fuel at higher speeds. With low-grade fuel the time available for vaporizing, compressing, and exploding it is too limited to permit combustion of the full charge, and necessarily part of the gas stays in the cylinders in the raw state and filters into the crankcase by the piston rings, thereby cutting the quality of the oil and causing bearing troubles.

The Pistons

I think the hour-glass type of piston and the broken wall piston will have a restricted use, as, for instance, in flying machine motors or racing motors, but I cannot see how anything but the full cylindrical type can be used in the everyday motor. Everyone must realize that in the gas motor, the piston is not quite as well guided as in the steam engine and, therefore, the bearing of the piston into the cylinders must be made long enough to insure a perfect joint and a compression chamber absolutely tight. As the film of oil, which is between the wall of the pistons and the cylinder, plays a great part in gaining that object, it must not be broken in the length of the piston in order to have the greatest efficiency. There is also the trouble known as piston slap, and this can be avoided only with a piston bearing as long as possible and unbroken. In fact, I think that we could have better motors to-day if we would lengthen our pistons slightly instead of trying to shorten them. At least, it would give the motors a great deal longer life.

My experiments with the different types of aluminum pistons have not convinced me yet that it is the proper piston to use in a motor. Neither the heavy type nor the die cast aluminum piston has been proved satisfactory, and especially since, with the fuel we are using, we must prevent, by all possible means, the passing of the raw gas by the pistons into the crankcase, the aluminum piston is certainly at a great disadvantage as compared with the cast-iron piston. For limited service in specially built motors for racing cars and flying machines, I consider the aluminum piston a necessity, but for continuous and heavy service, nothing has yet appeared to take the place of a well-designed cast-iron piston.

I cannot see any chance for a radical change in the transmission. I think that a great deal of the noise caused by the meshing of the first and second speed gears could be avoided if the transmissions were designed with wider and heavier bearings, also with heavier shafts, avoiding the deflection of the shafts under load. The practice of making secondary shaft gears and their shaft revolve together on two outer bearings should be abandoned, because the load is applied only on one point and has a tendency to bend the shaft and, of course, makes the gears run out of true, thus causing some noise. The best plan is to have the countershaft gears in one unit revolving on a fixed heavy shaft. This tends to eliminate any chance of deflection and to distribute the load evenly along the full length of the shaft. The gears will run smoothly and noise will be eliminated.

Rear Axles

I do not think that the rear axles are too strong on any car. Some of them might be too heavy and some better design, no doubt, can be evolved which would reduce the weight and make a better axle. But in my opinion the rear axle of the average car could be made stronger and better by using larger bearings, also a higher grade of steel for the shafts, and a special heat treatment of the steel tubing, permitting the use of a lighter section with a high elastic limit. An electrical treatment of steel tubing has been devised recently which increases the elastic limit of the tubing by 100 per cent and, no doubt, this could be used in making a rear axle stronger and lighter at the same time.

In my opinion the great majority of cars on the market have very poor brakes. The reason, I believe, is that we apply the braking power on the slowly revolving rear wheels with less effect than if we applied the power to the transmission shaft revolving at a high speed. No doubt the reason for putting the brakes on the rear wheels has been that most of the automobile plants of this country are located in flat country, where designers do not have the opportunity of trying the cars on mountain grades. If some of the automobile factories were located near the Rocky Mountains, no doubt we would have better brakes because, in testing the cars, the engineers would find that the present brakes would not take a car down a grade seven or eight miles long without burning the motor and having to brake with the motor. Foreign cars are better than ours in this respect, for most of them are used on mountain roads, and as far back as 15 years ago their designers had studied the brake question and had transmissions with the brake drum flanged to permit the cooling of the drum by water. —E. Planche, Chief Engineer Dort Motor Car Co.

By John Wilkinson

Super-induction charge for the purpose of ramming an excess charge in the combustion chamber is utterly futile. It makes the car heavier, it consumes more gasoline per mile, it increases the cost and the complication. The economy is less because super-induction, on account of the increased mean temperature, cannot be used with as high compression as is used in the ordinary four-cycle engine. It, therefore, follows that the thermal efficiency will be lower. Also, on account of the higher mean temperature, more radiator will be required, the exhaust pressure will be higher and more muffler will be required; and, too, on account of the same high mean temperature better exhaust valves will be required. Added to this will be the complication of a means for super-induction.

For a given horsepower, although the mean effective pressure is raised, there is no reason to look for more horsepower per pound of weight. Therefore, as first stated, the automobile will be heavier, more costly and less efficient.

In regard to pistons I can see no field for heavy aluminum pistons in small size cylinders, because weight limits the speed. Die-cast pistons are very successful in themselves.

The Riccardo type, with guiding and sealing elements. may find a considerable field in stationary practice, but in automobile practice, where high speed and light weight are necessary, this type would seem to be impossible.

From transmissions he has seen the writer believes it is quite possible that within a few years such improvements will be made in grinding gears that we may expect to get a commercially satisfactory transmission. I have already seen some special transmissions which are so much better than the average that they would seem to be good enough if used as a standard.

Most all rear axles are too heavy and when the designers appreciate the disadvantages of this weight, they will have no trouble in producing a reasonable weight axle.

I am a thorough believer in the transmission brake as a foot brake for general service. The advantages in having one brake on the transmission and one brake on the rear wheels, so as to remove as much weight from the rear axle as possible, should be evident. This results in better diffusion of the heat in braking under severe conditions and furnishes a foot brake for general service which, when applied quickly under high speed, will not throw the car into the ditch.—John Wilkinson, Vice-President H. H. Franklin Mfg. Co.

Tractor Design Problems

By L. L. Cass

I do not think it logical to restrict intake passages to govern the performance of a tractor engine. Why build for power that cannot be used? The logical method would be to apply to a tractor an engine with 25 per cent surplus power, which would be avaliable in extreme conditions. Make an engine as efficient as possible and so powerful that, except under extreme conditions, there is always reserve power. When this is done, engine trouble will be reduced to a minimum.

Comparative results obtained with both splash and pressure lubrication, which I have observed personally, prove conclusively to me that pressure lubrication is absolutely necessary, the most practical pressure being 25 to 30 lb. at 1000 r.p.m. of the engine. Positive application of lubricant is the only way to be sure of accomplishing the desired results.

The wise tractor owner is the one who insists upon using gasoline instead of kerosene. Many good kerosene burning equipments are on the market, but with the best of them there is found to be considerable crankcase dilution, more so than with gasoline. While kerosene is cheaper than gasoline, lubricating oil must be changed more often, bearings must be watched more closely and better performance can be obtained by the use of gasoline.—L. L. Cass, Chief Engineer, Parrett Tractor Co.

By H. L. Horning

If the passages are restricted for the purpose of eliminating the governor, I do not think it will be satisfactory. The farmer demands a tractor with a governor. All engines have restricted intake passages whether they are served by a governor or not. No doubt these restricted intake passages save many engines from untimely destruction.

I think pressure lubrication will be satisfactory when it is better understood by the manufacturer and the user. At present the splash is the most satisfactory system. Nothing can take the place of design and good workmanship in bearings, nor can lubricating oil be expected to cover the defects of a bad system of lubrication.

The common method of lubrication is splash, in which the level is established by overflow dams. Another form, and the most reliable, is the splash system in which the oil level in deep troughs is correctly maintained, irrespective of the inclination of the engine. The oil pump capacity in pumping the oil into the troughs is just equal to the capacity of the scoops to throw the oil out. Inasmuch as the oil pump capacity varies with the speed of the engine, and the rod scoop capacity the same, the level of the oil is constant.

Force feed through a hollow crankshaft is a well-known and high-class system. It has not been widely adopted because of the difficulties with leakage of oil under pressure, both past the piston and rings and at the crankshaft, and because of the unusual workmanship required for the pressure maintenance. In both the above mentioned systems old oil is pumped over and over, and this leads to bearing troubles.

Lubricating oil is little understood even by the refiners. Most tractor oil is so loaded with the heavier portions that under high pressure and temperature under the piston heads and walls it breaks into lighter oils, carbon and tars. Added to this, many engines suffer from dirt, dust and sand which enter either at the carbureter or breather. Taken together, the oil in the crankcase of an engine in use for a month, with either the splash or common force-feed systems, is usually a bad mixture and entirely unfit for lubrication uses.

With the force-feed system, unusual care must be taken to strain and settle all grit or dirt out of the oil, or it will cause unusual damage to journals and bearings. No such care is necessary with the splash system, as it seems to develop the least difficulties with dirty oils. With clean oil, well filtered and of good body, the force-feed system works exceedingly well so long as the bearings are in good adjustment. A surplus capacity of oil must be available at all times, so one or more loose bearings will not starve other bearings. Unusually good piston and cylinder fit must prevent overoiling of cylinders when rod bearings are loose.

The ideal system, if expense and care are no object, is the force, feed of fresh oil to crankshaft bearings and cylinder in exact quantities. So far as results are concerned on the surfaces, bearings lubricated by this method are not only the most economical in oil consumed, but also insure the longest life to both journals and bearing surfaces.

This brings us to the effect of heavy fuel on the bearings of tractor engines. Incomplete vaporization leaves heavy fuel unburned, incompletely burned and decomposed on the walls of the cylinder and combustion chamber. Under the action of high heat the fluid residue flows down the cylinder and past the rings, through the oil drain holes so commonly used, into the crankcase.

The products of complete and incomplete combustion found in crankcase oil range in hydrocarbons from formaldehyde to sugars. They include acetone, alcohols, sorghums, formic acid and a list of disinfectants varying in constitution according to the circumstances of combustion. This mixture, taken together with the solid contents mentioned above, constitutes about the worst lubricant a cylinder and bearings could have. The lower crankcase is the catchbasin for the by-products of imperfect combustion process. It is the main sewer for decomposing body fillers of our poorly compounded lubricating oils. It is the settling basin for steel, iron and bearing particles which slough off into the lubricants, and the crankcase with its oilpan forms the dustpan of the self-appointed air cleaner which duty every engine takes upon itself.

Taken from an unbiased standpoint, have engineers in tractor engines of to-day finally arrived at about the worst lubricating conditions possible? Is there any device which would permit more fuel to get into the lubricant than our present design of oil scraper piston?

The man was a great philosopher who said, "Tractor engines work in spite of the designers and users."

The heavy fuel and by-products of combustion appear

to have bad effects on steel journals and bearing materials. In England some practical men, and engineers as well, consider an engine "done for" if it is once thoroughly saturated with some of the fuel compositions.

Economic factors impose the splash system, in its most thoroughly worked out form, as being a good stand-by under all circumstances. Most men understand it best, or, to be frank, pay least attention to it. As an all-around system, it takes care of itself better than any other. The ideal system of fresh oil to all points is perfect, theoretically, but the complication and details, together with thickening of oil in cold weather, make it hard to introduce. The force feed through the crank will become widely used when manufacturers and users know more about it.

Bearings suffer under heavy fuel conditions due to the high pressure of detonation and preignition. Preignition can be controlled by design, as will be noted under cylinders, pistons and rings. Both preignition and detonation are limiting factors of our modern fuels.

It has been our policy to frankly state to our customers just how well we can burn kerosene, its limitations, and wherein it is not as good as gasoline. We have influenced a number of customers not to put on the kerosene equipment, convincing them that the decrease in the cost of the fuel per gallon did not make up for the loss in horsepower and less work done in a day.—H. L. Horning, General Manager, Waukesha Motor Co.

By R. O. Hendrickson

I believe in governing or limiting engine performance by a combination of three factors, as follows:

First—traction.

Second—piston area.

Third—restriction of intake passages.

In regard to splash oiling system vs. pressure, this depends principally on the size and revolutions per minute of the engine, the splash being more suitable for high-speed engines and the pressure absolutely essential for engines where the piston walls are at a greater distance from the crank. The splash system is much simpler.

I believe that where an engine is designed for the use of kerosene fuel, it is quite as satisfactory as gasoline, except for the additional attention required in starting. An internal combustion engine to use kerosene as fuel must be designed throughout with this in mind. An engine of the T or L head type, with large areas in the combustion space, is not very suitable for burning kerosene oil; on the other hand, an engine with a compact combustion space, with proper carbureting attachments and manifolds, is quite satisfactory.—R. O. Hendrickson, Chief Engineer, Wallis Tractor Co.

Duralumin for Metal Airplanes

IN a recent paper presented to the Royal Aeronautical Society of Great Britain, Dr. A. P. Thurston asserted that wood construction of airplanes would give way to metal construction on account of the all-round superiority of certain metals, notably steel and duralumin. As compared with steel, duralumin has many advantages and a few disadvantages. Weighing only one-third as much as steel, it follows that the various members may be, weight for weight, three times thicker than steel members. Hence the difficulty in overcoming local failure due to local flexure is greatly reduced. Nevertheless, the perfection of a design can only be discovered by constructing it in steel, and it is thought that duralumin designs will be improved by adopting the principles which have proved to be the only feasible ones in steel construction.

A prejudice appears to exist in certain quarters against duralumin owing to the fear of corrosion. It should be stated that duralumin, unlike aluminum, is not acted upon by sea water, or affected by atmospheric influences, and experience in connection with airship work shows that duralumin, if properly varnished, is not affected by corrosion under ordinary conditions of service. Nearly every case of corrosion so far experienced in actual practice has been traced back to incorrect heat treatment, or to cold working after heat treatment. The heat treatment of duralumin, instead of being a disadvantage, as is often supposed, is in actual point of fact of the greatest assistance in the practical working of the metal. This heat treatment is carried out by placing the members to be treated in a bath containing a mixture of potassium and sodium nitrates heated to a temperature of 480 deg. C. In practice there is a fairly wide margin of temperature so long as 500 deg. C. is not exceeded, in which case there is danger of the metal being burnt and reduced to aluminum. The parts should be left in the bath long enough to be heated uniformly to the temperature of the path, the actual time allowed being five minutes in the case of small units up to several hours in the case of 3 in. bar. There is no danger in leaving it in the bath too long, providing the actual temperature of 500 deg. is not exceeded. At the end of this time the article is removed from the bath and quenched out in water or non-acid oil. Immediately after heat treatment the metal is found to be in a very soft and plastic condition, and it may be pressed, forged, bent to the smallest radius, or in the case of drawn sections which have warped with the quenching, straightened without any fear of damaging the metal. The metal now commences of itself to harden up, and in about an hour's time has reached about 26 tons tensile strength, with an elongation of about 15 per cent.

This process of hardening continues for a very long period, the strength slightly increasing at the expense of the elongation. Heating duralumin to 300 deg. C. and then quenching out anneals the metal, and it can then be worked in any way desired. In order to give it back its strength it is necessary to heat treat it at 480 deg. C., as explained above. In practice it is usual to anneal any duralumin part if a number of operations have to be performed, and on the other hand to heat treat before final operation if this is not of too prolonged a nature, taking advantage of its abnormal condition immediately after heat treatment. An actual example of the value of this property of duralumin in slowly hardening up after heat treatment occurs when duralumin is used for rivets. If an attempt were made to rivet these up in the ordinary hard condition they would crack badly. By heat treating them, however, and using them immediately after this, a perfect job may be made while they are soft, and within a very short time afterwards they have hardened up to their full strength.

If duralumin in the ordinary hard condition is bent to a small radius there is, as would be expected, a probability of incipient cracks developing on the surface of the metal at the bend. These cracks are the places where the corrosion begins. If the metal was properly heat treated before such bending no injury would be caused to the surface of the metal, and no trouble would be experienced from corrosion. Nearly the whole of the prejudice against the use of duralumin is due to ignorance as to its properties with and without heat treatment. Sections cannot conveniently be drawn thicker than 0.2 in. Above this thickness the sections are extruded. It is advisable to use only solid drawn sections for the constructional purposes and designs should accordingly be modified to meet the limitations in the material.

ACCORDING to a French contemporary, American army motorcycles recently sold at auction in London brought prices above their catalog figures.

THIRTY-ONE of the leading British accident insurance companies have so far issued a list of premiums for flight risk insuranee.

Tractor Design from the Operator's Viewpoint

(*Continued from page* 1311)

The belt pulley should be where a man can either sight over it or set guide marks by stepping off from the belt as it lies on the ground. Also, the belt should clear the operator well so that he will not be caught or struck in tightening up on it. The belt pulley should not be located so that it may catch a man's clothes when not being used in belt work.

Seat springs are apt to break, and if there is any chance of a man dropping in front of a disk or other load, a safety basket should be provided. Considerable improvement might be made in the operating position it is necessary for the operator to assume. A padded or a cushion-back seat is too warm in summer, but saves a man from much jar.

It should be borne in mind that an operator must be at his post all the time the tractor is operating and is unable to run all over the machine to make adjustments and to oil the various parts of the tractor.

Care should be taken not to make individual parts, such as heads of a block motor, too heavy, as very often the operator has no facilities for lifting and has no helper.

These remarks are not intended as a criticism of any one design, nor of designers in general, for the problems involved in getting out a practical machine are not easy. Some of the operator's requirements are much more easily stated than solved, but the success of a tractor and its sale in any given neighborhood depend largely on the operator, and the easier it is made for him to keep going, the better he and the owner are satisfied. Some operators may like to tinker with their machines, but most of us are glad enough to leave them alone, unless some part is in need of attention, and the more easily that thing may be got at, the more likely it is to be fixed before trouble develops. In case of trouble the more accessible rig will get going the soonest; therefore, make your rig accessible.

The Influence of Hitches and Drawbar Location on Tractor Design

(*Continued from page* 1335)

be provided with suitable hitches for tractor operation, and their further use should be provided for.

I do not believe that a successful tractor will ever be a very good cultivator or vice versa, because the operating conditions and requirements, as well as the power demands are too different. Therefore, cultivating implements and their attachments need not be considered in connection with the problem of tractor hitches.

So much for the problem of tractor hitches and drawbar location as related to tractor design; doubtless there will be many to take issue with me on one point of reasoning, and that is the point about which the moments of the various forces act. I have watched dozens of tractors in operation, seen them raise up and even turn over, and the rotation is always about the rear axle and not the point of contact between the drive wheels and the earth.

In proof of the reasoning employed, make of yourself a tractor in the following way, and note the reactions in your own body.

If you stand with the body bent forward at the hips, with a wooden square representing the tractor framework hinged upon a pipe or rod strapped across your back at your hips, and attempt to drag a load hitched onto the lower end of the wooden square, you will observe that the forward end of the horizontal arm of the square presses heavily downward upon your back, and that the harder you pull the more the tendency will be for you to want to straighten up. This corresponds exactly to the forces at work in a tractor, showing that the greater the resistance (or drawbar pull) becomes, the greater the effort becomes to overcome this resistance, and, therefore, the greater the tendency to raise up at the forward end.

As the framework corresponds exactly to the wooden square, and is hinged about the rear axle, it is evident that it cannot rotate about any other point.

Some engineers claim that at the time the tractor overturns it becomes practically a locked or rigid mechanism. If this were a fact the drawbar pull would suddenly have to become an active force in place of a reactive force in order to overturn the tractor, and this, of course, cannot happen.

Waterproof Plywood for Airplanes

(*Continued from page* 1333)

ting veneer has very little effect on the strength of the plywood, but that the plywood made of sawed veneer is inclined to warp less than the plywood that is made of sliced or rudely cut veneer.

An extensive series of tests on glued and riveted joints in plywood was completed. Joints of various types were made, some of which extended through a single ply only, while others extended through the entire plywood thickness. The tests show that the tubular rivet gives the most satisfactory results in riveted joints and that there is very little difference in the strength of joints made of various sizes of rivets, provided that the most effective spacing and margin is used of each size. The scarf joint extending through the entire plywood thickness was recommended in preference to the riveted joint, because it gives a considerably higher efficiency. A scarf having a slope of from one in twenty to one in thirty was found to be very satisfactory.

Tests were made to determine the proper conditioning for plywood which is to be bent in double curvature. A special mold was prepared for this purpose, but the tests made are still too limited in scope to draw any conclusions.

Machines were devised for determining the vibrational strength of plywood and the relative toughness. The tests made to date are still too limited in number to draw conclusions.

Matthews Full Automatic Lighting Plants

(*Continued from page* 1315)

turn through a certain angle and is then held from rotation by an adjustable stop on the dial. If now the current through the relay should be reverse, as in cranking the engine, the relay hand moves slowly in a clockwise direction until it comes up against the contact point. This completes the circuit of the breaker trip coil, which latter neutralizes the hold coil, so that there is no resulting pull, and the breaker armature is released, thereby opening the circuit between the battery and the generator. Thus, after a fixed period of cranking the engine, which is generally about 2 min., if the engine fails to pick up its cycle the generator is automatically cut off from the battery and no undue amount of electric energy will be wasted.

The normal position of the breaker is the closed position with the hold coil energized. If the breaker opens, all control circuits are dead, and all coils and relays in the released position, and the lights are cut off.

European Restrictions

INSTEAD of France and Great Britain ameliorating on the question of import restrictions and the import duties to follow the removal of restrictions, the present sentiment in both countries to protect their respective industries is increasing. The reason lies in the fact that for many years America used its high tariff wall of 45 per cent against European manufacturers, and now these European makers do not especially cherish the suggestion from America that import restrictions should be removed and low import duties levied.

The probability of the removal of the British import restrictions September 1 is not so bright as it was a month ago. The 9 months of import restrictions do not seem sufficient for the British manufacturer, who has been somewhat slow in rearranging his business after the war, although perhaps not open to criticism, as the work of re-arrangement has increased as months have passed.

France has frankly stated that her manufacturers are capable of caring for the needs of the civil population in that the interests of the country must stand ahead of the interests of any particular industry. The civilian population may require more vehicles to-day than the manufacturers can furnish, but if throwing down the bars to America, because she has the vehicles at hand, would bankrupt the French industry, then the French Government is entirely rational in its view.

America is to-day paying part of the price of the high tariff duty that has always been against the European manufacturer. The 10 years when European makers had to meet the 45 per cent duty are not forgotten. As France puts it, after American makers have built up business behind a 45 per cent tariff protective wall, it is hardly good grace to tell France she should not have a high tariff protective wall to rebuild her industries after the war. If the protective wall was good for America in the early days of the industry, and up to the present, then it should be good for France to-day. Perhaps we were not so much concerned about giving our civilians cheap European cars 10 or 12 years ago as we are giving French civilians cheap American cars to-day.

The best thing for the automobile industry in America is to have a healthy automobile industry in England, France, Italy and Belgium. It would be scarcely short of a calamity to have the French automobile industry bankrupt. The same applies to the British industry. Both of these countries have played a large part in the development of the industry. The British maker played it without a protective tariff. The French maker did it with a relatively low tariff. He has been the developer. We did it with a high tariff. Because of this we should attentively listen to the requests of France and England for the protection of their industries for a given period.

As Japanese Do It

SOME American business men have expressed astonishment at the ability of the Japanese to gain and hold export trade. While the Americans knew there must be a reason, a good many of them apparently were not able to discover that reason. There are many reasons for the Japanese success, and one of them is set forth in the recent summary of foreign trade printed by the Guaranty Trust Company of New York. In the Japan report this review says:

> The Japanese merchants do not intend that their new found trade shall be lost, and with the assistance of the Government are making strenuous efforts to retain their place, and to remove any stigma of inferiority which, rightly or wrongly, may be placed upon their goods by foreign purchasers. In Australia, for instance, it is reported that the Japanese consul-general reports all complaints received direct to his Government, which in turn traces the defective product to the factory in which it was produced. In some cases, the consul actually guarantees on behalf of his Government the quality of the merchandise.

This would appear to be a very good foundation of a successful trade. Some reports have it that all American firms do not place quality first.

Tractor Rating

THOSE favoring a revision of the existing tractor rating formula for belt and drawbar should not overlook the reason for a revision which seems to lie in the present chaos in the minds of the farmer and the dealer, brought about by over-rating of tractors and misleading conclusions as the result of manufacturers' ratings. As an outcome of this, one state has legislated that its university would conduct practical tests and give ratings before tractors can be sold within its confines. Other states are taking different action.

If it is these conditions which have brought about the present agitation for a revision of the rating formula, the new rating should at least correct present abuses and clarify the situation for the farmer and the dealer. The new rating will unquestionably be used as a merchandising argument. It will carry a stamp of official recognition and, as such, it must represent the power capacity of the tractor and should take into recognition superiority of design and construction.

The old rating, known as the S. A. E. rating, which rates a tractor at 80 per cent of its drawbar performance on a 2-hour test, and 80 per cent of its belt performance on a 2-hour test, should be satisfactory. The trouble is that it has not been lived up to. There is no camouflage in it. The tractor must perform and, following this formula, there is little danger of over-rating.

A proposed formula bases the belt rating on the piston displacement of the tractor in connection with the r.p.m. and a constant 13,000. This has all of the earmarks of rating a tractor on a dimension basis. Piston displacement is merely a product of the cylinder dimensions. It has been known for years that the product of an engine in horsepower is not merely dependent upon cylinder dimensions.

The development of internal combustion engines in the last 8 years has been along the line of higher efficiency as a means of increasing power, rather than increasing dimensions and hoping for an increase in power. Many engines have had their power vary without adding to the cylinder dimensions. In an internal combustion engine, power is the commodity to be purchased and not cylinder dimensions or weight. The formula to be used as a criterion of power in merchandising a tractor should then primarily have regard for the power output rather than merely the displacement of the engine. The proposed rating gives the impression of rating on a tonnage basis rather than on a performance basis.

The possibilities for sales reception with such a rating seem dangerously broad. With three engines of the same dimensions, there will be a different performance in each. Good design, careful workmanship, accurate inspection, and good materials, will give power in one engine. In another, the lack of these will result in loss of power. All three, however, will be able to be presented to the farmer as equally efficient engines. The ratings will be the same. Here lies the merchandising danger. On the face of it, such a formula makes an imperfect rating the dominant official factor in a sale. Such a rating begins in a fallacy and ends in confusion. The fallacy is that while purporting to give a statement regarding horsepower, you do not in reality give the horsepower. The confusion is that the consumer has no assurance from the dimension argument that he is getting the horsepower he thinks he is.

With this being the case, how can such a proposed rating correct the existing evil of uncertainty in the minds of the consumer and the merchandiser? It seems to be but another example of shifting the issue. There seems a special danger at this time of establishing such a rating in that we are unquestionably on the verge of developments in internal combustion engines that will give the greater return on the fuel expenditure and a mere dimension rating would not take anything like due consideration of such. It would seem to be merely befogging the tractor confusion to change the present rating and adopt the proposed one.

There is only one way to measure horsepower, which is the commodity for sale, and that is by an engine test, as proposed in the existing S. A. E. rating. It is difficult to see any legitimate reason why any manufacturer should object to a rating based on the actual ability of the vehicle to perform. With horsepower the commodity the farmer wants, let us get a rating that will give him a criterion of horsepower.

Emigration and Machinery

MACHINERY, which will take the place of human hands in performing arduous work, must be developed to a state far beyond what it has now reached. The demand for this machinery is becoming greater every day. The increasing rate of emigration taking away from these shores thousands of the foreign-born who were willing to man the pick and shovel is going to make it necessary to use machines for operations far smaller than they would have been used upon a year ago.

The loading time of the motor truck is so important to its economical operation that contractors and fleet owners are watching this development very closely. When a machine cuts loading time from 20 minutes to 2 minutes, it may be instrumental in saving thousands of dollars on one job. In fact in the excavation in Detroit for the U. S. Base Hospital No. 36, machine loading saved $15,000 on the excavating work, and this was during wet weather. The saving of labor is even more significant.

Court Limits Picketing of Overland Plant

Defines It as "Act of Aggression" in Important Opinion Granting Injunction—Plant Opens Again

TOLEDO, June 9—Aided by an important court decision against picketing the Willys-Overland Co. will attempt to operate again this week. Vice-president and general manager Clarence A. Earl said to-day the gates would open to workers Thursday and if unable to do so at that time, they would open Monday at the latest.

Federal Judge Killits has limited the number of pickets to be on duty when the plant opens to 150, not more than 50 to be on duty at one time and a maximum of six to be stationed at a gate. The judge ordered that in event of disorder, attributable to pickets, the privilege of picketing be abolished. Picketing is to be permitted from 6 a.m. to 6 p. m., and a deputy U. S. Marshal is to be on duty at each gate to superintend. All gates used by workers, excepting 12, are ordered sealed.

The pickets are required to wear large badges. Only citizens are to be used as pickets. They are not to be stationed within six feet of the gate. The injunction becomes effective at 2 p. m. Tuesday and runs until 10 a. m. June 19.

The opinion is a sweeping one and sets a precedent which other courts may follow in similar strike cases. It brands picketing as an act of aggression and takes a definite stand against it.

The Electric Auto-Lite Corp., Toledo, opened Wednesday, operating under an injunction issued by the United States Court last Friday, which limits picketing.

DUNLOP OFFICIALS HERE

NEW YORK, June 10—George du Cros, J. V. Worthington and F. C. Baisley, directors and executives of the Dunlop Rubber Co., England, are in this city. They are here to study conditions in the automotive and tire industries.

Various rumors now circulating in regard to their plans are not to be taken too seriously, they state. The results of their investigations will be made known in due course in AUTOMOTIVE INDUSTRIES.

MAXWELL-CHALMERS MERGED

NEW YORK, June 12—The completion of the consolidation of the Maxwell-Chalmers plants awaits the action of the directors of these two companies. Meanwhile the general plan of the merger has become known. The new company will issue 400,000 shares of stock of no par value, which will be distributed as follows: Maxwell first preferred, 120 per cent; Maxwell second preferred, 60 per cent; Maxwell common, 15 per cent; Chalmers preferred, 90 per cent; Chalmers common, 15 per cent.

An issue of $10,000,000 notes convertible into common stock, will provide for the expansion of the new company. Other details are the subject of negotiations. The Maxwell-Chalmers Corp. has started construction on a $10,000,000 manufacturing plant here. The plant, when in operation, will employ between 15,000 and 20,000 men and will have a capacity of approximately 500 cars a day. The capacity of the present plant is 100 cars.

A.A.A. Would Modify Federal Road Act

ATLANTIC CITY, June 9—The American Automobile Association, in annual session here to-day, indorsed the Federal Aid Road Act, now pending in Congress, with the suggestion that the act be amended to restrict the aid given from Federal funds to roads that are part of a well defined state system. It was also suggested that the Secretary of Agriculture be given authority to increase the aid given to 75 per cent in certain cases instead of the regular 50-50 plan.

Progress was noted in the plans for unifying taxation laws, anti-thievery measures, effective hand signaling and road beautification.

Mrs. Robert Lee Morrell, a New York attorney, was elected a vice-president. She is the first woman to hold office in the association. David Jameson of Pennsylvania, was re-elected president. Other officers are: Vice-presidents, Ralph W. Smith, Colorado; P. J. Walker, California; H. J. Clark, Minnesota; Clifford Ireland, Illinois; Dr. John H. Quayle, Ohio, and Dr. R. R. Elmore, Kentucky. H. A. Bonnell of New Jersey will begin his twelfth year as treasurer. John N. Brooks of Connecticut is again secretary. A. G. Batchelder holds over as executive chairman.

WILLS-LEE CANADIAN PLANT

DETROIT, June 12—John R. Lee today said that he and Mr. Wills would build a large automobile plant in Sarnia, Ont. This plant will manufacture their new car and will employ about 2000 men. Sarnia is directly across the river from Port Huron. The Canadian plant thus will be directly opposite the American plant. The Canadian plant will not be started until the American plant is completed.

Detroit Labor Back in Production

Factories Running in Spite of Labor Difficulties—Car Industry Not Affected

DETROIT, June 10.—In spite of a street car strike with all cars idle, the labor situation is improving. The 1500 Studebaker strikers at plant No. 3 are back to work. The issue here was not a matter of wages or hours but one of conditions. The strikers charged discrimination and asked for the reinstatement of certain discharged men. The men were not reinstated.

The strike at the Timken-Detroit Axle Co. is entering its fourth week without sign of adjustment. The men are holding out for increased wages, readjustment of the piece scale system and shorter hours. Production at the plant reached a low ebb but the company is now getting back into operation on a fair scale. This strike has been peaceful. The police are providing the company with plenty of protection.

Ford Workers Help Wadsworth

The Wadsworth Mfg. Co. is still running after six weeks of strike. New men have been taken into the organization to replace those who quit their jobs. During the first three weeks, production of Ford sedan bodies was cut to a minimum but during the last three weeks operation has been resumed in many departments and production is increasing. The Ford Motor Co. sent hundreds of workers into this plant when the strike was called and saved the day for the Wadsworth Co.

The Foundry workers are very restless and a number of strikes in local foundries is hampering parts production. The Detroit Forge Co. workers are on strike. They demand a wage increase and an 8-hr. day.

ORDNANCE FOR S. A. E.

NEW YORK, June 12—Word has been received from the War Department that 30 carloads of automotive war apparatus have been shipped to Ottawa Beach, Mich., for the summer meeting of the S. A. E. on June 23-28. The material sent includes tanks with and without guns, 8 trucks fitted for various forms of shop work, such as air compressors, power saw, drill press, etc. There are also various sized tractors, up to 10 tons and some French guns. This equipment will be in place for the meeting.

The number of reservations to-day was 608.

Automotive Industries

Slight Prospect of Trade with Europe is Hanch's Report

Secretary of N.A.C.C., After 4 Months Abroad, Has a Gloomy Export View

French Remind Him of Our High Tariff on Their Cars Before War and Now

NEW YORK, June 9—At present there is no indication what will be the attitude of the government of Great Britain toward removing present restrictions on the importation of automobiles after Sept. 1, 1919, is the opinion of C. C. Hanch, secretary of the National Automobile Chamber of Commerce, after his 4-months' investigation of conditions in Great Britain, France and Italy, and after his attending a meeting of the automobile interests of the Allies in Paris, March 5 and 6, 1919. Mr. Hanch's report was read to those present at the N. A. C. C. meeting here.

The automotive manufacturers of Great Britain, France and Italy are insistent upon receiving absolute protection against the United States for a considerable period, say 2 years, and substantial protection thereafter. They naturally have certain influences with their respective governments and unless public opinion intervenes, it is likely that import restrictions will be continued for a considerable period.

According to Mr. Hanch there is a serious shortage of automotive equipment in these European countries and a great demand for motor apparatus, so that the existing restrictions are working hardship on the population.

France takes issue with Mr. Hanch and asserts that the French manufacturers are well able to furnish all the automotive equipment necessary for the French population, and does not take kindly to the requests that French restrictions of importations be removed. They unqualifiedly declare that they cannot subscribe to any such plan for America selling automobiles in France as suggested, and further draw attention to the fact that for practically 10 years America had a 45 per cent ad valorem duty on French cars, while at the same time France was exacting an import duty of from 8 to 10 per cent on American machines.

In the view of France, the treatment by America was hard and unjust and, to-day, it is but natural that the French manufacturers should urge the French government to apply to each of the Allies what those Allies think proper to apply to France. In a word, this means that if America applies a 45 per cent ad valorem duty on French products, then the French government should apply a similar duty on American products.

The whole question was discussed at the conference in Paris, March 5, by representatives of the automobile industry from England, France, Belgium, Italy and the United States, reports of which have already been published in AUTOMOTIVE INDUSTRIES.

Mr. Hanch, in his report to the N. A. C. C., says that he pointed out the injustice of import restrictions in a letter to the secretary of the French organization known as the Chamber Syndicate des Constructeurs d'Automobile. Fully 20 per cent of Mr. Hanch's report is taken up with his letter and the French reply and, from the latter, it is quite evident that the French do not coincide with the views expressed by Mr. Hanch as representing the N. A. C. C.

There was another conference held after March 5 in which French manufacturers expressed a slight change in opinion and indicated that they would not advocate a continuance of the embargoes after July, 1919. It might be inserted here that since Mr. Hanch left Paris the French automobile manufacturers have recommended that, after the signing of Peace, France will adopt a duty of 45 per cent on American automobiles until January, 1920, and after that date the duty will be 15 per cent.

Favors Removal of Restrictions

Mr. Hanch, in his letter to the Chambre Syndicale des Constructeurs d'Automobile, talked in favor of France removing restrictions because of the general shortage of automobiles in France, the inability of the French manufacturer to meet the demand and the strong demand on the part of the French industry for automobiles. He summed his conclusions under the following heads:

1—There is a material shortage of transportation traction equipment for civilian use in all European allied countries.

2—The European manufacturer cannot supply the required amount of automotive equipment needed by the civilian population as soon as it should be provided to permit the economical welfare of European allied nations.

3—The manufacturers of the United States are in position to furnish a part of the automotive equipment needed by the civilian population of the European allied countries.

4—The needs of the civilian population of European allied countries will absorb the production of European manufacturers as well as equipment which can be furnished by the U. S. A.

5—Further delay in granting import licenses, or in removing embargoes, can only result in serious injustice to the European allied countries by preventing such population from securing its requirements as soon as needed and also by encouraging extortionate prices for second hand and other equipment.

6—The earlier the trade relations between all the allied and friendly nations are established the sooner will be the return to normal and economic conditions in all the countries.

7—The early removal of embargo and the granting of import and export licenses is in the best interests of all nations concerned.

That the French Chambre Syndicale des Constructeurs d'Automobile quite seriously objected to being told by Mr. Hanch what was best for the French civilian population and what were the requirements, is indicated by the letter written by H. Cezanne, general secretary of the Chambre. The latter was couched in the typical French language which has suffered considerably in translation, but still indicates how very much France resented dictation from America as to what she should do for her own people.

Undoubtedly France thought of the days when America put a 45 per cent duty against her products, and has retained it practically up to the present time, and wondered why America, who

(*Continued on page* 1371)

Rubber Imports Slow Up in May

16,348 Tons Come in, Compared With 27,948 Last Month

NEW YORK, June 11—Imports of crude rubber into the United States in May were only 60 tons ahead of the amount imported in the same month last year, a drop of 11,600 tons from last month's figures.

Comparative figures for the past four years, as compiled by the Rubber Association of America, follows:

	1919 Tons	1918 Tons	1917 Tons	1916 Tons
January	7,235	16,084	12,788	9,162
February	14,079	13,108	10,162	1,597
March	28,223	17,161	18,624	10,070
April	27,948	13,425	13,000	10,014
May	16,348	16,288	18,411	11,189

War Work Considered in Show Allotments

N.A.C.C. Permits Manufacturers to Enter Production for 1919, 1918 or 1917

NEW YORK, June 11—War work was recognized in the drawing of spaces for the coming national automobile shows by the National Automobile Chamber of Commerce at the meeting held here last week. It was decided that the spaces should be allotted on the factory production for any of the three last fiscal years ending June 30. In other words, the manufacturer may elect whether he will enter his production for the year ending June 30, 1919, 1918 or 1917.

The shows, as stated last week, will be held in New York at the Grand Central Palace, Jan. 3 to 10, and in the Coliseum in Chicago on Jan. 24 to 31. Coincident truck shows will be held in both cities. The site of the New York truck show probably will be in the Twenty-Second Engineers Armory at 168th Street and Broadway. The Chicago truck show will be held in the Drexel Pavilion in the Stock Yards district.

Two special sessions of future possibilities were held in connection with the meeting of the N. A. C. C. One was the meeting with the representatives of the oil trade on Thursday night. At this meeting it was learned that the automotive manufacturers and the oil-men have been working without the mutual understanding that would be exceedingly helpful to both. Especially was the forecast for truck production in 1919 as presented there a surprise to the oil-men.

Export Managers Hear Hanch

The second special session of interest was that of the export managers. They heard a report from C. C. Hanch, who has been studying conditions in Europe for six months past. In addition to his formal report, Mr. Hanch was kept on the floor for two hours answering questions. Preparations were made for special investigations of three developments from this discussion, which probably will have a direct bearing on the future trade. It was voted to broaden the foreign trade department of the Chamber. The showing was that the export now is $125,000,000 of the total $1,300,000,000 automotive business.

A constitutional movement to increase the number of directors of the Chamber from 15 to 18 members was originated.

The following directors were re-elected: John N. Willys (Overland), H. H. Rice (Chevrolet), Roy D. Chapin (Hudson), C. C. Hanch (Studebaker), and J. Walter Drake (Hupmobile). At the next meeting a constitutional amendment to increase the directorate from 15 to 18 members will be offered to provide for further representatives of the truck industry. At present there are five members of the truck industry on the board of directors.

THE FUEL CONFERENCE

NEW YORK CITY, June 10—A so-called cabinet for the consideration of fuel problems was a result of the meeting Thursday night of representatives of the automobile industry and the petroleum industry to consider what should be done for the general good on the fuel situation. This cabinet of ten is expected to outline the fuel problem and to guide the united efforts of the fuel people and the apparatus manufacturers in the right direction. This objective is to give a better fuel, and improvement, perhaps, in apparatus to handle the fuel, as engines and vaporizers.

There was no dissenting view expressed by either side on the subject. Both are united in their purpose to work together to this end. With many of the oil-men, there seems to be no fuel problem and some of them are apparently ignorant of the difficulties of properly handling fuels on the market.

From an oil-man's point of view the increased output of fuel is merely one of a broader use of the cracking process, which is gaining all the time, as well as the sinking of more wells. It seems impossible to produce a better fuel than we have to-day and produce it in the same quantities from a given amount of crude. If we want to increase the fuel, we will have to lower the standard. If we want to increase the quality it will be necessary to lower the volume.

At present the fuel interests are well over-stocked with fuel oil and some of the refineries are closed down temporarily on this account. The dropping off in war demand has been the cause of this.

PRICES OF ARMY TRUCKS

WASHINGTON, June 9—The Sales Division of the War Department, following its recent conference with the trade press and the industry with regard to the sale of surplus motor vehicles, is now fixing the prices and will soon catalog them and send the catalog to the various district offices of the War Department.

The trucks will be sold either by auction for cash, or to the highest bidder on sealed proposals on due public notice, or at the current market price or by negotiations under competitive conditions, providing the price obtained is not less than that fixed by appraisal or is the highest of not less than three independent competitive bids. The supply and condition will decide the methods chosen.

WINTHER EXPANSION PLANS

KENOSHA, WIS., June 9—The Winther Motor Truck Co., at a special meeting of the board of directors, June 11, will vote on the plan to issue $1,000,000 of common stock, most of which will be taken by present holders. The proceeds will be used to increase the facilities and otherwise finance expansion. The present plant was erected a few months ago at a cost of $150,000 and a second unit of equal size is proposed.

Paris Show Will Be October 9-19

Space Requirements Will Place Decided Handicap on American Exhibitors

PARIS, May 22—Oct. 9 to 19 inclusive have been fixed as the dates for the 15th French automobile show, which will be held in the Grand Palais in Paris after a lapse of 4 years. This is the first automobile show to be held in Europe since the war and will inaugurate the series that will include London and Brussels.

American exhibitors are at a disadvantage compared with European competitors. One of the rules states that allied manufacturers can be admitted on the same footing as French makers, providing they have taken part in at least three previous Paris shows, and also providing that the import duties in their own country prior to 1914 were not higher than 15 per cent ad valorem. As the United States is the only country in the world having a duty higher than 15 per cent, it is evident that this rule has been adopted entirely with the object of handicapping American exhibitors.

The regulations state that foreign exhibitors who do not comply with these requirements will be given special spots decided on by the committee. This practically means that they will have to take whatever spot may be available after everybody else has made a selection.

When the war broke out in 1914, numerous firms had made a request for space and had, in many instances, deposited the entry fees for the 1914 show. These firms will receive preferential treatment when space is allotted.

No enemy firm can exhibit at the Paris show.

Stands will be uniformly decorated and will be delivered completely equipped with signs, carpets, etc., ready for receiving the actual exhibits. As in previous years, a refund will be made to all exhibitors after expenses have been paid.

The Grand Palais, which is the biggest hall under one roof in Europe, if not in the world, has been occupied by the military during the war. It has just been released and is being repaired and equipped with the show in view. There is no doubt that every inch of space will be occupied. The president of the Show Committee is Baron Petiet, president of the French Society of Automobile Manufacturers. Henri Cézanne is the general manager of the show.

American manufacturers desiring space are recommended to apply without delay to 51 rue Pergolèse, Paris.

DETROITER CREDITORS TO MEET

DETROIT, June 9—Creditors of the Detroiter Motor Car Co. will hold a final meeting at 117 Fort Street, west, on June 25 to pass on the trustees' report showing property for distribution, etc., and offer for sale the balance of unpaid accounts receivable.

Italian Factories on 8-Hour Schedule

Experiment of No Lunch Hour Fails—Strike of Foremen Serious

TURIN, ITALY, May 20—All Italian automobile factories have been on an 8-hr. day basis since March. The attempt has been made to run a single shift of 8 hours without stop for meals. This is still being done at the Fiat factory, but it is recognized that the experiment is a failure. The seventh and eighth hours are not productive, and after working for that length of time it is impossible for the men to do overtime.

In consequence Fiat will shortly change to four hours in the morning, two hours for the mid-day meal, and four hours in the afternoon.

The Lancia factory also adopted the 8-hr. day without a break, but has changed over to 8 to 12 and 2 to 6. The reduction from 10 to 8 working hours a day has been made without any diminution in the weekly wage. On piece work an increase of 25 per cent has been granted.

A strike which affected all Italian automobile factories has just been brought to a close after one month's duration. The foremen and heads of departments, being dissatisfied with working conditions, left the shops. An attempt was made to run without these men, but it was not successful, and practically all the shops had to close.

Although an agreement was arrived at after 31 days, it is reported that the interruption has thrown the factories back at least two months.

IN FRENCH TIRE FACTORIES

PARIS, May 20—The 8-hr. day has been permanently adopted in the French factory of the Goodrich Tire and Rubber Co. at Colombes, near Paris. Owing to the shortage of coal, the work hours had been reduced on many occasions and, when the Government law was proposed, it was decided to make the 8-hr. day a regular feature.

Arthur Lumsden, the director of the French Goodrich company, has adopted the plan inaugurated a few months ago by the neighboring Gnome & Rhone Co. of having a break of only half an hour in the middle of the day for a meal. To do this it has been necessary to erect dining rooms, as the French laws forbids eating in a building where work is carried on.

While the 8-hr. day is well received by French workmen, the objection is being raised by their wives that the men have too much time on their hands and consequently spend too much money for drink.

There is no doubt that the drop in France from 60 to 48 hours a week will raise social problems in which employers of labor must take an interest. When working 60 hours a week, a man's time was fully occupied in working, sleeping and eating. The French working man had few hobbies. Now that spare time has been thrown on his hands, there is danger of his misusing it, if not educated to better ways.

ITALIAN EXPORTS

TURIN, ITALY, May 10—Italy exported 1867 trucks and 1071 passenger cars, having a nominal value of $9,068,500, during the year 1918.

This is a considerable drop on the two preceding years, for in 1917 the number was 8734 with a value of $22,995,761, and in 1916 it was 6463 trucks and passenger cars valued at $16,806,450.

The decrease is due to the cancellation of army contracts. In 1916 and 1917 Fiat alone was building from 60 to 100 trucks a day, 50 per cent of them going abroad. This was cut down by about three-quarters when the armistice was announced.

The number and value of exported passenger cars has increased, being 1071 in 1918, compared with 702 in 1917 and 824 during 1916. Although only two out of the twelve months of 1918 were under partial peace conditions, the returns indicate that Italy's greatest activity will be in passenger cars rather than in trucks.

Automobile imports were lower during 1918, only 50 trucks and 30 passenger cars, valued at $161,820, being brought into Italy.

PROGRAM FOR MECHANICAL ENGINEERS

DETROIT, June 10—The spring meeting of the American Society of Mechanical Engineers, to be held here June 16-19, will have at least 22 papers, according to the present schedule. The first session will be largely taken up by the regular society business.

Of particular interest to the automotive industry is the gas power session, which will consider the internal combustion field, including the Deisel and other types of oil engines, and the kerosene engine. Carburetion will also be taken up during this session. Another session will be on fuel economy, which includes papers on pulverized coal and fuel oil.

Industrial relations will be treated by at least three speakers and probably others will be announced. This session will be on Tuesday afternoon.

The production of Liberty engine parts at the Ford plant will be treated by W. F. Verner on Wednesday morning.

A paper, "Crude-Oil Motors vs. Steam Engines in Marine Practice," by J. W. Morton, one by D. L. Arnold, entitled "A Suggested Formula for Rating Kerosene Engines," and "Standards of Carbureter Performance," by O. C. Berry will be presented.

Airplane subjects will be given attention on Thursday, when there will be a paper entitled "Elements of a General Theory on Wing Design," by Walter C. Durfee, also "Air Fans for Driving Electric Generators on Airplanes," by Captain G. Francis Gray, Lieut. John W. Reed and P. N. Elderkin.

Used Cars at Premium in Italy

Manufacturers There Putting Export Trade First, While Imports are Barred

TURIN, ITALY, May 20—There is a very strong demand throughout Italy for both trucks and touring cars. The factories are unable to meet local requirements, with the result that used cars are bringing fancy prices. The army has not offered any of its cars for sale, thus tending to maintain the artificial price of used cars.

The home manufacturers have nothing to fear, for automobile imports are prohibited. Indeed, in many cases Italian manufacturers are more interested in exporting, in an effort to establish foreign markets, than in meeting the requirements of their clients at home.

The result of this is that there is sharp competition for any used cars which may be put on the market, and in most cases used cars are sold considerably in excess of the prices asked by the factories for new models. As an example, a used Fiat 3½-ton truck can be sold for more than the Fiat Co. price for a new truck. Four-year-old Lancia cars are bringing as high as $12,000 at nominal rate of exchange.

It is certain that the army is making a mistake in not placing its surplus trucks and cars on the market while the demand is great and the supply small. Within six months the factories will be producing in large quantities and the bottom will drop out of the second-hand car market.

Lancia has decided to continue his 4-cylinder 30-hp. model produced before the war. The only material change is the adoption of the detachable cylinder head. This change has become general in Italy, for it has been taken up by Fiat, the biggest producer, and also by Nazzaro, who is now preparing to build a high-class four with detachable head and valves in the head.

Nazzaro has abandoned his original factory at Turin and is taking over the new works at Florence.

ARMSTRONG-SIDDELEY NEW CAR

COVENTRY, ENGLAND, May 27—The Siddeley-Deasy Motor Car Co., Ltd., will soon be known as the Armstrong-Siddeley Co., Ltd., and the car to be manufactured, as the Armstrong-Siddeley.

The new Armstrong-Siddeley car will use a six-cylinder engine, with overhead valves, in which aluminum construction will figure prominently. The cylinders will be 3½ x 5¼. Features to be incorporated are spiral bevel axle drive, cantilever springs, disk wheels and electric starting and lighting. Deliveries will begin in August. The price will be $3,300. The entire manufacturing efforts of the company will be concentrated on one model.

English Manufacturer Slow in Production

Labor Troubles Blamed for Inactivity — Importers Want Duty Removed

LONDON, ENGLAND, May 28—One cannot help but be amazed at the slowness with which the British manufacturer is returning to normal business. Practically 50 per cent of the car makers have not yet delivered a single car to the public, and there are scarcely more than four firms that are producing 50 per cent of their pre-war output. The invariable excuse for the delay is labor troubles.

British importers of American cars take the view that the only hope for the British automobile industry lies in the removal of the present prohibition. If the restrictions on imports were removed, the British makers would then have to make a determined effort for the business and would put up what is described as a real sporting fight.

By Sept. 1, British manufacturers will have had 9 months in which to clean up after the war, and prepare to meet any competition, but the sentiment is growing that restriction of import may be continued after this date, and some take the view that there may be an increase in restrictions. At present it is almost impossible to get any united thought on the subject. The view is held that it will be necessary to have another general election in the near future at which time the whole subject will come up for review as a national issue.

There is beginning to be heard in England an outcry against the introduction of a tariff under the government administration without having the direct sanction of it from the voters.

LONDON, ENGLAND, May 28—The difficulty of British manufacturers to get under way with production is accentuated by the uncertainty with regard to the price of coal. This is having a serious effect upon the industry. It is difficult to secure close prices for material. While there is a great deal of restless talk among labor, manufacturers generally agree that these will smooth out as time passes.

Some factories under the 47-hour a week schedule which began Jan. 1 are turning out as much as they used to in the 53-hour week, with the same number of workers. There are others who are having considerable difficulty under the shorter week, and at certain establishments workers have refused to work on a piece basis and are working slower on the hour basis. Recently the wood working trade union forbade any piece work system in the future for its members. There are some factories in which this order is not being observed.

TRUCK DEMAND HEAVY

LONDON, ENGLAND, May 28—The demand for motor trucks is so far in excess of the supply that deliveries in 8 weeks is the best that can be had for any standard British make of trucks.

This delay in delivery is all the more important because the government is not handling the disposal of war trucks as was hoped it would. Officials in charge of selling war trucks seemed more desirous of getting high prices for individual trucks than speeding sales and getting rid of the war supply. Although there are 20,000 trucks supposed to be ready for sale, many of them new, only 500 or 600 per month are being released for public sale to consumers. Some of the dealers are endeavoring to buy from the government trucks of the make they handle, but it has not been possible to do so.

In the meantime there are many automobile parks where thousands of trucks can be seen half buried in mud without means of protection, and at the same time prospective owners cannot make purchases.

This needless delay is largely due to the fact that the government is tied up with peace negotiations, and those in charge do not seem to have the business vision that the situation calls for.

OPPOSES EUROPEAN BRANCHES

NEW YORK, June 12—C. C. Hanch, who inspected the automobile industries in Great Britain, France and Italy as a representative of the N. A. C. C., is not much in favor of American automotive manufacturers establishing branches in Europe at present.

They would have no advantage because import restrictions and high custom duties apply to parts of vehicles, as well as to completed vehicles.

It would be some time before American manufacturers could install the necessary manufacturing equipment in Europe to go on a production basis, and by the time such factories were established, import restrictions would be removed and custom duties modified, so that exporting of the completed vehicle from America would be more desirable than the assembly of it in Europe. At present labor conditions in Europe are also unsatisfactory.

War Department Surplus Vehicles Transferred

WASHINGTON, June 12—The Director of Sales of the War Department this morning approved the transfer of the entire surplus of serviceable motor vehicles held by that Department to other Government departments, a total of 39,100 vehicles. This action leaves fewer than 1000 vehicles to be sold at public auctions. These are unserviceable because of design or for other reason, and will be available only for parts or junk.

FORD STEEL ORDER

NEW YORK, June 12—An order for 150,000 tons of steel, with a possibility of an increase of 200,000 tons, by the Ford Motor Co. is announced by the U. S. Steel Corp.

"Liberty Fuel" Soon to Have Real Test

One of Originators of Much Disputed Compound Says It Will Be Put on Market

CHICAGO, June 7—Liberty fuel, the special motor and airplane product developed by the Government for its war trucks and planes, and regarding which conflicting reports came from Washington early in the winter, is to be put on the market in large quantities within a short time, according to former Major Zimmerman, who was instrumental in its development. Zimmerman made this statement in enlarging upon his theory that one of the greatest developments of the future in the automotive field would be the chemical treatment of fuels to increase their volatility and reduce the heat losses through cooling and exhaust.

The announcement of the marketing of Liberty fuel came in a discussion of a paper on "The Design of Intake Manifolds for the Present Heavy Fuels" by F. C. Mock, engineer of the Stromberg Motor Devices Co., presented at the June meeting of the Midwest Section, Society of Automotive Engineers, last night. In answer to a question as to conflicting reports of the value of Liberty fuel, Zimmerman said that road tests covering thousands of miles were made and that no undesirable features were shown. The varied reports, he said, were directly due to war conditions in Washington.

In his paper on intake manifold design Mr. Mock discussed the necessities for proper carburetion, particularly the shape and heating of the manifold. He definitely advised against any attempt to heat the fuel in the float bowl of the carbureter, because in many sections of the country there are fuels which contain a percentage of very volatile elements, casing head gasoline being a sample. He gave it as his belief and hope that the time is coming when the service departments of each responsible motor car and motor truck manufacturer will develop fittings and connections of this nature to replace the equipment of cars now in service. After the patterns and tools are once made the cost of production is low, and the application could probably be made in half a day, so that the complete installation should not cost over $10 or $15.

Mr. Mock's paper will be printed in a future issue of Automotive Industries.

COMPLAINT AGAINST PREST-O-LITE

WASHINGTON, June 10—A complaint alleging that exclusive contracts made by the Prest-O-Lite Co., Indianapolis, are in violation of the Clayton anti-trust act has been issued by the Federal Trade Commission. Deposits required for the use of steel gas containers are the basis of the complaint. The company is cited to appear July 24.

Ships, Investments, Parcel Post at Pan-American Conference

Latin American Countries Anxious for Better Shipping Facilities with U. S.—Protection of Trademarks Necessary—Press Relations

WASHINGTON, June 9—The immediate establishment of ample freight, mail, and passenger steamship facilities between North and South America, the necessity of investing American capital in South America, the elimination of unnecessary restrictions on parcel post shipments and the need for a well-defined program for the protection of patents, trademarks and copyrights in Latin America were the principal developments of the Pan American Convention which closed here last Friday following a 5-day meeting attended by more than 700 delegates.

The Latin American representatives were particularly pleased with the announcement by Edward N. Hurley of the U. S. Shipping Board, which told of the proposed establishment of great fleets of vessels between the U. S. and the southern continent. They stated that this is the most important requirement of the Latin American countries, and that the development of better shipping and mail carrying facilities will insure an expansion of the trade between the two continents.

Parcel Post

The need of new treaties between the U. S. and the Latin American countries providing for removal of restrictions and regulations on parcel post was mentioned by several speakers, including Frutos Plaza of Montgomery Ward & Co., who praised the increasing efficiency of the parcel post between the U. S. and Latin America, but decried the regulations existing in Brazil and Argentine, which prescribed the use of customs brokers whose fees make the employment of the parcel post practically impossible.

Mr. Plaza told also that the delivery by parcel post in South America had improved remarkably in the past few years, and cited as an instance a shipment made by his company of 300 parcels to Bolivia, each under 11 lb. in weight to conform to the legal limits, and each of which arrived safely and promptly to its destination in the interior of the country.

The necessity for protecting trademarks was illustrated by the examples of the Hupmobile, Renault, Pierce-Arrow, Fordson, and other well-known American trademarks, which have been registered or applied for by natives or European concerns, and which are consequently lost to the American owners. The countries of Latin America, it was said, have furnished a particularly profitable field for the registration of trademarks by others than their originators for speculative purposes, and nearly every issue of the official bulletins of these countries contains applications for trademark registration that are fraudulent or at least unauthorized.

Manufacturers were urged to register their trademarks promptly. The cost of registration was stated to be about \$6 per country, per year. There have been no lawsuits conducted in any of the Latin American countries, they were warned, to recover a mark that has been stolen in which the cost has been less than the cost of registration in all of the countries in the southern continent combined.

Press Relations

The establishment of better press relations was predicted by Frank B. Noyes, president of the Associated Press, who told of recent arrangements just completed whereby the largest South American newspapers will for the first time in history take the Associated Press service. This, he stated, should insure a better understanding of the habits and businesses between the two countries. More than 18,000 miles of cables have been installed between New York and Latin America, according to John L. Merrill, president of the All America Cables, who cited this as another connecting link between the continents.

South American papers, it was stated, have been subscribing to the European press for news service and for this reason have been influenced against American products and in favor of European commodities. Robert Barrett of the Bureau of Foreign and Domestic Commerce described the operation of the new press service between the U. S. and South America, stating that 3500 words a day are being sent over the cables, and also praised the branch of the Committee on Public Information, which was established in Buenos Aires during the war, and which he stated contributed three or four columns daily to the local newspapers, doing more than any other agency to acquaint the people with the progress of the U. S.

In answer to the question, "Will the U. S. hold its export trade gained in Argentine during the war?" Mr. Barrett said that it will hold a great part of the business, but that we can not expect much business from Argentine for the balance of this year.

Immediately after the armistice, he said, American manufacturers, who had been holding up orders to Argentine for many months, began to ship commodities to that country, with the result that a surplus of supplies has been received there. He praised the establishment of the two American branch banks in Buenos Aires which now allow American manufacturers to extend credits as freely as European competitors. He described the banks as being very successful with deposits over \$60,000,000.

Eighty-eight American firms, he said, are carrying stock in Buenos Aires and are consequently in a position to meet any and all European competition. His statement that the Argentine Republic now regards the U. S. in a more friendly light than any other nation was repeated by a number of Argentinian representatives, all of whom attributed this feeling to the motion picture business, which they stated has shown the American progress and ideals to Argentine.

The aid being given to industry by the business press of the U. S. was discussed by A. C. Pearson, president of the Associated Business Papers, who stated that the Webb-Pomerene bill, which "promises so much for foreign trade in the United States," was made possible largely by the co-operation of the business papers.

The business publications, he said, inform their readers of possible markets, of all trade news, of new designs, of the progress of the industries, and extend important advice and criticism, besides also functioning as important encyclopedias of knowledge through their advertising columns.

Capital Investments

Other discussions, including those by Charles M. Schwab, Frank A. Vanderlip, Senor Augusto Villaneuva of Santiago, and Senor Julio Zamora, Financial Agent of the Bolivian Government, told of the need for re-organization of Pan American business and of the duty of the U. S. to invest capital in Latin America to further the industrial and commercial relations between the two nations and to provide funds whereby the Latin American countries can pay for their exports from this country.

Other subjects discussed included the necessity of teaching Spanish in the schools of the U. S., the development of transportation in Latin America, the extension of better credit facilities to Latin American buyers, the improvement of the administration of consular offices and the revision of tariffs.

The next meeting of the Pan American Conference will be held in January, 1920, according to notice received from President Wilson during the last Convention.

CURTISS BUYS SERVICE PLANES

WASHINGTON, June 6—The Air Service has sold to the Curtiss Aeroplane & Motor Corp. 1615 JN-4D airplanes without engines, and 1100 Standard J1 planes without engines, for \$2,272,000, which is 12 per cent of the original value, which was estimated at \$22,500,000. The Air Service discontinued the use of the SJ-1 plane last summer.

TILTON BELT REPRESENTED BY CASSIDY

NEW YORK, June 11—Edward A. Cassidy Co., Inc., has been appointed manufacturer's representative and will act as the sales department for Tilton endless woven belt.

Air Service Seeks Inventions

Gasoline Gages and Tanks, Portable Hangars Among Devices Needed

WASHINGTON, June 7—The War Department Air Service is in need of certain devices and appliances and asks the assistance of inventors and engineers with regard to development of the following:

Gasoline tanks that will withstand a salvo of 15 shots fired at a range of 30 yd., the ammunition consisting of calibre 30, equally mixed, service, tracer, incendiary and armor piercing bullets, fired through the tank at the most vulnerable angle with fire occurring in 10 consecutive tests on as many tanks. The weight should be kept low and be not more than 75 per cent more than the usual standard weight tank. Information about previous experiments will be furnished if wanted. Air bag floats, landing skids, etc., are wanted to prevent a machine from capsizing when landing in water.

Portable hangars for field service as the present hangars made of canvas are unsatisfactory and leak and blow down. Hangars are wanted to hold at least four De Haviland planes with enough room in addition for mechanical work, and should incorporate necessary wiring for electric lighting and extension lamps.

Gasoline supply gages are wanted that are responsive, serviceable and accurate to the last half-gallon, with mounting on the tank.

Central electric power plant, a single generator and battery is sought that will furnish required power for the radio installation, heating and lighting, electric starter, ignition and the motor driven camera. This is also to include necessary transformers to supply these various apparati with the electrical energy needed in proportion and kind.

Some sort of engine driven plant is wanted so that the head resistance of the wind driven generators now used will be eliminated. A saving in weight is expected from the new type suggested. The plant is wanted for use on Liberty 12 and Hispano Suiza 300 engines.

Mobile cranking device to be mounted on a motor truck to be electrically driven and for use on planes not equipped with self starters, is desired, so it may be used at an aerodrome by being backed up on to the front end of any airplane and built with a flexible arm attached to the propeller. The electrical energy is then to be used to crank the engine and start it. When the engine picks up, the arrangement should be such that the device will be automatically thrown out of connection with the propeller.

FORSCHLER UNDER NEW COMPANY

NEW ORLEANS, May 19—Philip Forschler Wagon & Mfg. Co. has been bought by the Forschler Motor Truck Mfg. Co., Inc., with headquarters at 120 North Claiborne Avenue.

34 PER CENT OF AIR ENGINES AMERICAN BUILT

WASHINGTON, June 6—The A. E. F. Air Service received 10,464 airplane engines during the war and up to Nov. 30, 1918, of which 4153 were Liberty 12's. The Allies produced 6944 or 66 per cent of the total number, and the United States 3520 or 34 per cent.

Of the 2698 planes received at the front by the A. E. F. the Allies produced 75 per cent, France turning out 1825, England 206 and the United States 667.

Five hundred and nine American fliers lost their lives in action including training and accident casualties, as compared with 2680 British and 1945 French. Following is the table:

	Killed	*Wounded*	*Missing*	*Per Cent* *Killed*	*Per Cent* *Wounded*	*Per Cent* *Missing*
American	509	241	277	50	23	27
British	2,680	2,988	1,837	36	40	24
French	1,945	2,922	1,461	31	46	23
Total	5,134	6,151	3,575	35	41	24

From the beginning of the war to April 30, 1919, the Air Service condemned 1105 planes and 853 engines of all types as follows:

Primary training		*Advanced training*		*Service*	
Planes	861	Planes	211	Planes	33
Engines	713	Engines	129	Engines	11

Ten thousand five hundred and ninety-four service engines and 2457 service planes are included in the "active" class by the Air Service, which has inventoried its equipment, as against 10,636 obsolescent training engines and 2955 training planes, and 2540 obsolete engines and 2031 planes. Following is the complete inventory showing the active engines and planes which are considered worthy of use, the obsolescent which are used but will not be rebuilt or repaired when worn, and the obsolete which are no longer used:

	New	Used, but in flying condition	Out of commission	Total	Per Cent New	Per Cent Used, in commission	Per Cent Out of commission
Active							
Service engines	10,081	288	225	10,594	95	3	2
Service planes	2,127	167	163	2,457	86	7	7
Training engines	2,007	608	122	2,737	73	22	5
Training planes	773	980	488	2,241	35	44	22
Obsolescent							
Training engines	4,480	3,942	2,214	10,636	42	37	21
Training planes	539	1,804	612	2,955	18	61	21
Obsolete							
Engines	1,419	158	963	2,540	56	6	38
Planes	1,026	65	940	2,031	51	3	46

	Killed	Wounded	Missing	Per Cent Killed	Per Cent Wounded	Per Cent Missing
American	509	241	277	50	23	27
British	2,680	2,988	1,837	36	40	24
French	1,945	2,922	1 461	31	46	23
Total	5.134	6.151	3.575	35	41	22

Primary training		Advanced training		Service	
Planes	861	Planes	211	Planes	33
Engines	713	Engines	129	Engines	11

75 PER CENT SAVED ON CANCELLED AIR CONTRACTS

WASHINGTON, June 9—Contracts have been cancelled and suspended for the Air Service since the date of the armistice representing an original value of $130,000,000, liquidated at a saving of $95,000,000 or 75 per cent. The following table gives details of how the various items have been dealt with.

	Value of contracts liquidated	Per cent of suspensions liquidated	Amount saved on liquidation	Per cent saved on liquidation
Balloons and supplies	$4,067,558	42	$3,418,830	84
Airplanes and spares	7,707,455	5	6,152,083	80
Fabrics, lumber and metals	3,984,143	51	3,127,143	78
Engines and parts	102,501,838	38	76,119,701	74
Instruments and accessories	1,149,995	14	1,021,131	70
Chemicals and chemical plants	8,983,419	66	6,242,331	69
Miscellaneous	1,548,547	14	1,281,735	83
Total	$130,242,955	27	$97 361,955	75

PROJECTS FOR 11,350 MILES

WASHINGTON, June 6—Projects for improving highways totaling 11,350 miles to cost $108,295,329, and on which Federal aid amounting to $43,076,176 was requested, have been approved by the Bureau of Public Roads to date. This includes 1188 projects, of which 813 miles have been completed at a cost of $6,870,451, of which $2,692,491 was paid in the form of Federal aid by the Government.

AERIAL SERVICE IN ITALY

WASHINGTON, June 9—A regular air mail service has been started between Rome and Naples, Italy, with two trips daily from each city. An aerial line will be started between Rome and Palermo in the near future. The trip will take about 4 hours. This is one of the first international air routes that will complete a route between Rome and Constantinople.

NEW CONSTITUTION ADOPTED BY GAS ENGINE ASSOCIATION

CHICAGO, June 7—A new constitution for the National Gas Engine Association, which provided for subsidiary groups and for greater specialization in associational work, was adopted this week at its annual meeting here. Sections already formed are the following: Farm Engine Section, T. C. Menges, Associated Manufacturers Co., Waterloo, Ia., chairman; Oil and Stationary Engine Section, O. G. Deane, Muncie Oil Engine Co., Muncie, Ind., chairman; Tractor Engine Section, R. K. Schriber, H. C. Doman Co., Oshkosh, Wis., chairman; Accessory Section, Walter Brown, Webster Electric Co., Racine, Wis., chairman; Farm Light Plant Section, L. S. Kilholtz, Domestic Engineering Co., Dayton, Ohio, chairman.

About 20 farm light concerns were present at the convention and it was decided that instead of forming a separate organization it would affiliate with the Gas Engine association.

Lynn W. Meekins, of the Bureau of Foreign and Domestic Commerce, addressed the last general session on the possibilities of foreign trade. He considers China, Australasia and Siberia as the sections of the world offering the greatest opportunities. He gave the following figures on the shipment of internal combustion engines during the war to June 30, 1918:

Engines for military tractors, 23,500; kerosene engines, 15,000, principally to Canada, England, Australia and New Zealand; gas automobile engines, 35,800, principally to Canada, England and Argentina; korosene stationary engines, 27,000, principally to Canada, Australia England, Cuba and France; gas marine engines, 7,200, principally to Canada, England, British India and New Foundland; gas stationary engines, 3,300, principally to France, Japan, England and Australia.

LOCOMOBILE SUIT MOTION

NEW YORK, June 10—Attorneys for the National Automobile Chamber of Commerce to-day filed a formal motion that the suit against the Chamber brought by the Locomobile Co. be dismissed because the plaintiff had not stated a sufficient cause of action. This is the friendly suit filed by Locomobile Co. attacking the validity of the patent pooling department conducted through the Chamber. The pleadings allege that this arrangement is detrimental to the trade.

Andrew L. Riker, president of the Locomobile Co., has held several offices in the Chamber. The filing of this motion leaves the suit open to argument at the request of either side.

N. A. D. A. AGAINST CAR SEIZURE

ST. LOUIS, June 9—At the quarterly meeting of the directors of the N. A. D. A. here Saturday it was decided that the association should lend financial and moral aid in the fight the Georgia State Dealers' Association is making against the law which permits the seizure of a motor car carrying liquor, regardless of mortgage rights of the seller.

The test case has recently been decided adversely to the dealer in the Georgia Court of Appeals. It is planned to carry this case to the United States Supreme Court. The seriousness of this situation is in the fact that the entire country probably will be on a prohibition basis in the near future. A telegram received from the National Automobile Chamber of Commerce assured the N. A. D. A. of full co-operation by that body.

The seizure of these cars, when sold on partial payments, is becoming a considerable factor in the dealers' banking arrangements.

AFRICAN AGRICULTURAL SHOW

JOHANNESBURG, SO. AFRICA, April 23—The Johannesburg Agricultural Show, which is an annual event, closed yesterday with an automobile exhibit disappointing in many respects. The absence of European cars made quite a difference, and the show was not up to its usual standard.

Studebaker's new models were shown for the first time. The Essex made its debut. There were only two tractors at the exhibit, Fordson and the Austin of Birmingham, England. There was no plowing ground satisfactory for the demonstration close at hand but the Fordson gave plowing exhibits nearby.

United States Exports of Cars, Trucks and Parts, by Countries, During April, 1919

75 Per Cent Detroit Business Improving

In May 69.6 Per Cent Business Normal and Above—31 Per Cent Below

DETROIT, June 10—Approximately 75 per cent of all Detroit business is improving rapidly in volume and earnings. Approximately 19 per cent is stationary while only 6 per cent is on the decline. Figures obtained from representatives of every line of business during May show that 25 per cent of business is above normal; 44 per cent normal, while 31 per cent is below normal but slowly climbing.

Price uncertainty is the greatest obstacle facing manufacturing lines. This is especially noticeable in the metal industries due entirely to the steel situation. Continued advance in the price of all commodities is due to wage increases and is halting development and readjustment more than any other single influence.

Detroit's prosperity is reflected in her banking institutions, 23 of which gained $43,394,906 in total resources between March 4 and May 12. On May 12, banking resources here totaled $517,510,360, as compared with $474,115,454 on May 4. The prediction is that the next statement of Detroit banks will show a total gain in resources of at least $200,000,000. This opinion is based upon the belief that millions of dollars involved in war orders will be settled by that time and that considerbale foreign business is coming.

—

BRITISH IMPORT RESTRICTIONS

LONDON, June 9—Recent announcements from the Board of Trade on further relaxation of import restrictions contains some interesting information for American exporters.

Rubber tires are to be admitted at the rate of 50 per cent of the 1913 importations. This is more liberal than the admission of cars, which is based on 50 per cent of 7 months of 1913.

The restrictions on the importation of the following articles are to be removed: Motor car jacks and track jacks, files, bronze castings, (machine or phosphor bronze), foundry flasks, springs for the upholstery trade, friction clutches, flexible metallic tubing, rubber manufactures other than tires, boots and shoes and stationery articles.

The importation of the following articles is to be licensed only exceptionally as and when required: Portable shop cranes, electric hoists and steel pulley blocks, except Yale triplex electric hoists, which are to be rationed to regular pre-war importers at the rate of 100 per cent of 1913 importations, steel tanks, trolleys and trucks for warehouse and wharf, shaft bearings, shaft bearing boxes, blocks for shafting, shaft collars, shaft couplings, shaft hangers, shaft hanger frames, metal baths and fittings thereof, iron and steel welded tubes up to 2 inches in diameter.

The importation of the following articles will be licensed exceptionally as and when required: fire extinguishers, electrical measuring instruments of all kinds, excepting those with 4-in. dials and under.

It is also reported that bulbs for electric lamps will be admitted into Great Britain at the rate of 50 per cent of the 1913 imports, and dry cells and primary batteries, except those for pocket lamps will be admitted at the rate of 20 per cent of the 1916 imports, according to information just received by the War Trade Board.

—

Expansion Plans Reflect on Machinery Trade

DETROIT, June 10—Expansion plans of the automotive industry are flooding the Detroit machinery makers and dealers with new business. A situation rather slow and gloomy in February and March has given way to one of optimism in May and June, and every indication now points to more business than many firms will be able to handle.

During the month of May, many automotive concerns announced expansion plans, the results of which reflect directly upon the machinery trade. Some of the companies announcing their plans last month are: Detroit Seamless Steel Tubes Co., new plant, $3,000,000; Saginaw Malleable Co., plant additions, $275,000; Standard Parts Co., Flint, new plant, $350,000; Jordan Motor Car Co., Cleveland, new plant, $250,000; Kenosha Wheel & Axle Co., Kenosha, Wis., new plant, $500,000; General Motors Corp., new plants, equipment, etc., in Michigan alone, $30,000,000; Henry Ford & Son, Dearborn, and in other states, plants and equipment in Michigan and other states, $2,500,000; General Motors Corp., outside of Michigan but within the United States, $12,000,000; in Canada, $6,000,000; Goodyear Tire & Rubber Co., Akron, plant addition, $500,000; Studebaker Corp., South Bend, new appropriation, $4,000,000; Maxwell Motors Corp., for Canadian plant, $1,000,000. In addition at least $2,500,000 has been scheduled for plant additions and new equipment by the firms in Michigan.

—

ELCAR INCREASES PRICES

CHICAGO, June 9—The price of the 6-cylinder Elcar has been raised from $1,375 to $1,475. The 4-cylinder remains the same, $1,175.

	New Price	Old Price
6-cylinder	$1,475	$1,375
4-cylinder	1,175	1,175

—

CONTINENTAL MOTORS ADDS

MUSKEGON, MICH., June 7—Continental Motors Corp. will spend about half a million or more in making building additions to its local plant and in adding new machinery.

Profit Tax Encourages Building Operations

Money Going into Plant Additions and Improvements to Avoid Heavy Taxes

DETROIT, June 9—The excess profit tax, which is taking from 40 per cent to 75 per cent of the profits of local manufacturers, is the cause of the greatest industrial expansion in the history of the city. Profits spent in expansion, plant improvements, new equipment, etc., are non-taxable, and scores of manufacturers are putting the major portion of their money back into their business. In other words, the government is paying for 60 per cent of expansion projects, here and elsewhere, for if the money was not invested in improvements, etc., most of it would go to the government in taxes.

Increased Capitalization

Dozens of companies have increased their capitalization and have erected new plants. New factories are springing up everywhere. The investment in new plant units, improvements, equipment, etc., will run high into the millions. Many concerns are building homes for their workers. Since Jan. 1 approximately $1,500,000 has been invested monthly in new buildings, not to mention the establishments which have changed hands, involving an equal, if not greater, amount.

The automotive industry has not been slow in grasping every expansion opportunity. In fact, the industry has set the pace for the rest of the manufacturing field. This is shown by the remarkable expansion projects of General Motors and Studebaker corporations.

Since the government fixed the price of steel and that market became more or less steady, as far as the building trades were concerned, construction plans held in leash by scores of big companies were released. Steel prices are in no way checking building work here.

—

PACKARD WINS GEAR SUIT

WASHINGTON, June 11—The Packard Motor Car Co. is decleared to be originator of the spiral bevel gear axle in a decision handed down by the Court of Appeals of the District of Columbia, a court of last resort in such actions. The Gleason Works of Rochester, N. Y., was the contender in the suit. The decision rules that a Packard employee was the inventor of the machine and process of making the gears in 1912 and that in 1913 the Gleason works devised a faster machine than that used by the Packard Co.

The decision follows, by a few days, the purchase of the patent rights by the Gleason Works. There are now nearly 400 Gleason machines in operation, each having a capacity of 10,000 spiral bevel gears annually.

Slight Prospect of Trade With Europe is Hanch's Report

(*Continued from page* 1363)

had been the father of high protection, should come to France and tell her what duties she should place on American automobiles.

In defending France's present attitude with regard to automobiles Mr. Cezanne says:

"Concerning the requirements of motor vehicles I should like first of all to state that the French Chambre Syndicale des Constructeurs d'Automobile, having studied this question very seriously for some months, is firmly resolved that future necessary general interests of the country must be considered before the private interests of automobile constructors. This is the policy that has been followed during the whole war.

"I think you have been misinformed as to the extent of the requirements of the French clientele and I should like to give you correct details showing by incontestable figures these requirements are much smaller than the supplies which could be made either immediately by the French military authorities, who hold a very large stock of motor vehicles, or within a relatively short time by our French factories which are able to turn out a much greater number of motor vehicles than are required to supply the French market.

"In 1913 there were 90,959 touring cars in France, of which 48,512 were used for business or professional purposes. To these figures add 6000 trucks which, at that time, were amply sufficient for French requirements. This totals 100,000 vehicles.

France Doubles Trucks Since 1914

"During the war the Government requisitioned all the 6000 trucks and 40,000 touring cars. Due to truck purchases from foreign countries during the war, France has approximately doubled the trucks she had in 1914.

"It may be strange to you that a country like France, with good roads, should have so few touring cars in proportion to its population, one car for every 300 people, whereas the U. S. A. has one car for every 14 people. It is impossible to compare the two situations if we consider the distribution of population per square kilometer and the length of railroad lines in the two countries. The French population is much denser per square mile or kilometer and the railroad mileage per population is greater in France than in the U. S. A.

"From 70 to 75 per cent of the French population belongs to the peasantry living on the land and have not been owners of motor cars.

"Again, in America a motor car lasts 2 or 3 years, whereas in France a car is kept as long as possible by the owner.

"In France the tax is very high and there is little chance for reduction. The luxury tax is 10 per cent for the value of the car and applies to used cars as well. The annual tax on the 15 hp. car ranges from 170 to 500 francs, according to the locality. Gasoline is 5 to 6 times as expensive as in the U. S. A.

"For these reasons, circulation of cars in France cannot develop as rapidly as in the U. S. A. Further handicap exists in consequence of the reduction of private fortunes in France, due to the war, and the great increases that must be made in taxes and, as a result of these conditions, an estimated maximum of 25,000 to 30,000 cars will meet the immediate requirements and that the total number cannot exceed 135,000 cars.

"In 1913 the French factories produced 45,000 to 50,000 car chassis, 25,000 of which were exported. Since then French factories have developed in the manufacture of car material and within a relatively short time will be able to produce 120,000 cars per year in addition to trucks. This is the presumed requirements of the French clientele, which are not all equally urgent and could be made within a year if the French factories were main masters of the French market.

"In addition the French factories are supplemented by 25,000 vehicles which can be immediately released from the army in good condition, and 25,000 others which can be released after undergoing repairs. These alone would meet the most pressing requirements of the French people.

French Factories in Production

"French factories are already beginning to produce cars and production will increase during the next few months so that the French market will reach the saturation point before the end of 1919.

"From the moment the possibilities of French production will have, exceeded the requirements of the French market, and if the makers require export trade, will the automobile makers of the U. S. A. be disposed to open the doors of their own market to French cars, which doors they have kept so tightly closed for more than 10 years?

"I, therefore, come to the conclusion that French automobile constructors cannot subscribe to the proposition which you formulate. The manufacturers of the U. S. A. must know that if they were permitted to send large numbers of cars into France, simply because they have been more favored than their French colleagues during the war and are able to make deliveries, that would be dealing a mortal blow to the French manufacturers. This, I feel, is not their intention."

Writing on the subject of future duties on automobiles, Mr. Cezanne continues:

"I quite understand that you find the course even unjust that an American car coming into France to pay a duty of 45 per cent ad valorem, while an Italian car pays only 10 to 15 per cent. Permit me to say with all free candor, that for many years French cars going into the U. S. paid 45 per cent ad valorem while American cars coming into France were only taxed on a basis of 8 to 10 per cent. France found this treatment hard and unjust, the more so because French production could not be a danger for American production, the latter being so much greater.

"At one of the meetings you gave us to understand that there was not much chance of this duty being materially modified and yet, because you have fought beside us, you ask all of the Allies shall be treated on the same footing. It seems to me, and I feel sure that all my countrymen will agree with me, that if any steps are to be taken towards an equitable solution, the government of the United States should take the first step.

"The American automobile industry would be honored in our eyes by bringing the matter to the notice of their government, but it is not surprising that if we cannot have the same tariff for all the Allies, we urge upon the French government at least to apply to each of our Allies the same treatment they think proper to apply to us."

Exports of Automobile Tires from United States During April, 1919

McGUIRE CARLISLE SALES HEAD

STAMFORD, CONN., June 10—Clarence V. McGuire has been appointed general sales manager and advertising director of the Carlisle Cord Tire Co. Until now he has been vice-president of Van Patten, Inc., advertising agency. In entering the company he becomes a director of the organization and a member of the executive board.

—

Harold W. Woodworth, who has been in the Boston office of the Ahlberg Bearing Co., Chicago, will be in charge of the new office of the company at 511 Westminster Street, Providence, R. I.

—

Bruce E. Anderson, formerly with the Ideal Engine Co., has become general manager of the Lansing Body Co., succeeding Frank Thoman, who retires as manager but continues as a member of the board of directors.

—

R. S. McLaughlin, president of the McLaughlin Motor Car Co. and a vice-president and director of the General Motors Corp., has been elected president of the newly organized General Motors of Canada, Ltd., which has a capital of $10,000,000.

—

L. P. Helm, for two years in charge of production of the Olympian Motors Co., Pontiac, has resigned to become production engineer of the Chief Motors Corp., Port Huron, Mich.

—

J. H. McMillan, advertising manager of the Mueller Metals Co., Port Huron, Mich., has resigned, to take effect June 15. His future plans have not been announced.

—

Otto Bruenauer, formerly director of sales and engineering of the U. S. Ball Bearing Mfg. Co., Chicago, has resigned. Otto Bruenauer and Howard L. Spohn became identified with the U. S. Ball Bearing company in January, 1917, and with Walter H. Strom had charge of the plant. As a result of reorganization and changes in policy consequent upon the death of Walter H. Strom in January, 1919, Spohn resigned as commercial manager in May, Bruenauer's rssignation following. Spohn immediately returned to the Class Journal Co. Bruenauer's future plans have not been announced.

—

CARBURETER HAS NEW MAKER

CHICAGO, June 9—The Beneke & Kropf Mfg. Co. has succeeded the Findeisen & Kropf Mfg. Co. and will make the Rayfield carbureters formerly made by the latter concern. With the reorganization of the company, plans for the material expansion of manufacturing have been formulated. Henry Beneke, formerly vice-president of Hibbard, Spencer Bartlett & Co., has purchased the entire interests of Frederick Findeisen and becomes vice-president and treasurer of the reorganized company. O. F. Kropf remains with the company as active president, and E. A. Bates continues as director of sales and advertising.

Men of the Industry

Changes in Personnel and Position

REQUA RESIGNS AS OIL HEAD

WASHINGTON, June 6—Mark L. Requa resigned to-day as director of the oil division of the U. S. Fuel Administration. Mr. Requa's departure marks the disbanding of the oil division, which controlled the production and consumption of oil, including gasoline, during the war.

—

PARKS HEADS MAXWELL

WALKERVILLE, ONT., June 6—George W. Parks has been elected president and general manager of both the Maxwell Motor Co. of Canada, Ltd., and the Chalmers Motor Co., of Canada, Ltd.

—

L. E. Lyons, who for the past several months has been acting as sales manager of the B. F. Everitt Co., has resigned to return to the Sheldon Axle & Spring Co., with headquarters in Detroit.

—

William F. Jahnke, formerly a member of the city commission of Saginaw, is now connected with the General Motors Corp. in Detroit, being one of six men working out plans for the organization of a savings and investment department of the General Motors Corp.

—

UNGER HEADS RESEARCH SOCIETY

DETROIT, June 10—J. S. Unger, with the Detroit branch of the Carnegie Steel Co., was elected president of the Steel Treating Research Society Saturday evening, and L A. Danse, Cadillac Motor Car Co. secretary and treasurer, was chosen vice-president. Dr. John A. Mathews, Syracuse, talked on metallurgical achievements of America during the war and the new alloys devised and new methods invented. He declared that the broken parts of the racing cars which failed to finish in the Indianapolis 500-mile race May 31 should be examined by experts to determine the reason for breakage in order to secure the benefit of this knowledge for future construction.

—

TRACTOR SHOWS IN OHIO

COLUMBUS, OHIO, June 10—There will be four tractor shows in Ohio this year. The first will be held here, July 28-29, the second in Piqua, Aug. 1-2, third in Fostoria, Aug. 6-7, and fourth in Akron, Aug. 12-13. The demonstrations will be in charge of Prof. H. C. Ramsower, head of the agricultural engineering department of the Ohio State University.

WHITE PLANS NEW CAR

DETROIT, June 9—D. McCall White, formerly vice-president of the Cadillac Motor Car Co., has opened a temporary office in Detroit. He is actively engaged in getting out the preliminary designs for a new car which he is going to manufacture. The location of the plant in which it will be produced has not been definitely determined.

—

DORT MEN IN SOUTH AMERICA

FLINT, June 10—F. A. Petrie, director of sales of the Dort Motor Car Co., for the South American countries, sails on June 20 for Buenos Aires to establish export connections for the Dort car in Latin America. He is taking with him Vaughn Green, engineer and service expert, and four sample cars. He expects to visit Argentina, Uruguay and Chile and will make a careful survey of that field.

—

Lynn McNaughton has been appointed general sales manager of the Cadillac Motor Car Co., succeeding Earle C. Howard, who recently resigned. Mr. McNaughton has been with the Cadillac sales organization for 14 years, and assistant under Mr. Howard since 1913.

—

B. V. Unwin, until recently connected with the Commonwealth Brass Co., Detroit, has been appointed manager of the sales promotion department of the J. C. Wilson Co., Detroit.

—

F. W. McIntyre has been appointed sales manager of the Becker Milling Machine Co., Boston. For the past 16 years he was connected with the Niles-Bement-Pond Co., Boston.

—

O. D. Conover, formerly vice-president and chief engineer of the T. W. Price Engineering Co., New York, and production manager of the Ludlum Electric Furnace Corp., has resigned to become sales and production engineer on foundries and steel plants of the Austin Co.

—

SHEEPSHEAD BAY ENTRIES

NEW YORK, June 9—A program of four events, 10, 20, 30 and 50-mile race, is scheduled for the Sheepshead speedway June 14. Professional entries include:

Dario Resta	Resta special
Joe Thomas	Mercer special
Louis Chevrolet	Frontenac special
Ira Vail	Hudson special
Denny Hickey	Stickel special
J. M. Reynolds	Frontenac special
Dave Lewis	Meteor special
Tommy Milton	Duesenberg special
Ralph DePalma	Packard special
Rene Thomas	Ballot
Albert Guyot or Louis Wagner	Ballot

The 20-mile event is to be an invitation race for non-professional drivers. The two entries for this event received by the Contest Board of the American Automobile Association so far are:

W. T. Comerford	Stutz
Eddie O'Donnell	Duesenberg

Current News of Factories

Notes of New Plants—Old Ones Enlarged

BRIGGS & STRATTON WILL ENLARGE

MILWAUKEE, WIS., June 9—The Briggs & Stratton Co. will enlarge its productive facilities aproximately 100 per cent at a cost of nearly $500,000. Ground will be broken early this week for a 5-story fireproof factory building, 60 x 185 ft., duplicating the present factory, erected about three years ago. In addition, a new office building, laboratory and engineering building, 69 x 120 ft., 4 stories high, will be built. The new facilities will be available by Oct. 1.

The company also will take over the motor-wheel department of the A. O. Smith Corp., Milwaukee. The motor-wheel is a gas-engine attachment for bicycles. The working force will be enlarged to 1,000 or 1200 in three or four months.

Stephen E. Briggs, president and general manager, left last week for Europe to investigate market conditions for export. During hostilities, the larger part of the company's facilities were devoted to the manufacture of hand and rifle grenades.

ENGLISH COLUMBIA AGENCY

DETROIT, June 6—The Columbia Motors Co., Detroit, has engaged Stanley Watson Inc., London, Eng., to take the agency for the Columbia car abroad.

PERFEX TO DISMISS BANKRUPTCY

MILWAUKEE, WIS., June 9—A petition seeking dismissal of involuntary bankruptcy proceedings filed March 28 against the Perfex Radiator Co., Racine, Wis., has been set for hearing on Wednesday, June 18, by Judge F. A. Geiger of the Federal Court at Milwaukee. The plant has been continued in operation under the direction of Julius J. Goetz, receiver, since proceedings were instituted.

DIVIDENDS DECLARED

The McCord Mfg. Co., Detroit, quarterly dividend, 75 cents, payable July 1 to stockholders of record June 25.

Pierce-Arrow Motor Car Co., Buffalo, quarterly dividend, 2 per cent, payable June 14 to stockholders of record May 31.

CLEVELAND, June 11—The Cleveland Tractor Co. will increase its capitalization $1,980,000. Stockholders will be given first opportunity to subscribe to the new stock. A stock dividend of 10 per cent was also declared, and an initial quarterly dividend of 1½ per cent beginning July 1, thus placing all the Cleveland stock on a 6 per cent basis.

Allis-Chalmers Manufacturing Co., Detroit, regular quarterly dividend, 1¾ per cent on preferred, and ¾ per cent on account of accumulated dividends on preferred, both payable July 15 to stockholders of record June 30.

Stutz Motor Car Co., Indianapolis, regular quarterly dividend, $1.25 a share, payable July 1 to stockholders of record June 23.

INTERNATIONAL HARVESTER BUYS PLOW

CHICAGO, June 9—The International Harvester Co. has purchased the Chattanooga Plow Co., maker of chilled plows. The Chattanooga Plow Co. was formed 40 years ago and is being operated by the founders. Its plant covers about 3½ acres of a 7-acre site. The line of horse and power cane mills established by the Chattanooga company will be continued by the Harvester company.

PLANS FOR 150,000 FORDSONS

DEARBORN, June 6—Henry Ford & Son plans to produce approximately 150,000 tractors during the fiscal year commencing June 1, 1919. The plant has been in operation 14 months and on May 1, the date it closed down for inventory, it had made 53,078 tractors. Inventory work was completed June 1 and the company is back in production. Approximately 100 tractors were run daily this week, and before the middle of June the daily output will be between 300 and 400 machines. Orders have been received from France, England and Belgium for 1000 tractors.

NORTHWAY MAKES 580 ENGINES DAILY

DETROIT, June 6—The Northway Motors Corp., one of the General Motors units, is averaging 580 automobile engines daily. The company is also making engines for the Sampson tractor. Approximately 400 engines are being turned out daily for the Oakland Motor Car Co., 150 for Olds Motor Works and 30 for the Cole Motor Car Co. It will be nearly one year before the building program, recently outlined for this company, goes into effect.

ONEIDA PRODUCTION DOUBLED

GREEN BAY, WIS., June 7—The Oneida Motor Truck Co. since the end of the war has more than doubled its production and increased its sales by 130 per cent. During May salesrooms were established at Baltimore, Denver and Sioux City.

FORD STREET CAR NEXT

DEARBORN, June 6—Within two weeks the first of Henry Ford's "street cars," with which he hopes to solve Detroit's transportation problem, will be in operation. The big gasoline vehicle is nearing completion at the Dearborn tractor plant. C. J. Hall of Los Angeles, Cal., is aiding Mr. Ford in designing and construction work.

MARTIN-PARRY MERGER

INDIANAPOLIS, June 9—The Martin Truck & Body Corp., York, Pa., and the Parry Manufacturing Co. of this city, both commercial car body makers, have merged as the Martin-Parry Corp. John J. Watson, Jr. is chairman of the board, and other directors are: Guy E. Tripp, Westinghouse Electric & Manufacturing Co.; James F. Shaw, Knauth, Nachod & Kuhne; F. M. Small, former president of the Martin Truck Co.; Robert I. Burr, S. C. Parry, Parry Manufacturing Co.; Walter R. Herrick, Herrick, Berg & Co., and George R. Walbridge, Bonbright Co., Inc.

COMPLAINT AGAINST PAN MOTORS

WASHINGTON, June 6—The Federal Trade Commission has issued a complaint against the Pan Motor Co., St. Cloud, Minn., and the president, Samual C. Pandolfo, charging him and the company with having sold stock worth $4,723,111 and deceiving the public by circulating false statements and unfair advertisements regarding the assets and resources of the company. They claim there were 54,000 recorded subscribers of stock of whom 39,000 have paid their subscriptions in full.

The commission complains that the Pan Motor Co. represented that they planned to manufacture passenger automobiles on a large scale but merely assembled 200 cars.

This is the first formal complaint issued by the Federal Trade Commission, and the defendants are ordered to file their answer by July 10.

REO MAKING 50 A DAY

LANSING, MICH., June 7—The Reo Motor Car Co. averaged 30 per cent more cars in May than the average production for the first quarter. The company is producing from 40 to 50 trucks daily.

800,000 KELSEY WHEEL SETS IN 1919

DETROIT, June 7—The Kelsey Wheel Co.'s 1919 output will be 800,000 sets of wheels, as against 690,000 in 1918. In addition to automobile wheels the company is now making automobile bodies and brake bands.

5 HINKLEY ENGINES A DAY

DETROIT, June 6—The Hinkley Motors Corp., after shifting from a 100 per cent war rating to a peace basis, got into production June 1 and is now running approximately 5 engines daily. The company expects to make 6000 engines this year and 15,000 in 1920. About 350 men are employed.

ACASON IN CAPACITY PRODUCTION

DETROIT, June 6—The Acason Truck Co. is producing from 20 to 23 trucks a day, which is plant capacity.

AUTO WHEEL PRODUCTION

LANSING, June 3—The Auto Wheel Co. is now approaching capacity production. The company is producing 450 sets of wheels daily.

Calendar

SHOWS

Aug. 30-Sept. 6—Minnesota. State Fair.

Sept. 1-6 — Indianapolis. Ind. State Fair, Cars and Accessories, Indianapolis Automobile Trade Assn., John B. Orman, Manager.

Sept. 13-20—Cincinnati, O. Ninth Annual, Music Hall, Cincinnati Automobile Dealers' Assn., H. K. Shockley, Manager.

*Oct. 9-19—Paris. Grand Palais, International Automobile Mfrs. Congress.

Nov. 7-16—London. Olympia Motor Car Exhibition—Society of Motor Mfrs. and Trades.

December — Brussels. International Automobile Mfrs. Congress.

Jan. 3-10 — New York, N. Y. Grand Central Palace, National Automobile Chamber of Commerce, S. A. Miles, Manager.

Jan. 24-31—Chicago, Ill. Coliseum, Cars; Drexel Pavilion, Trucks; National Automobile Chamber of Commerce, S. A. Miles, Manager.

January — New York. International Automobile Mfrs. Congress.

February — Chicago. International Automobile Mfrs. Congress.

Feb. 23-Mar. 6 — Birmingham, Eng. British Industries Fair.

TRACTOR SHOWS

June 9-12—Denver, Colo. Sectional Tractor Demonstrations, Denver Tractor Club.

July 14—Wichita, Kan. Automotive Committee of National Implement Assn.

July 28-29—Columbus, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 1-2 — Piqua, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 18-22—Aberdeen, S. D. Sectional Tractor Demonstrations.

October—Ottawa, Ont., Can. Interprovincial Plowing Match and Tractor Demonstration.

CONTESTS

June 12-13—Travers Isl., N. Y. Greenfield, Mass., and return. Inter-City reliability run.

†June 14—Sheepshead Bay, L. I. Speedway race.

July 4—Hohokus, N. J. Dirt Track Event.

July 4—Tacoma, Wash. Annual speedway races.

July 4—Atlantic City, N. J.—Airplane races—Aeronautic Convention.

*July 5—Cincinnati, O. Speedway.

*July 19—Uniontown, Pa. Speedway race.

*July 26—Sheepshead Bay, L. I. Speedway race.

*Aug. 15 — Middletown, N. Y. Dirt track event.

*Aug. 22-23—Elgin, Ill. Road race.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Sept. 27—Allentown, Pa. Dirt track event.

*Oct. 1—Cincinnati, O. Speedway race.

*Oct. 4—Trenton, N. J. Dirt track event.

*Oct. 11—Danbury, Conn. Dirt track event.

*Tentative dates.
†Sanctioned.

CONVENTIONS

June 12-14—Pittsburgh. Annual convention of American Drop Forge Assn. and Drop Forge Supply Assn., William Penn Hotel.

June 16-19—Detroit. American Society of Mechanical Engineers spring meeting, Hotel Statler.

June 23-28—Ottawa Beach, Mich. S. A. E. Mid-summer Meeting.

July 9-10—Buffalo. Motor and Accessory Mfrs. Assn. Mid-summer convention.

Sept. 22-24—Philadelphia. Annual Convention, National Association of Purchasing Agents. Bellevue-Stratford.

May 12-15, 1920—San Francisco. Seventh National Foreign Trade Convention.

January — Washington. Pan-American conference.

STROMBERG FINANCIAL REPORT

NEW YORK, June 9—The Stromberg Carbureter Co. of America, Inc., holding company of the Stromberg Motor Devices Co., has just published its annual report for the fiscal year ending Dec. 31 last. Net profits of $279,097 are shown, as compared with $318,819 of the previous year. The profit per share is $5.58, as compared with $6.37 in 1917, on the 50,000 shares of no par value.

The income of the Carbureter company consisted of $350,628, the net earnings of the Motor Devices company and $21,742 other income, a total of $372,368. The deductions are $70,392 for Federal taxes and $22,879 for other taxes and sundry expenses. In this report no provision is made for the 1919 taxes because the Federal rate was not known at the time the books were closed.

The Motor Devices Co. report shows sales for the year of $2,160,373 and operating profit of $384,781. The added income was $6,817, making total income $391,598. Charges of $40,972 were deducted for taxes, etc. The Carbureter company balance sheet shows:

Assets.	
Investment Stromberg Motor Devices Co.	$1,180,761
Cash	38,211
Liberty bonds	25,000
Notes receivable and accrued interest	201,400
Furniture and fixtures	238
Total	$1,445,610
Liabilities.	
Capital stock (50 000 shares without par value)	$250,000
Surplus	1,195,610
Total	$1,445,610

CARS AND TRUCKS FOR ARGENTINA

WASHINGTON, June 10—An additional field for motor cars and trucks has been opened in a section of Argentina as a result of the construction of a macadamized highway connecting the cities of La Plata and Bahia Blanca, which traverses the distance of Lomas de Zamora, Can Vicente, Canuelas, Monte, Las Flores, Azul, Olavarria, Laprida, Pringles and Tornquist. The first section of this road has been completed. La Plata is also connected directly with Buenos Aires by a macadamized highway. The new road, nearly 500 miles long, will link all of the border section with the ports.

TRADE-MARK LAW

WASHINGTON, June 11—A new trade-mark law in Honduras, effective Aug. 1, 1919, provides for a registration fee of $50 gold for each trade-mark. This increased fee will not apply to applications filed before Aug. 1.

JAPANESE REGULATIONS

WASHINGTON, June 6—New automobile regulations have been promulgated by Japan. Chauffeurs, who are required to be 18 years old, are divided into two classes, A and B, according to their qualifications as operators.

Those in class A may operate any kind of car and their licenses are good for five years. Chauffeurs in class B can also operate for five years on the same license, but only special cars or classes of cars.

The speed limits vary according to the width of the streets. On roads between 12 and 18 ft. wide, machines may run at the rate of 8 m.p.h., between 18 and 36 ft. at 12 m.p.h., on roads above 36 ft. in width at 16 m.p.h. Within the city limits machines must not travel on streets less than 18 ft. wide. They may run at a speed of 12 m.p.h. on streets between 18 and 36 ft. wide and on those wider than 36 ft. 16 m.p.h. is the limit.

FOREIGN TRADE OPPORTUNITIES

WASHINGTON, June 10—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has received requests for automobile or parts and accessories agencies of business from individuals and companies in foreign countries. These are listed below. For further information address the Bureau of Foreign and Domestic Commerce, Room 149, Customhouse, New York, specifying each Foreign Trade Opportunity number on a separate sheet of paper.

Mexico—Cars, motor trucks and accessories. No. 29 504.

Philippines—Cars and tires. No. 29,217.

Australia—Accessories and pressed steel grease cups. No. 29,524.

Belgium—For 3 firms sale of trucks, with trailers, 1½ to 3 tons, small agricultural machinery, tires, solid and pneumatic. No. 29272.

Belgium—Small cars, trailers, trucks and motorcycles. No. 29274.

Switzerland—Engines, trucks, tractors. Correspondence may be in English. No. 29280.

Catalogs with price lists of medium and high grade cars. Correspondence may be in English. No. 29313.

Spain—Cars. No. 29331.

LITHUANIA MARKET FOR CARS

NEW YORK, June 7—Lithuania, which has been freed from all export restrictions by the War Trade Board, offers a new field for American cars. It is a rich agricultural country organized into co-operative enterprises, which make it possible for her to buy on a large scale, according to a bulletin distributed by the New York office of the Lithuanian National Council. It is in need of proper motor equipment, including trucks, tractors and cars, offering a new market to the American manufacturer.

SHIP TO GERMAN AUSTRIA

WASHINGTON, June 9—Applications will now be considered by the War Trade Board for exportation of automotive products to German Austria.

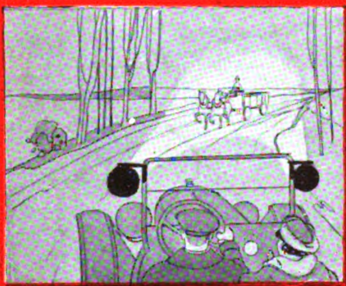
CUSTOM BILT NECESSITIES

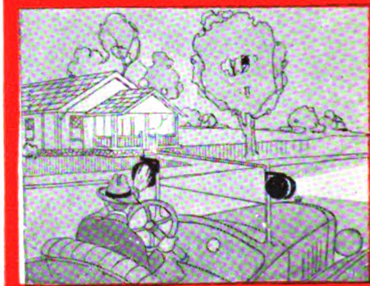


Every car should be equipped with *two* Stewart V-Ray Searchlights.

STEWART V-RAY SEARCHLIGHT LEADS THE FIELD

Only one worthy of the name **searchlight.** "Spotlights" are mere toys beside the sturdy Stewart. Projects intense beam of light 1000 feet. Is "custom-bilt" the Stewart Quality Way to outlast the car.

That's why more of them are now being sold than all "Spotlights" combined. ***Order your supply today.***

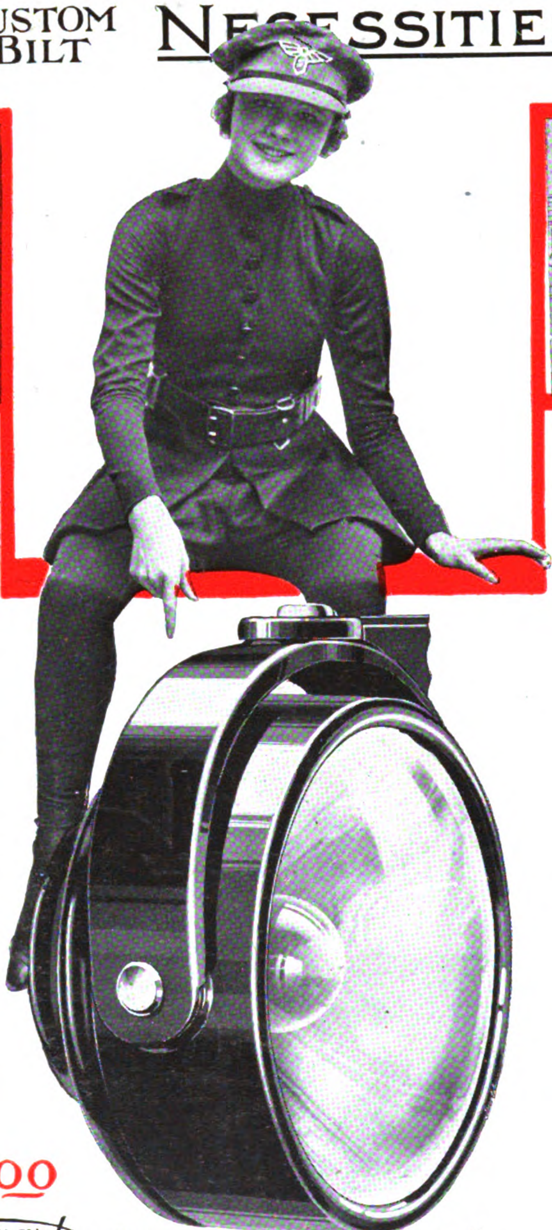


Intense beam of light is projected 1000 feet in any direction desired.

HERE'S NEW IDEA! IT WILL DOUBLE YOUR SALES

Sell every motorist **two** Stewart Searchlights instead of **one.** A new safety-first movement in vogue nationally. Motorists themselves started it. Thousands enlisting daily.

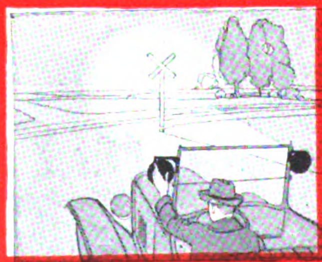
Searchlights do not blind oncomers, yet full strength, not diffused, light is always on road. Furnish safest illumination. Spread this idea. ***Double your sales. Reap the profits.***



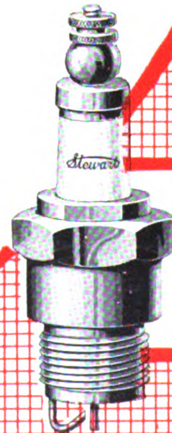
$6.00 Stewart V-Ray Searchlight

"More than a Spotlight"

Stewart Vacuum System $12.50



Picks out road signs, sharp turns, ditches and all danger spots.



Stewart Spark Plug $1.25

THE Stewart BIG TEN ARE ALL LEADERS IN THEIR CLASS

Non-Stop Transatlantic Flight Brings New Problems

Pilot of the Vickers-Vimy Voices Need of More Complete Meteorological Observations—Sextant and Compass Sufficient Guide Even in Fog

CAPT. JACK ALCOCK, who piloted the Vickers-Vimy airplane across the Atlantic in 16 hours and 20 minutes, is quoted as saying in an address at Galway, Ireland, that he expected that within a year airplanes would be carrying passengers across the Atlantic.

One of the first remarks made by Captain Alcock after his arrival in Ireland was: "We must have more complete meteorological observations. We were told in Newfoundland that the conditions were favorable. Yet within an hour we plunged into bad conditions, fog and a sleet storm."

As to the machine, Captain Alcock, who is a veteran British aviator, and Lieut. A. W. Brown, his American navigator, had little to say in the way of suggestions. Captain Alcock said that he had at no time pushed his engine and that the surprising speed was the normal engine work, aided by the winds, which were favorable throughout the trip.

The fuel supply, it appears from early reports, was sufficient to have completed a flight to London, had the aviators cared to continue to that point. Their landing at Clifden, Ireland, appears to have been due to a desire to make a good landing as soon as possible and not endanger the record of their trip by continuing. They had undertaken the flight in the London *Daily Mail* competition, which required only a landing on the Irish coast. In addition both men were greatly fatigued, due chiefly to the adverse weather conditions encountered.

Lieut. A. W. Brown *Capt. Jack Alcock*

Lord Northcliffe, owner of the *Daily Mail*, whose offer of $50,000 was directly responsible for this flight, as well as that of the ill-fated Sopwith machine piloted by Harry Hawker, sent a telegram of greetings to Captain Alcock. In this, Lord Northcliffe takes a remarkable view of the possibilities of transatlantic flying. His telegram reads:

"My Dear Alcock—A very hearty welcome to the pioneer of direct Atlantic flight. Your journey with your brave companion, Whitten Brown, is a typical exhibition of British courage and organizing efficiency.

"Just as in 1913 when I offered the prize I felt that it would soon be won, so do I surely believe your wonderful jour-

Front view

ney is the warning to the cable monopolists and others to realize that within the next few years we shall be less dependent upon them unless they increase their wires and speed up. Your voyage was made more quickly than the average press message of 1919.

"Moreover, I look forward with certainty to the time when London morning newspapers will be selling in New York in the evening, allowing for the difference between British and American time, and vice versa in regard to New York evening journals reaching London the next day.

"Then we shall no longer suffer from the danger of garbled quotations due to telegraphic compression. Then, too, the American and British peoples will understand each other better as they are brought into closer daily touch.

"Illness prevents me shaking you by the hand and personally presenting the prize, but I can assure you that your welcome will be equal to that of Hawker and his gallant American compeer, Read, whose great accomplishment has given us such valuable data for future Atlantic work.

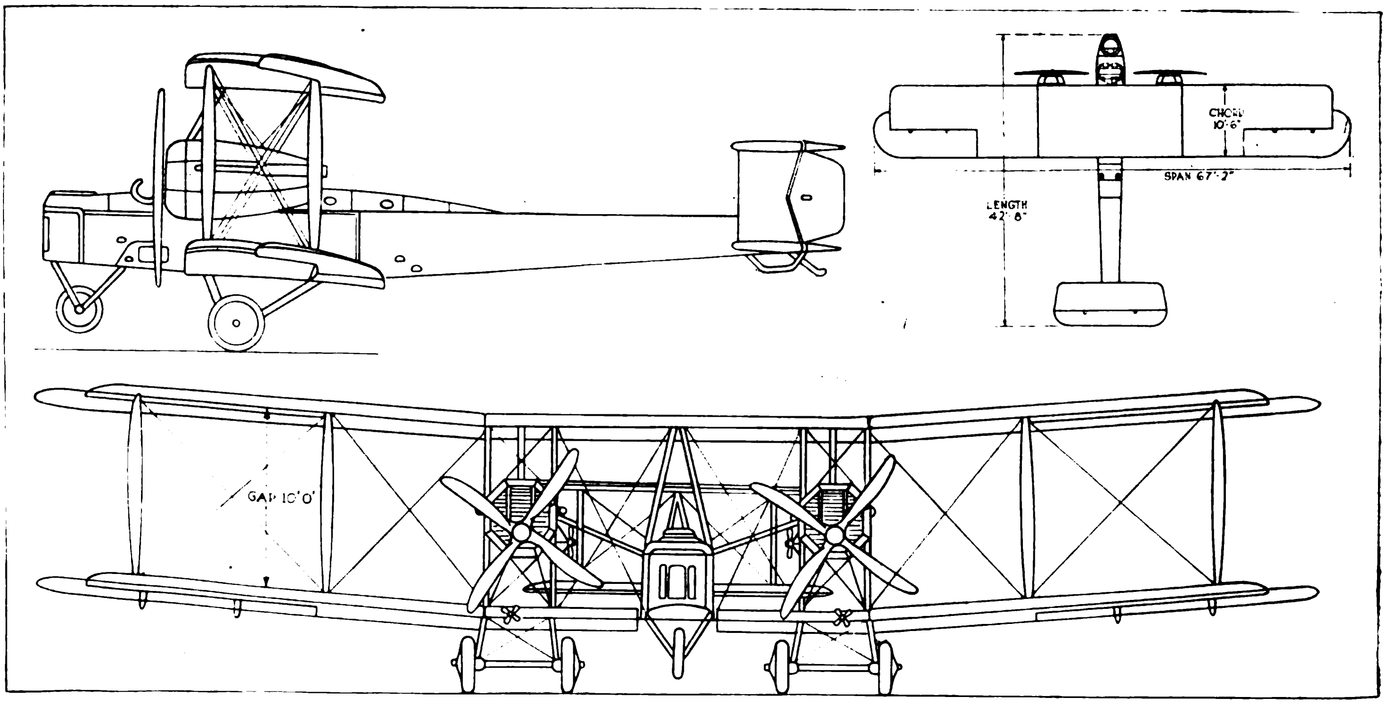
"I rejoice at the good augury that you departed from and arrived at those two portions of the British Commonwealth, the happy and prosperous Dominion of Newfoundland and the future equally happy and prosperous Dominion of Ireland.

"Yours sincerely, NORTHCLIFFE."

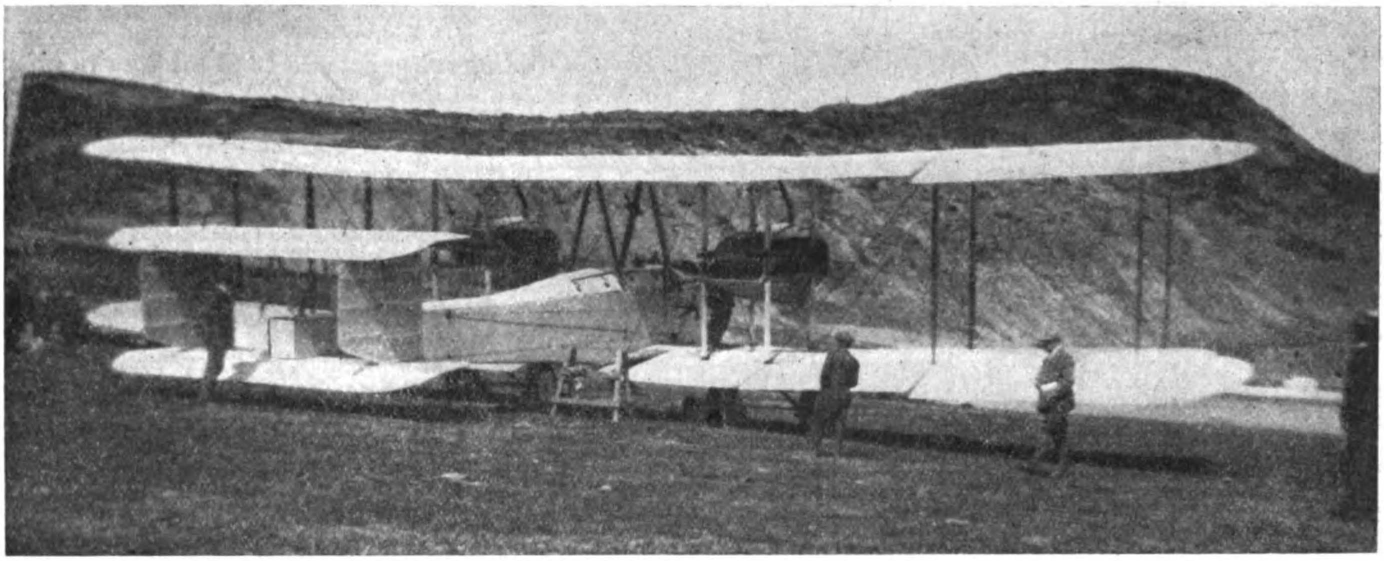
In later interviews both men spoke of the future as follows:

"The next time I cross the ocean," Captain Alcock said, "it will be in a flying boat. I foresee for the flying boat a great future, both as a passenger and commerce carrier."

On his side Lieutenant Brown remarked that the lesson gained was that marine navigation is entirely applicable to airplanes.



Side and front elevations and plan



Rear view

"There is little element of luck either in the success of the NC-4 or our flight," he declared.

"So far as weather was concerned, it could not have been worse in our case, for after the first hour we were smothered in fog until we landed in Ireland. Nevertheless, with only a sextant and compass, and a special device for determining the machine's speed and drift, we came through.

"And I am sure we could do it again."

The flight of the Vickers-Vimy was not in itself a surprise. The fact that the failure of the Sopwith machine had been due to incidental mechanical trouble—solder in the radiator—and the success of the American seaplanes in crossing the Atlantic had led the public to expect the success of this flight. The element of surprise was supplied by the speed, as apparently no one had counted upon the consistent aid of the winds for the entire journey.

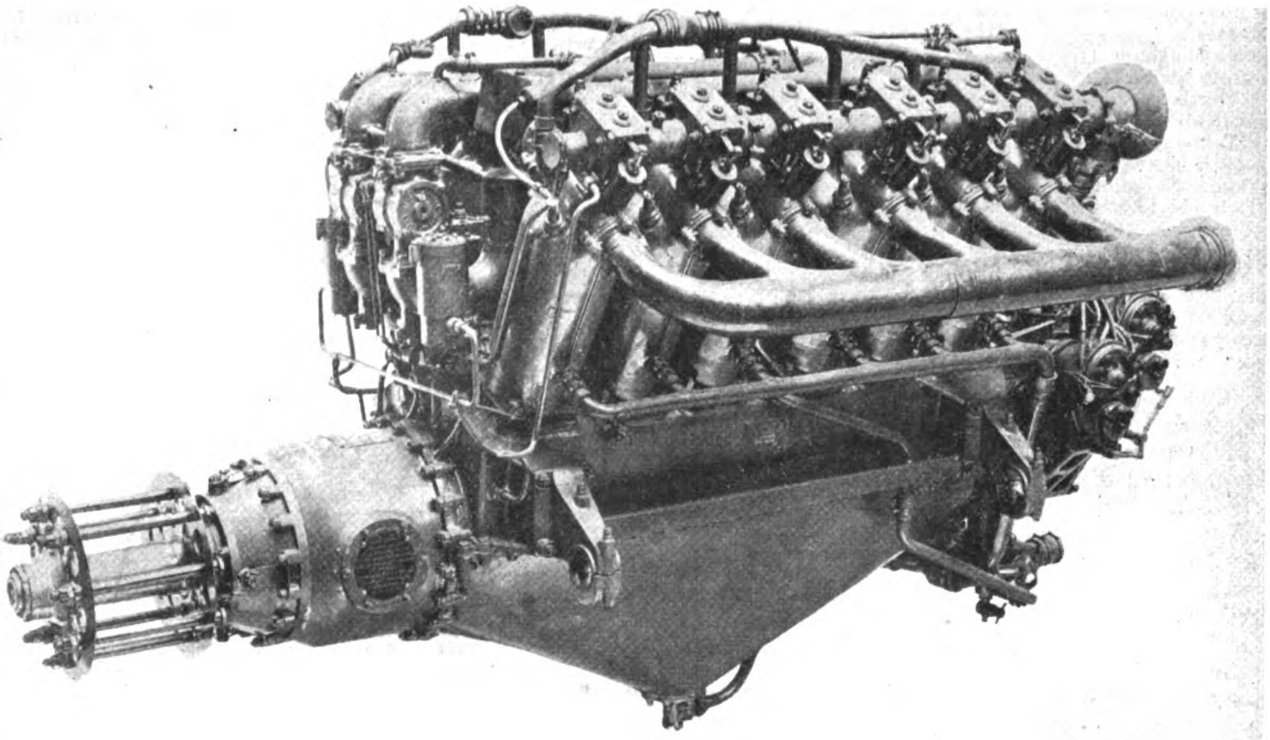
The exact record of the flight is:

Started, St. John's, N. F., June 14, 4:10 p. m., Greenwich time.

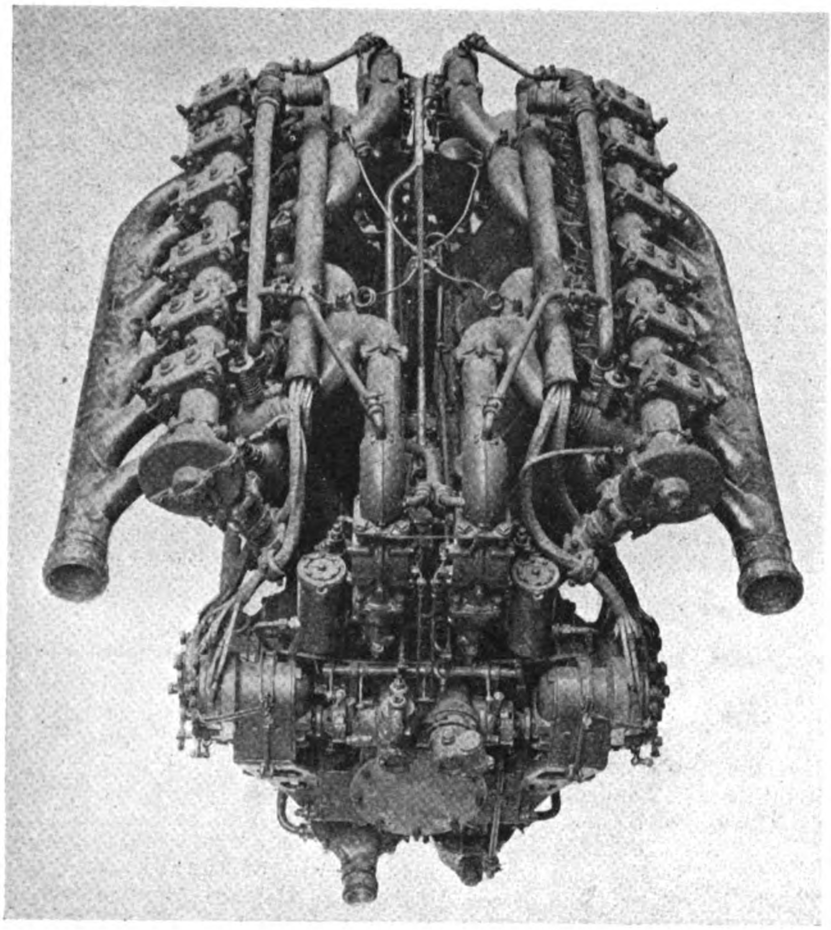
Landed, Clifden, Ireland, June 15, 8:22 a. m., Greenwich time.

Distance, 1900 miles, making an average of 120 m.p.h.

The only unfavorable feature of the Vickers-Vimy flight came at the finish, when Captain Alcock mistook a bog for a meadow and landed in it. The machine pitched forward on her nose, turned sideways, and was damaged to an extent that the plan for Captain Alcock to continue his flight to London was abandoned and the machine taken apart and removed there by freight. The two navigators made a triumphal trip to London by



Rolls-Royce 360-hp. Eagle engine with epicyclic reduction gear



Rear view of engine

boat and rail, being hailed at all stops as heroes and carried about on the shoulders of admirers.

The comparison of this flight, in a land plane built for speed, with the previous complete trip across the Atlantic by the American Naval sea planes, is:

Course	Date, May	Distance, Miles	Time, Hours	Speed, M.P.H.
Rockaway-Chatham (forced landing about 100 miles off Chatham)	8	345.45	5.45	59.87
Chatham-Halifax	14	368.42	3.51	97.87
Halifax-Trepassey	15	529.69	6.20	83.60
Trepassey-Horta	16-17	1,381.81	15.18	90.27
Horta-Ponta Delgada	20	172.72	1.45	99.83
Ponta Delgada-Lisbon	27	921.21	9.44	94.50
Lisbon-Mondego River	30	115.10	2.07	56.20
Mondego River-Ferrol	30	253.30	4.37	52.50
Ferrol-Plymouth	31	523.30	6.59	74.60
Complete Flight—				
Rockaway to Plymouth....	8-31	4,519.70	57.16	78.70
Transatlantic Flight—				
Trepassey to Lisbon.......	16-27	2,150.00	26.47	80.30

The Vickers-Vimy twin-engined plane was originally designed as a bomber. It has a wing span of 67 ft., a chord of 8 ft. 9 in., a gap of 12 ft., and an over-all length of 42 ft. 8 in. The chief modification required by the machine to fit it for the transatlantic flight consisted in replacing its bomb-racks and bomb-dropping gear with additional fuel tanks.

When "hopping off" from Newfoundland the Vimy carried 1090 U. S. gallons of gasoline weighing about 6000 lb., as well as 50 gal. of oil.

One of the outstanding features of the Vimy plane is the strength and elasticity of its construction, which are due to the use of seamless steel tubing. This type of construction extends from the nose to well behind the planes.

The Vimy has a sturdy double under carriage, with a two-wheeled chassis placed directly under each engine. Fully loaded the craft weighs a trifle more than 13,000 lb. Even distribution of eight separate tanks and a cleverly arranged feeding system whereby the fuel is consumed at the same rate from all eight not only insured a well-balanced plane but promised an "even keel" had the fliers been forced down on the surface of the ocean.

A gravity tank at the top of the fuselage was arranged to be emptied first so it could serve as a life raft any time after the first two hours of the flight, which period was necessary to exhaust the load of gasoline contained in that tank.

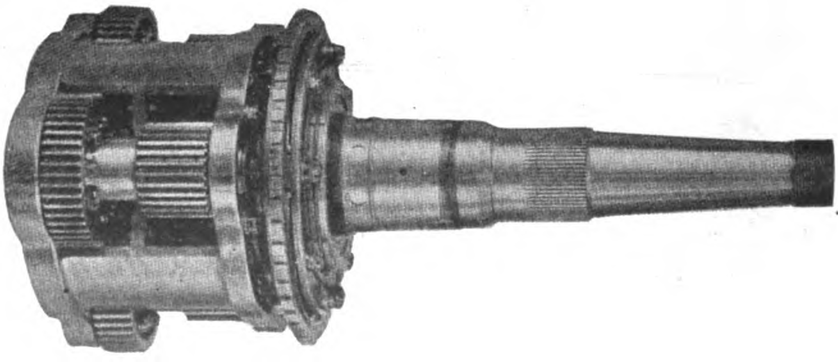
The Vimy's radio apparatus was the standard type used by the Royal Air Force, and was lent to Alcock by the British Air Ministry. It is similar to that carried by Hawker's Sopwith. The transmitting radius of this type of radio is placed at 250 miles. Messages can be received from a much greater distance.

The maximum flying speed of the machine in still air is about 100 m.p.h., but it was intended not to fly "all out," but to keep the engine throttled down to about 90 m.p.h. so as to obviate undue strains and also take advantage of the somewhat higher efficiency at this speed. Under these conditions it was figured that the Vimy had a flying range of 2440 nautical miles.

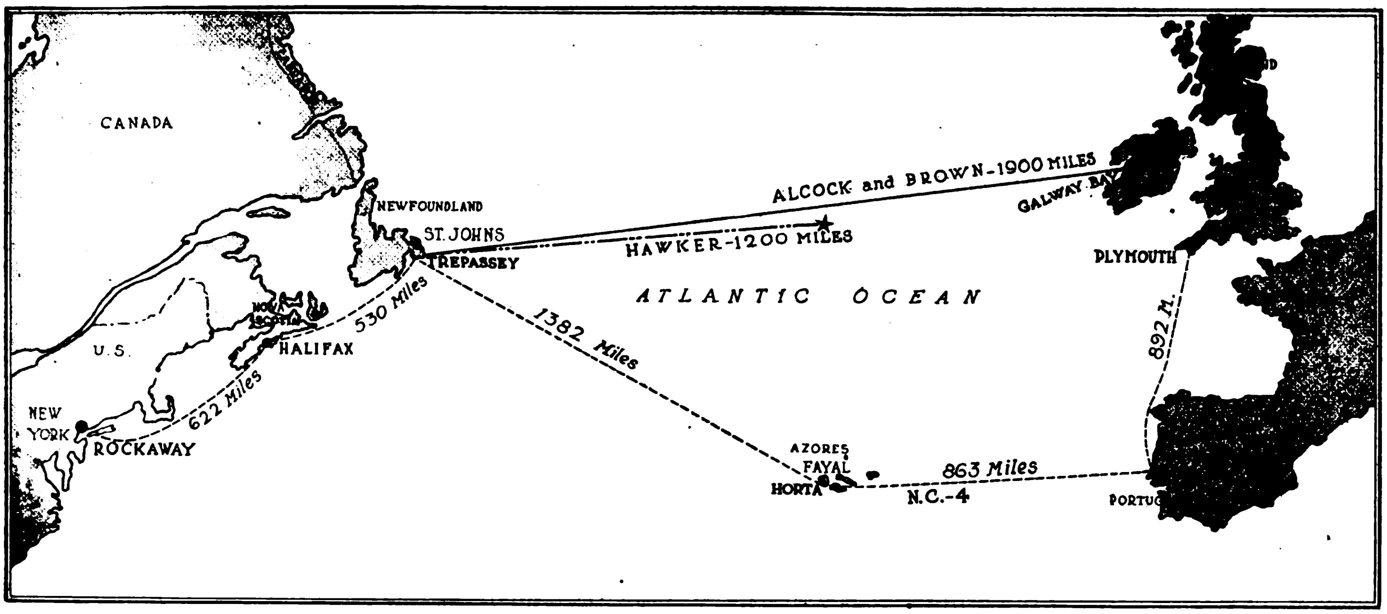
Capt. J. Alcock, D. S. C.

The pilot, Capt. J. Alcock, D.S.C., was born at Manchester, England, in 1892, and received his engineering training at the Empress Motor Works, at Manchester. He became interested in aviation in its early days and adopted it as a profession. He took the Royal Aero Club's flying certificate at Brooklands in 1912 and rapidly rose to the head of his profession, taking part in a large number of the early competition flights, among others the race from London to Manchester and return in 1913, in which he secured second place.

At the outbreak of war he immediately joined the Royal Naval Air Squadron and was assigned to Eastchurch as an instructor. Later he became the chief instructor of the Aerobatic Squadron. He did valuable work on the Turkish front, where he won the D. S. C.,



Epicyclic reduction gear



Routes followed by NC-4, Hawker and Alcock

and held the record for long-distance bombing raids. He was eventually taken prisoner by the Turks owing to an engine failure, and remained as such until the end of the war.

The navigator, Lieut. Arthur Whitten Brown, A.M. I.E.E., M.I.M.E., A.M.F.A.I.E., was born in Glasgow in 1886, and his parents were American citizens. He is an engineer by profession and received his practical training with the British Westinghouse Co., which is now allied with the Vickers Co. He received a thorough knowledge of surveying, and being interested in aviation, naturally devoted study to aerial navigation as applied to surveying. He enlisted in the University and Public Schools Corps in 1914, later receiving a commission in the Manchester Regiment, and served with the Second Battalion in France during 1915. He then transferred to the Royal Flying Corps as an observer and was wounded and taken prisoner of war in the same year. He was later interned in Switzerland, and repatriated in December, 1917, since which time he has been engaged with the Ministry of Munitions on the production of aero engines, and has put in a considerable amount of flying at home stations. He is also a pilot of some experience and has flown many types of machines.

Lieutenant Brown, after duration tests in the transatlantic "Vimy," considered he would have no difficulty in making a successful Atlantic flight. He intended to rely upon a system of navigation similar to that employed in marine navigation.

Preliminary Flights at Brooklands Airdrome

The preliminary flights were successfully carried out at Brooklands Airdrome, Surrey, by these two officers, who expressed themselves completely satisfied with the tests. The Rolls-Royce engines ran perfectly and the airplane left the ground with its load of 4 tons of gasoline and oil after running a very short distance on the ground.

The Rolls-Royce Eagle engine is a 12-cylinder machine with a bore of 4½ and a stroke of 6½ in. It is provided with a reduction gear which at a crankshaft speed of 1800 r.p.m. turns the propeller at 1080 r.p.m. At the normal speed the engine develops 360 hp., and its weight, including the reduction gear, but not including radiator, water, oil or fuel, is 877 lb.

The cylinders are machined steel forgings, fastened to the crankchamber by four bolts and having spherically shaped heads in which the valves are inserted in an inclined position. The valve ports are integral with the cylinder. Pressed steel water jackets are welded to the cylinder in two halves. It should be mentioned that a cylinder head with overhead valves is very generally regarded as the only reasonable form of cylinder-head construction for an engine working at very high mean effective pressure, to give a minimum of trouble from distortion, etc.

Articulated Pin Type Connecting Rods

The pistons are made of aluminum and are of the Zephyr type, which offers advantages from the points of view of strength, cooling, and lubrication. The connecting rods are steel forgings, machined all over, and are of the articulated pin type, that is to say, the main rod carries a pin on the big end, on which is pivoted the articulated rod, serving the other side of the engine. This type of construction makes for efficient lubrication and is an advantage from the point of view of longevity, because it permits of adjustment of the big end for wear should this become necessary.

The crankshaft is of the standard six-cylinder type, machined all over, and bored out on pins and journals to remove inactive material and to carry oil.

An interesting point associated with the crankshaft is that it forms a pipe supplying oil under pressure to all the working joints of the engine mechanism. It is fed with oil under pressure through the main bearings, and this oil is in turn fed to the connecting rod big ends, and thence up the pipes in the connecting rods to the piston pins. The oil from the crankshaft is also introduced into the epicyclic gear and completely lubricates all the parts of the gear. The oil which necessarily leaks from each end of each crankshaft bearing and connecting rod big end is flung from the cranks on to the cylinder walls, lubricating the latter freely. Oil is also fed up the connecting rods to the piston pins and articulated pins. The lubrication system of the engine is therefore what can be called a complete pressure system.

The oil is supplied under pressure from a geared pump at the rear end of the engine, which draws from an external oil tank, which is mounted in such a position that it is cooled by the air draft. An entirely separate portion of the same oil pump extracts the oil which drains into the crankchamber and returns it to the external

BLAZERS OF AIR TRAIL

1500—Jean-Baptiste Dante made flights with a glider of non-vibrant wings in Perugia, Italy.

1742—Marquis De Bacqueville used imitation flapping wings from house on Seine to garden of the Tuileries.

1842—Henson patented monoplane to be driven by steam engine. Wing span 140 ft.

1871—M. A. Penaud built toy model which flew 131 ft. in garden of the Tuileries.

1876—Penaud designed airplane with two propellers.

1896—Prof. S. P. Langley's steam-driven monoplane model flew over Potomac successfully for 3000 ft. at 20 to 25 m.p.h.

1896—Lillienthal flew biplane glider previous to fitting it with 2½-hp. engine; killed in flight.

1900—Wilbur and Orville Wright experimented with gliders with arched surfaces and adjustable rudder in front. Glided 600 ft.

1903—Dec. 17—Wright brothers fitted a biplane glider with 16-hp. engine, made first successful sustained flight in world.

1906—Sept. 13—Santos Dumont made first officially recorded European airplane flight.

1907—Oct. 26—Henry Farman, Englishman, flew Voisin 2500 ft. in 52 5/10 sec. in a straight line.

1908—Aug. 8—Orville Wright surpassed French records for duration, distance and height in flights in France.

1908—Oct. 10—Orville Wright made flight of 1 hr. duration with one passenger.

1909—July 25—Bleriot crossed the English Channel from Calais to Dover in 37 min.

1909—Sept. 29—Wilbur Wright flew around statue of Liberty.

1913—June—Brindejon flew from Paris to Warsaw stopping at Berlin, covering 933 miles in 11 hr. including stops.

1914—July—Successful trials of the "America," ordered by Rodman Wanamaker for transatlantic flight.

1914-1918—War period.

1919—Harry G. Hawker and Commander Mackenzie Grieve flew 1289 miles from St. John's, N. F., in an effort to make a non-stop flight to Ireland, when their Sopwith airplane was wrecked and the men rescued by a tramp steamer.

1919—Lieut. Commander Read and Navy crew, in the U. S. Navy airplane NC-4, made the flight from Rockaway Beach, N. Y., to Plymouth, England, 4519 land miles in 9 stages between May 8 and 31. The longest flight was from Trepassey, N. F., to Horta, Azores Islands, on May 16-17. The average speed for this entire flight was 78.70 m.p.h.

tank, after straining it to free it from dirt. In this way no oil is allowed to accumulate in the base chamber, where it would become heated up by conduction from the engine.

The crank chamber is made of aluminum castings and consists of upper and lower halves. The upper half is designed for great rigidity and its stiffness is further increased by the lower half, which is secured to it by a large number of bolts.

The drives for the camshaft, magneto and other auxiliary devices are all at the rear end of the engine. An air pump is normally mounted at the rear end and supplies air under pressure to the gasoline tank, on planes where pressure feed is used. Provision is also made for a speed indicator and for mounting a hand or electric starting gear. The water and oil pumps are also mounted on the accessories drive unit at the rear end of the engine. There is one camshaft extending across the tops of each row of cylinders, and this shaft operates both the inlet and exhaust valves through rockers. This valve operating mechanism is entirely enclosed and is fed with oil from a main lubricating system.

Ignition is by six-cylinder Watford magnetos, of which four are carried on each engine, so as to provide two entirely independent systems of ignition for each cylinder. Four carbureters are fitted, each supplying three cylinders through a branched inlet pipe. The carbureters are a special development of the Claudel-Hobson type, with adjusting means designed to take care of climatic and altitude changes.

Water is circulated by a single centrifugal pump, mounted at the rear end of the engine and delivering to the jackets at their lower ends through two pipes. Hot water is taken from the topmost point of the cylinders and conducted to the radiator through two manifolds.

During 1915 the Rolls-Royce company developed an epicyclic reduction gear which has since then been fitted to all of their engines. The question of the desirability of a reduction gear on airplane engines has been much discussed. Recent experiments have fully convinced the Rolls-Royce company that the use of a reduction gear largely increases the transmission efficiency of an engine and propeller; that is to say, much greater percentage of the available horsepower of the engine is utilized in propelling the plane. This leads to improved performance as regards both speed and rate of climb, and to an increased radius of action.

While the gain effected by reducing the propeller speed is not large on high speed airplanes in which the ratio of horsepower to total weight is comparatively high, it becomes very important in large machines which have less horsepower in proportion to weight.

The gain to be effected by the use of a reduction gear depends also upon the amount of energy lost through friction in the gearing. It is claimed by the Rolls-Royce company that with the reduction gear developed by it the frictional loss is very small and that there is, in consequence, almost invariably an appreciable increase in transmissive efficiency over an ungeared engine, even in machines of the highest flying speeds. The epicyclic type of gear adopted by the company is claimed to avoid the extremely heavy side loads on the crankshaft and crank chamber experienced with the use of ordinary spur gear sets.

This design of epicyclic gear has now been in use for four years as an aero engine reduction gear and has recently also been adopted for the Liberty engine. In the case of the Rolls-Royce Eagle engine the reduction gear adds less than 90 lb. to the weight of the engine, or less than ¼ lb. per horsepower.

Fuel and Rating Problems Discussed by Mechanical Engineers

Digest of Papers Read at Spring Meeting of American Society on Pertinent Automotive Topics

DETROIT, June 16—Papers of direct interest to automotive engineers are included in the program of the American Society of Mechanical Engineers Spring meeting, which opened here to-day. These papers deal with fuel, carburetion, airplane wings, airplane generators and engine design.

Members of the Society of Automotive Engineers were invited as guests.

The papers of principal interest to the automotive industry are: "A Suggested Formula for Rating Kerosene Engines," by D. L. Arnold, chief engineer of laboratories, International Harvester Corp.; "The Production of Liberty Motor Parts at the Ford Plant," by W. F. Verner; "Air Fans for Driving Electric Generators on Airplanes," by Captain G. Francis Gray, Lieutenant John W. Reed and P. N. Elderkin; "Standards of Carbureter Performance," by O. C. Berry. Following is a digest of these papers:

A Suggested Formula for Rating Kerosene Engines

By D. L. Arnold

A piston displacement of 13,000 cu. in. per min. is suggested as the standard for brake horsepower rating for kerosene engines by D. L. Arnold. At the present time there is no standard rating in use and as a result engines of the same bore, stroke and speed, or, in other words, the same piston displacement per minute, are given different ratings by almost all manufacturers. The conditions are such that many bills are now being introduced in the state legislatures, specifying how an engine shall be rated. If all these bills were to pass, each state might require a different rating, compelling manufacturers to furnish different name plates in each state. It is therefore suggested that the members of the Society of Automotive Engineers, co-operating with the mechanical engineers' organization, should adopt a standard rating for this type of powerplant.

The deriviation of the formulæ now in use is familiar to engineers, and it is, of course, well known that they are based on widely varying assumptions. In fact, these different formulæ give widely differing ratings for engines of the same piston displacement per minute. Reducing these formulæ to the common basis of piston displacement per minute per horsepower, the figure varies all the way from 14,000 down to 9000.

The formula suggested by Mr. Arnold is:

$$\text{Rated horsepower} = \frac{D^2LNn}{16{,}550}$$

This formula assumes that the engine is capable of developing one brake horsepower for every 13,000 cu. in. piston displacement per minute and still have a fair overload capacity, since the maximum possible output should be one brake horsepower per 11,000 cu. in. piston displacement per minute.

With a standard rating established there should also be a standard type of name plate, which includes both the horsepower and the speed at which this horsepower is developed. In other words, the plate should read: 16 hp. at 500 r.p.m., not merely 16 hp., or 16 hp. speed 1000 r.p.m., giving both rating and maximum speed of engine. In this way no doubt will be left as to what is meant.

Tractive Rating

In considering the internal combustion engine rating for tractors, the majority of manufacturers have followed the rule that draw bar horsepower should be considered as 50 per cent of the rating of the power unit. This is very conservative, but is very good considering the wide range of conditions. However, the data on the name plate should include the following:

16 Brake hp. at 500 r.p.m.
8 Drawbar hp. at 500 r.p.m. of the engine
Drawbar pull:
....lb., reverse speed at......miles per hr.
....lb., first speed at......miles per hr.
....lb., second speed at......miles per hr.
....lb., third speed at......miles per hr.
Drawbar pull and horsepower are on the average good footing.

Standards of Carbureter Performance

By O. C. Berry

Carbureter performance reports should be based more upon the actual accomplishments of the carbureter than on the engine performance alone. With this in mind it is possible to set up standards of carbureter performance which give a better knowledge of the carbureter than is obtained from the average run for this purpose.

The characteristics of the carbureter which should be known in giving expression to its performance may be

expressed as indicated in the following subdivisions:

a—The range of flow-rate capacities, or, in other words, the maximum and minimum number of cubic feet of air per minute that can be handled.

b—The richness of the mixture as affected by the rate of flow of the air through the carbureter, sudden changes in the rate of flow, and the degree of throttle opening.

c—The pressure drop through the carbureter at different rates of flow.

d—The thoroughness and uniformity with which the fuel and air are mixed.

e—The uniformity of the richness of the mixture furnished to the different cylinders.

f—The temperature and dryness of the mixture entering the cylinders.

g—The temperature of the combustion-chamber walls, particularly the piston head.

Considering these matters separately, in brief, it is found that the flow rate range is important in passenger cars, where great flexibility is desired. It is suggested that the flow-rate capacity of all carbureters should be stated definitely in cubic feet per minute, and this information should always accompany the statement of the size of the carbureter flange.

The air required by an engine may be computed by assuming that the air required per brake horsepower per minute will remain nearly constant, irrespective of the amount of gasoline used or the speed of the engine, assuming that the carbureter is adjusted so that the engine carries its full torque with wide open throttle. For the usual passenger car type of engine, with a compression ratio of about 4 to 1, this constant is about 2.1 cu. ft. per min. at full power. The air used when idling at any speed is almost exactly one-quarter of that used under full load at the same speed.

Richness of the Mixture

The richness of the mixture is expressed in pounds of gasoline per pound of dry air. With a dry mixture at half load and 1000 r.p.m., regular firing may be obtained with mixtures between 0.0575 and 0.12. The best efficiency under the same conditions accompanies a mixture of about 0.067, and the best power, 0.08.

Pressure Drop

It is impossible to obtain 100 per cent volumetric efficiency on the ordinary type engine. The drop in pressure should be measured at the throttle on the carbureter side. If designing engineers would insist on data showing the pressure drop through the carbureter necessary to give the desired rates of flow, carbureter manufacturers would soon publish guaranteed-vacuum-air-flow curves, thus making possible intelligent carbureter selection for a given service.

Thoroughness of Mixing

The best direct test of the quality of the mixing is to have the carbureter discharge into a glass-walled section between the carbureter and the manifold. The best dry mixtures appear as colorless and dry as pure air, while wet mixtures resemble a fog, and in most cases streams of liquid fuel are seen following a spiral path along the wall of the manifold.

Uniformity of Mixture

It is impossible to measure distribution accurately, but the results obtained by any given manifolds may be tested by removing the exhaust manifold and observing the flames from the exhaust opening. This can be done to best advantage in comparative darkness. By adjusting the carbureter for continuously leaner mixtures, the impoverished cylinders will be caused to miss, and then by gradually enriching the mixture the yellowish flame will indicate the cylinder with the rich mixture. Uniformity is, of course, the desired goal.

Temperature and Dryness

Often the temperature and vapor pressure are high, to maintain a dry mixture once it is established, but the time element is lacking and the mixtures are consequently quite wet. It is desirable to make the fullest use of the heat in the combustion chamber walls, piston head and compression, and to introduce the mixture into the cylinder as wet as possible, still being sure to have it dry before it is burned.

Temperature of the Combustion Chamber

When the mixture is dry as it enters the cylinders, or the fuel so well atomized that it remains suspended in the air and is entirely vaporized during the compression stroke, the heat absorbed from the combustion-chamber walls does not improve the carburetion, but decreases the power capacity of the engine without improving either its efficiency or the way it runs. These conditions, however, are rare. A considerable portion of the fuel usually enters the cylinders as a liquid which collects on the piston head. Under these conditions the temperature of the combustion-chamber walls, especially the piston head, becomes very important. The reasons for this may be explained as follows:

The piston head is usually at a temperature two or three hundred degrees above the cylinder walls. If the temperature of the walls is 200 deg. Fahr., the piston head will therefore be between 400 and 500 deg. Fahr. If the wall temperature is lowered to 100 deg. Fahr., the piston head temperature will drop to between 300 and 400 deg. Fahr. These temperatures apply to passenger car engines running under ordinary conditions. Several tests have been run at Purdue to determine the rate at which Red Crown power gasoline will evaporate from the surface of a hot iron plate. The maximum rate of evaporation seems to occur when the metal is at about 450 deg. Fahr. If the evaporation in ounces of fuel per square inch of metal per second be taken as 100 per cent at 450 deg. Fahr., then the evaporation at 400 deg. Fahr. is about 40 per cent, at 350 deg. Fahr. about 9 per cent, and at 300 deg. Fahr. about 1.8 per cent. It is therefore important that the jacket-water temperature be kept high when the piston head is depended upon to flash any considerable amount of liquid fuel into a gas. This conclusion is borne out by the engine tests. With the air entering the carbureter at 70 deg. Fahr. and the jacket water maintained at 110 deg., the engine would not fire regularly with any richness of mixture. When the jacket-water temperature was raised to 200 deg. Fahr., the engine would fire some of the richer mixtures regularly, and by raising the air temperature to 80 deg. Fahr. the engine developed full power and efficiency and would fire a wide range of mixtures.

The Production of Liberty Motor Parts at the Ford Plant

By W. F. Verner

This paper deals with the production of Liberty engine cylinders and connecting-rod crankshaft bearings as carried on at the Ford Motor Co.'s plant at Detroit. The contract made with the United States Government called

for 5000 engines, and these were to be produced at the rate of fifty per day of eight hours. To do this, important developments in the methods of manufacture were brought about by the production department.

One of these was the method of producing cylinders from tubing. Six operations were necessary, and the author describes them in detail. The methods employed to produce connecting-rod crankshaft bearings likewise resulted in a great saving of time. Twenty-one operations were found necessary for this work, and a complete description of each is given. The paper concludes with an explanation of the method of installing bearings in the upper and lower halves of the Liberty engine crankcase.

Air Fans for Driving Electric Generators on Airplanes

By Capt. G. Francis Gray, U.S.A., Lt. John W. Reed, U.S.A., and P. N. Elderkin

In this paper the authors briefly describe the method employed by the Radio Development Section of the War Department in testing air fans used for driving the electric generators usually installed on airplanes for radio communication. They also discuss at some length the various types of air fans and present numerous photographs and curves clearly illustrating the construction of the fans and their operating characteristics.

The difficulty of the problem lay in designing a fan which would turn at constant speed in the air streams of widely varying speed set up by the airplane in flight. The various types of fans tested were: Fixed blade fans of special blade shape; fixed blade fans with wind brakes centrifugally regulated; fixed blade fans using a friction clutch or a friction brake centrifugally regulated and pivoted-blade fans with pitch centrifugally regulated.

Tractor Brake and Drawbar Horsepower Rating

By R. O. Hendrickson

I ATTENDED a meeting of the Tractor Standards Division of the Society of Automotive Engineers, and, while we did not come to any conclusion in reference to satisfactory ratings, it is expected that same will be voted upon June 23, and I might tell you that the tentative suggestions in regard to this which were put forth by those present were not entirely satisfactory to me. The ratings recommended were briefly as follows:

$$\frac{0.7854\,D^2LRN}{13{,}000} = \text{Brake horsepower}$$

$$\frac{0.7854\,D^2LRN}{26{,}000} = \text{Drawbar horsepower}$$

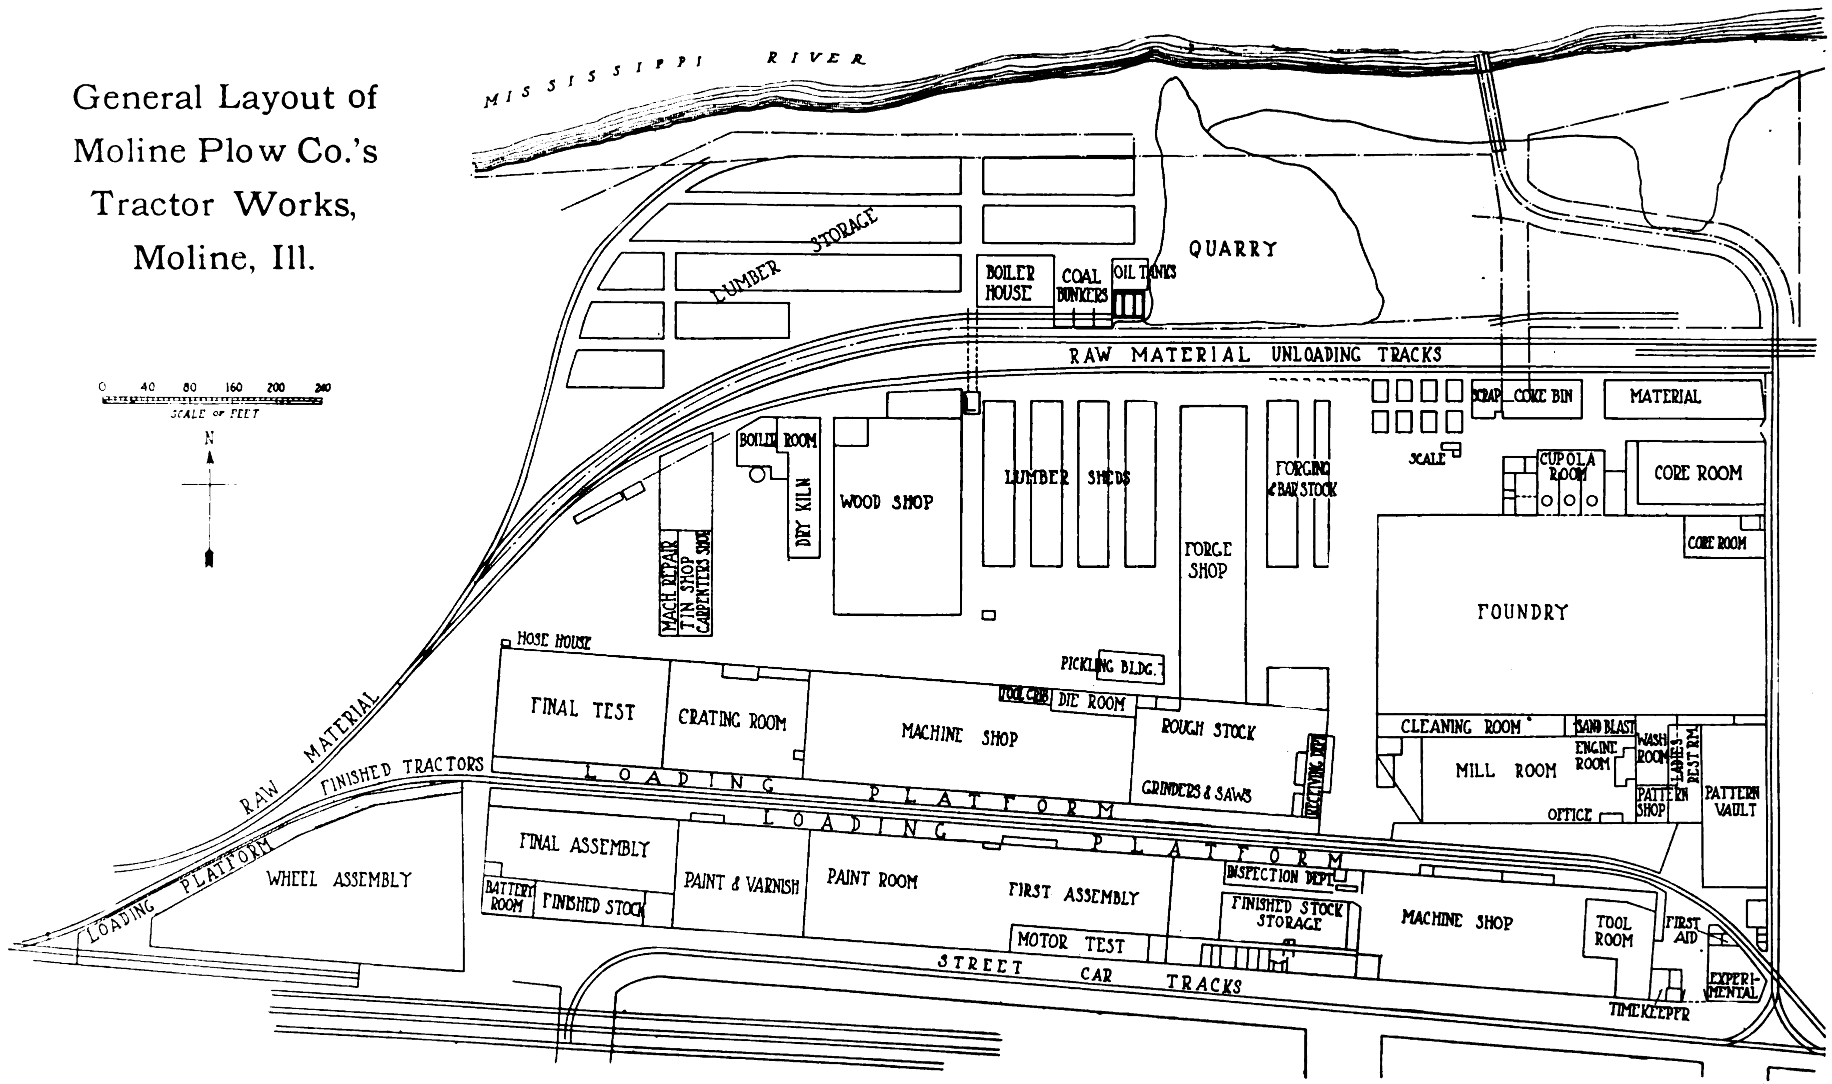
You will note that 13,000 cubic inches displacement per minute per horsepower is the constant used in figuring the brake horsepower, while the accepted A. L. A. M. formula for rating automobile engines is based on approximately 11,733 cubic inches displacement per minute per horsepower. The larger constant was thought desirable for rating tractor engines on account of the heavier work they are called upon to do and also on account of the fact that kerosene, which is largely used in tractor work, is supposed to develop less brake horsepower in a motor of a given size than is the case in the automobile where gasoline is used. Our experience, however, with kerosene is that the maximum power with a properly designed motor is almost exactly the same as when using gasoline. You will note that in calculating the drawbar horsepower they have considered merely doubling the constant, which would result in a drawbar power equal to 50 per cent of the brake horsepower.

My objection to the brake horsepower formula, as recommended, is that it does not fix a piston speed. It seems to me that, since within quite a wide range of speed the horsepower of a motor varies in almost direct proportion to the speed, and since the speed at which a motor is driven largely determines its life or endurance, a piston speed should be assumed in the formula, inasmuch as the wide variation in stroke of different motors and the fact that the arbitrary r.p.m. quoted by the manufacturer is used in the formula. In other words, the r.p.m. used in the formula should be based on a given number of piston feet traveled per minute. This would then give the formula a value which it certainly has not when the r.p.m. factor used is established according to the ideas of the engine maker. For a motor to endure and to be efficient it should not run at an excessive piston speed, nor at one too low. As the formula stands the engine maker is at liberty to state any r.p.m. he desires, which certainly would not be the case if the factor of r.p.m. were based upon 850 piston feet per minute, which we have found to be the most logical and satisfactory with our various sizes of motors for tractor work.

To make a long story short, we could use the formula outlined above and rate our motor either 25 brake horsepower or 50 brake horsepower, all depending upon what figure we decided to use for the r.p.m. If the piston speed were fixed at 800, 850 or 900 r.p.m. and the r.p.m. determined from this, then all makers of tractor engines would be rating their engines on the same basis, whereas as the formula stands it means nothing, at least that is the way it seems to me.

In regard to drawbar rating, this, it would seem to me, is almost impossible to establish, for several reasons as follows: First, the weight of the tractor in relation to the wheel diameter and width has a great deal to do with the rolling resistance of the tractor; second, the weight distribution has a great deal to do with the pulling capacity of the tractor as a whole; third, the weight of the tractor in relation to its motor horsepower has a great deal to do with the power available at the drawbar; fourth, the fact that the rolling resistance of a tractor requires all the way from 5 per cent to almost 100 per cent of the power of the tractor, due to soil conditions, is the worst of all, and it seems to me that to start off and rate a tractor motor with a formula where the piston travel is arbitrary according to the ideas of a man who rates the particular motor, and then to take 50 per cent of that as the drawbar horsepower, and in view of all the variable factors as outlined immediately above one has information of very little value when the calculation is finished. (*Continued on page* 1418)

General Layout of Moline Plow Co.'s Tractor Works, Moline, Ill.



While a certain amount of work is being done in this plant for the implement section of the Plow Works, most of it is devoted to tractor production. It is hoped to increase the daily production, which was about 55 tractors early this year, to about 150 by July 1

Production Features of the Moline Plow Tractor Works*

Two-Wheeled Tractors Produced According to Systematized Plan Similar to That in Automobile Plants—Shops Are Equipped with Modern and Exclusive Machinery, and Capacity Recently Was Tripled

By P. M. Heldt

FARM tractor plants employing production methods comparable with those in vogue in the automobile industry are very few in number. The reason is that the tractor industry is still very young, and there has been insufficient time to standardize and systematize. Tractor design, moreover, is not yet settled to any extent, and there is naturally considerable risk involved in investing heavily in tools and equipment that may be rendered obsolete by a change in design. A few manufacturers in the tractor field, however, have had the courage to go ahead and install the necessary equipment for the production of tractors on a large scale by the most up-to-date methods. One of these is the Moline Plow Co., whose tractor branch is at Rock Island, Ill.

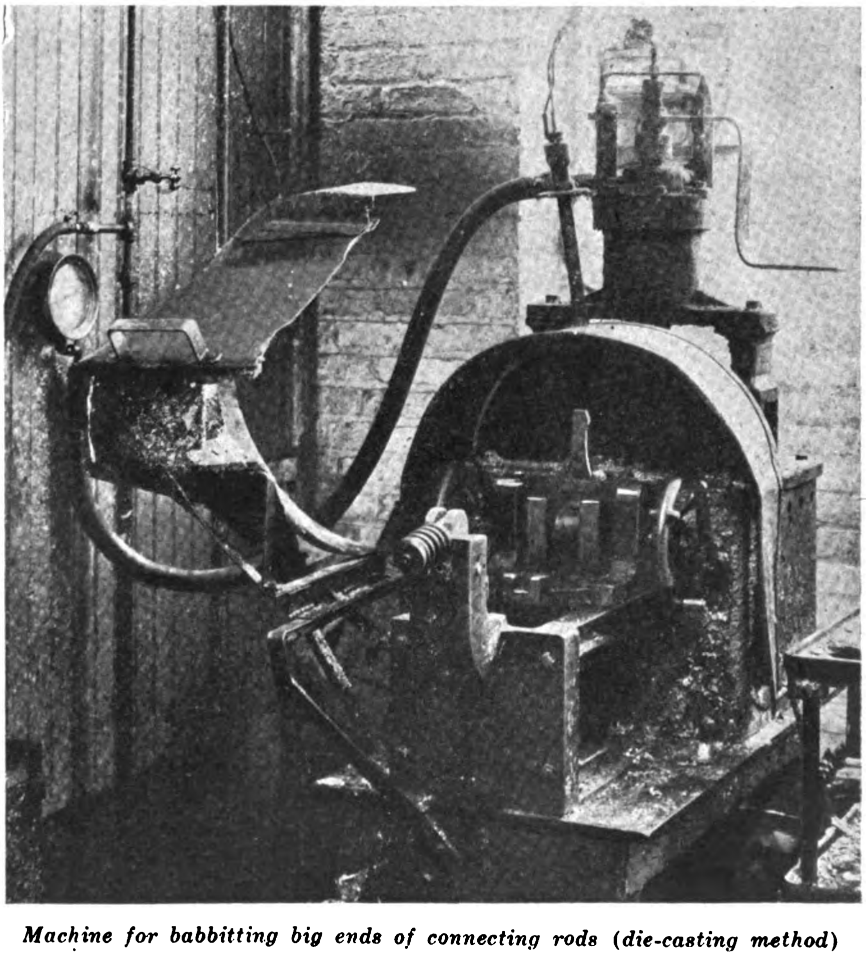
When the writer visited the Moline plant last March, the daily production was about 55 tractors. It was then planned to increase this to 150 tractors a day by July 1, without any material enlargement of the plant. This involved considerable rearrangement of departments and the installation of much new machinery.

The plant comprises a large and modernly equipped foundry, measuring 280 x 360 ft. The location of this with respect to the other departments of the works may be seen from the plan herewith. All raw material is received over a railway siding alongside of which are located a material storage shed, coke bins, scrap shed, etc. There are two rooms, one in one corner of the foundry building, the other one in a separate building. All of the simpler and lighter core work is done by girls, and this department is separated off from the main core room. There are benches extending in front of the core ovens, on which the core makers place the finished cores, whence they are transferred to the ovens. West of the main core-making room is a core storage room, and an overhead monorail extends into this room, so that heavy cores can be handled by power. A new spur from the Chicago, Milwaukee & St. Paul Railroad has just been laid down at the rear of the plant.

There are three cupolas in the foundry, and a total of 39 tons can be melted in each per day. The total number of hands in the foundry at the time of the writer's visit was 300, of which 90 were employed in the core rooms. The foundry is equipped with all the latest machinery devised for this class of work, including an electric sand cutter, moulding machines, strippers, etc. A good many castings are made in this foundry for the implement branch of the Moline Plow Co. The cast bull gears of the Moline tractor, which are one of the most important castings on the machine, are made by moulding machines developed by the concern's production experts. This is a hand ram roll over stripper for the drag. The teeth are made of dry sand and set into the mould, while for the cope an ordinary plate is used, which is lifted off with an air hoist.

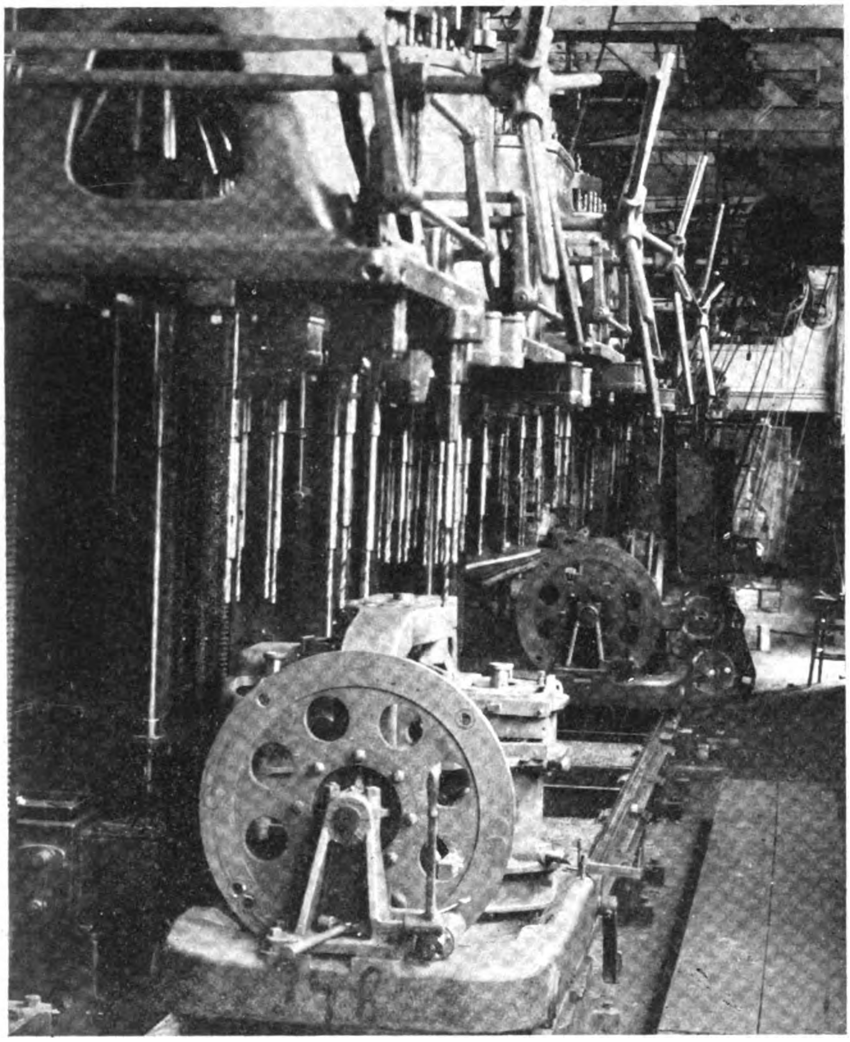
Two of the three cupolas are lined down to 68 in. in diameter, while the third is lined down to 58 in. Use is made of two No. 6½ and one No. 6 Root blowers.

A system for wetting the sand in the foundry at night has been introduced. The whole foundry is divided into floors, or sections, and over each floor there is a sign bearing the number of cubic feet of water required for

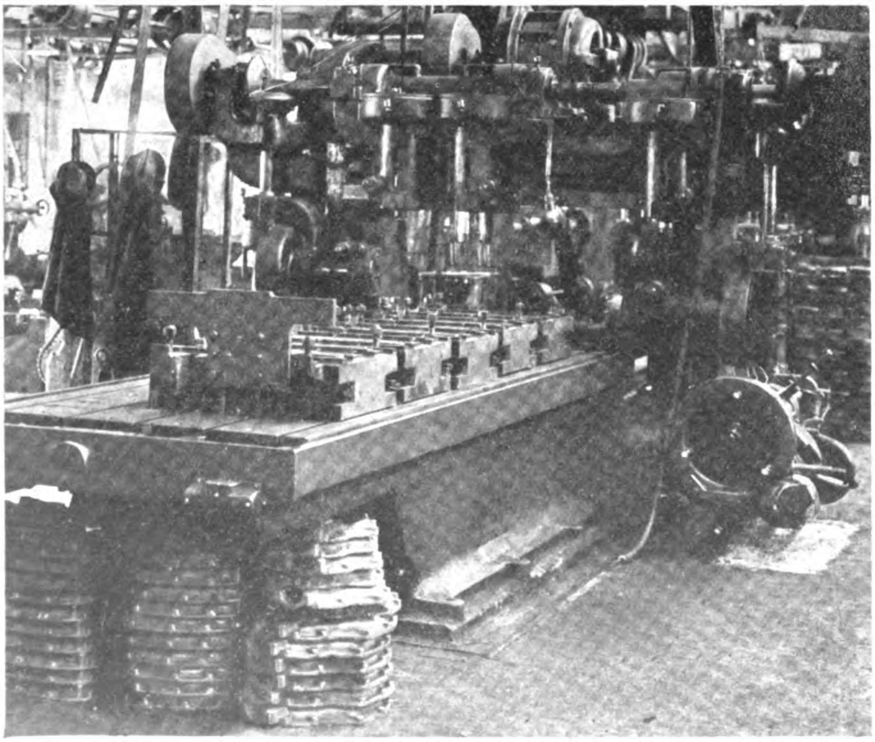


Machine for babbitting big ends of connecting rods (die-casting method)

*A continuation of this article next week will be devoted to the assembly and testing plant.



Railroad gang drill with tumbling jig in which transmission housing is handled while 100 holes are drilled in it



Ingersoll continuous milling machine in which six surfaces on the transmission housing are milled in one operation

it. One man waters the whole foundry. He carries a water meter at the end of a 50-ft. hose, on a harness, in front of him. Faucets are distributed throughout the foundry, so that this 50-ft. length of hose will enable him to reach any part. The water thus added to the sand exactly makes up for the evaporation during the day, not only for the whole foundry, but for each separate floor as well.

A Pangborne sand-blasting equipment is installed, and some of the castings are carefully cleaned, particularly the bull gears and transmission cases. The cases are first cleaned of all core sand, then tumbled, then chipped, then sand-blasted and ground, and finally they are inspected. A monorail system extends over the whole foundry, and the melted iron is handled in ladles having a capacity of 800 lb. each. Iron is melted at the rate of 15½ to 16 tons per hour. Castings are delivered to the mill room in two-wheeled handcarts.

The plant also has a small brass foundry, and at the time of the writer's visit two men were employed there. There are very few brass castings in the tractor, and most of the work done in this foundry is on patterns and aluminum plates. The foundry is of saw-tooth roof construction, and therefore has very good daylight.

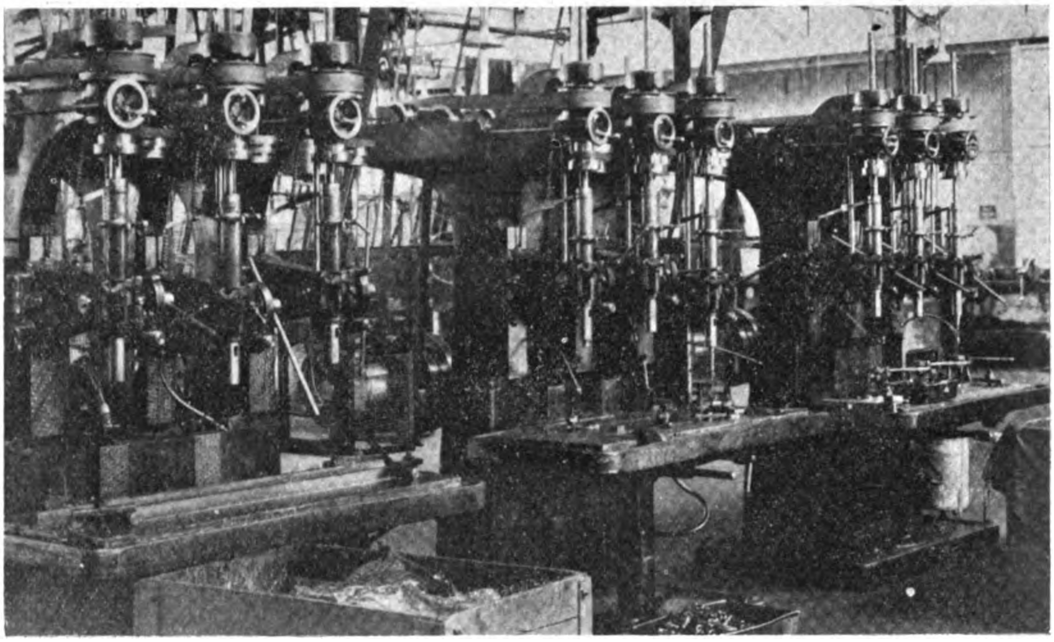
To the south of the foundry is the first cleaning room, where the cores are knocked out of the transmission cases. Next comes the mill room, where the castings are chipped and ground. At the eastern end of the mill room is the pattern shop, and over this is a girls' rest room. To the east of this is a pattern vault.

After the castings come out of the mill room they are stacked on a platform, alongside of a spur of the Chicago, Rock Island & Pacific Railroad.

There are two machine shops in the plant, referred to as shop A and shop B respectively. The most important part, in many respects, of the Moline tractor —the one on which the greatest number of machine operations are performed, and which forms the nucleus around which the whole tractor is assembled—is the transmission housing. The castings from which these transmission cases are made are received in machine shop B, and are faced on a Diamond surface grinder for the first operation. All of the machine tools in which this part is handled are naturally of the heavy type, and it is worth pointing out that there is a Richard-Wilcox crane over these heavy tools, so that the cases can be transferred from one tool to another by power. In addition, there are air hoists on swinging arms in this department.

After the first grinding operation the cases go on to an Ingersoll milling machine, which takes 9 cuts at one time. The cases are bored at the same time.

Some of the machine operations on the cases are as follows: First, the open end which bolts to the engine crank case is ground. Next, dowel holes are bored. In the next operation six plane surfaces are milled, and in the following operation four more surfaces are milled. Next, three holes are bored in Beaman & Smith horizontal boring machines. This operation comprises both rough and finished boring. Next follow two boring and facing operations, and after this the case goes to the drill presses.



Avery 3-spindle power drills for drilling and reaming (central spindle for reaming)

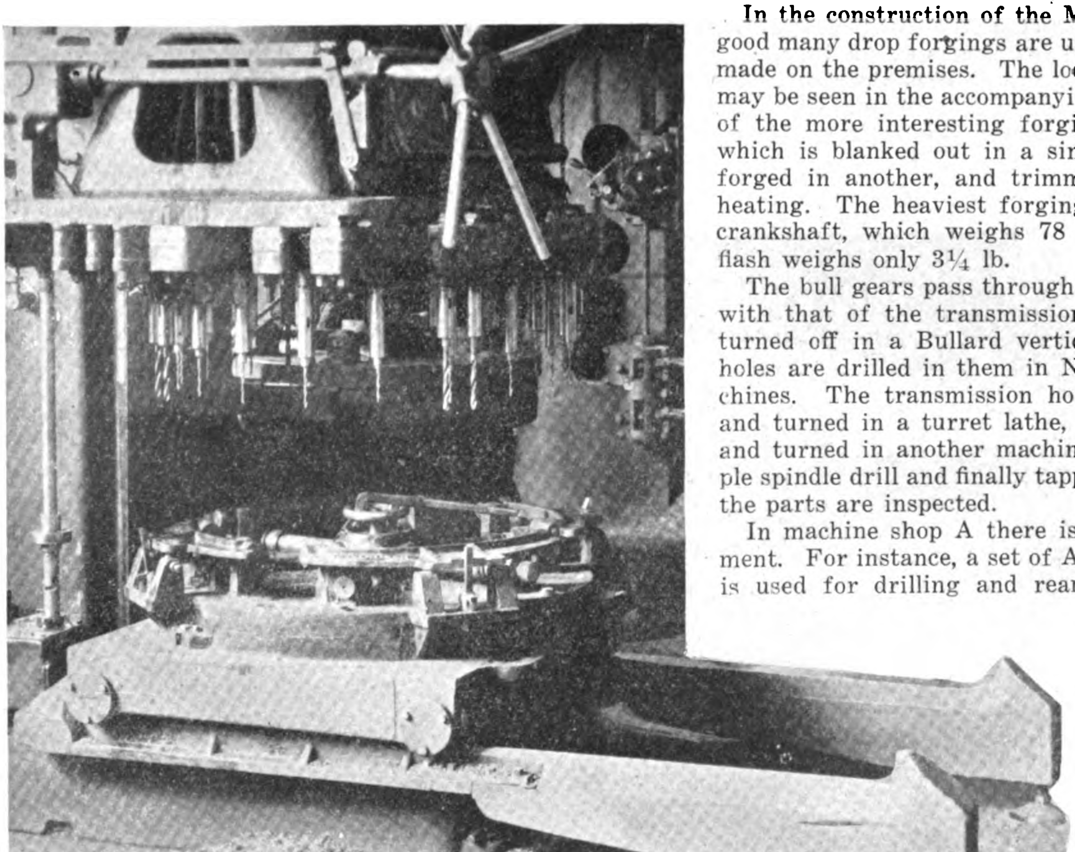
There is a total of 100 holes to be drilled in this part, ranging in size from 5/16 to 1 7/16 in. A set of four No. 30 Natco multi-spindle drills and two radial drills are used for this purpose, and the casing is handled in a tumbling jig, mounted on a truck on a track in front of the drills. It takes just 6 minutes to drill these 100 holes. All of the tapping required on the case is also done by power machines, the Hammond radial tapping machine being used. There is a gang of 6 of these machines, and the work done by them includes tapping 74 holes, reaming of one, and spot facing of two.

The drilling and tapping completes the machine operations on the cases, and they are then washed in soda solution, in which they are dipped. After drying they are painted inside by means of the spraying process. The cases are moved about the floor on electric trucks. There is an inspection of the cases between each pair of operations, and even between the drilling and tapping. After the cases have been cleaned and painted on the inside, they go to the assembling department.

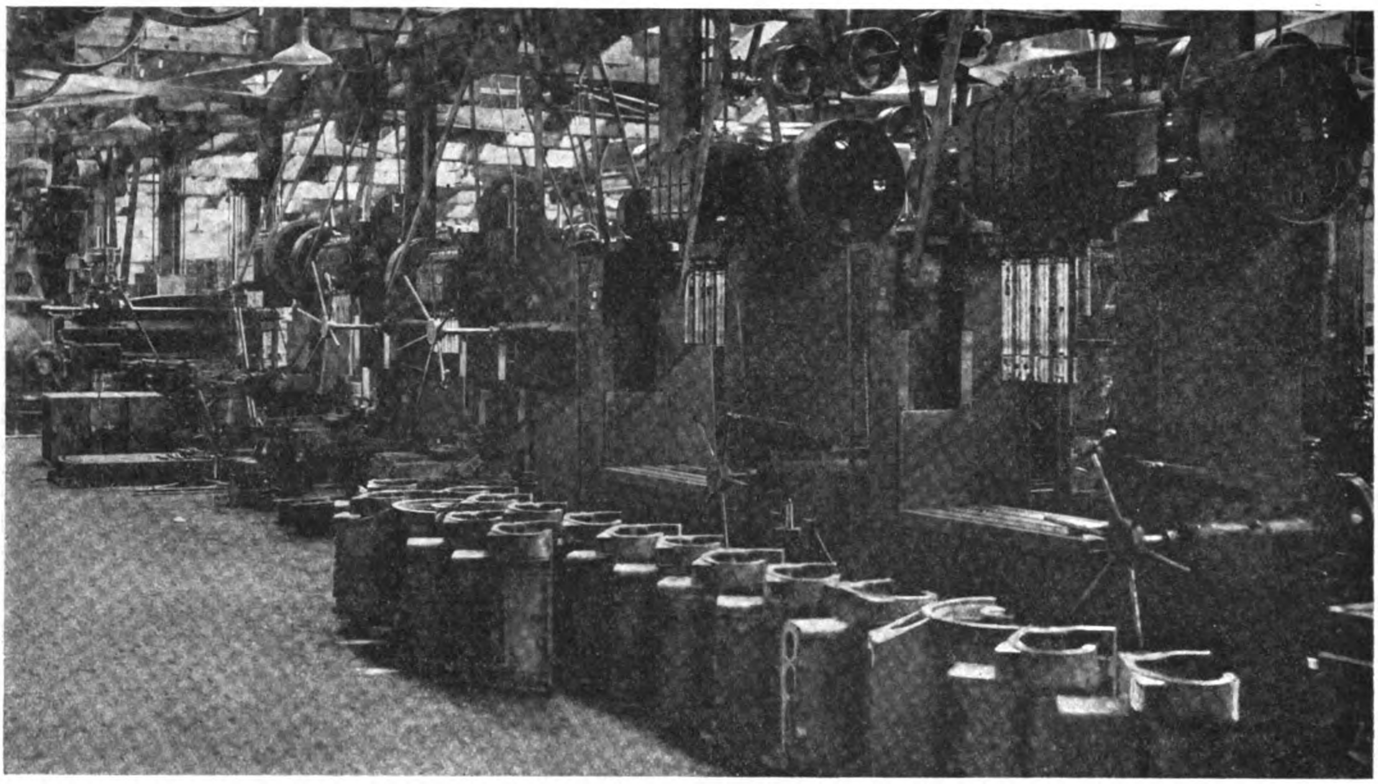
In the construction of the Moline Universal tractor, a good many drop forgings are used, and these forgings are made on the premises. The location of the forging plant may be seen in the accompanying plan of the works. One of the more interesting forgings is the clutch shifter, which is blanked out in a single piece in one hammer, forged in another, and trimmed in a third, all in one heating. The heaviest forging made in the shop is the crankshaft, which weighs 78 lb. in the rough, but the flash weighs only 3¼ lb.

The bull gears pass through the shop on a line parallel with that of the transmission cases. These gears are turned off in a Bullard vertical boring mill. Next, 26 holes are drilled in them in Natco multiple drilling machines. The transmission housing end is bored, faced and turned in a turret lathe, then bored, faced, reamed and turned in another machine, then drilled in a multiple spindle drill and finally tapped. At the end of the line the parts are inspected.

In machine shop A there is a great variety of equipment. For instance, a set of Avery 3-spindle power drills is used for drilling and reaming forgings, the center spindle being used for reaming. Next to these drills there are several Lapointe broaching machines, used for broaching key holes. One operator attends two of these broaching machines, while in the



Multiple spindle drill and jig used for drilling bull gears



Four-spindle cylinder boring machines

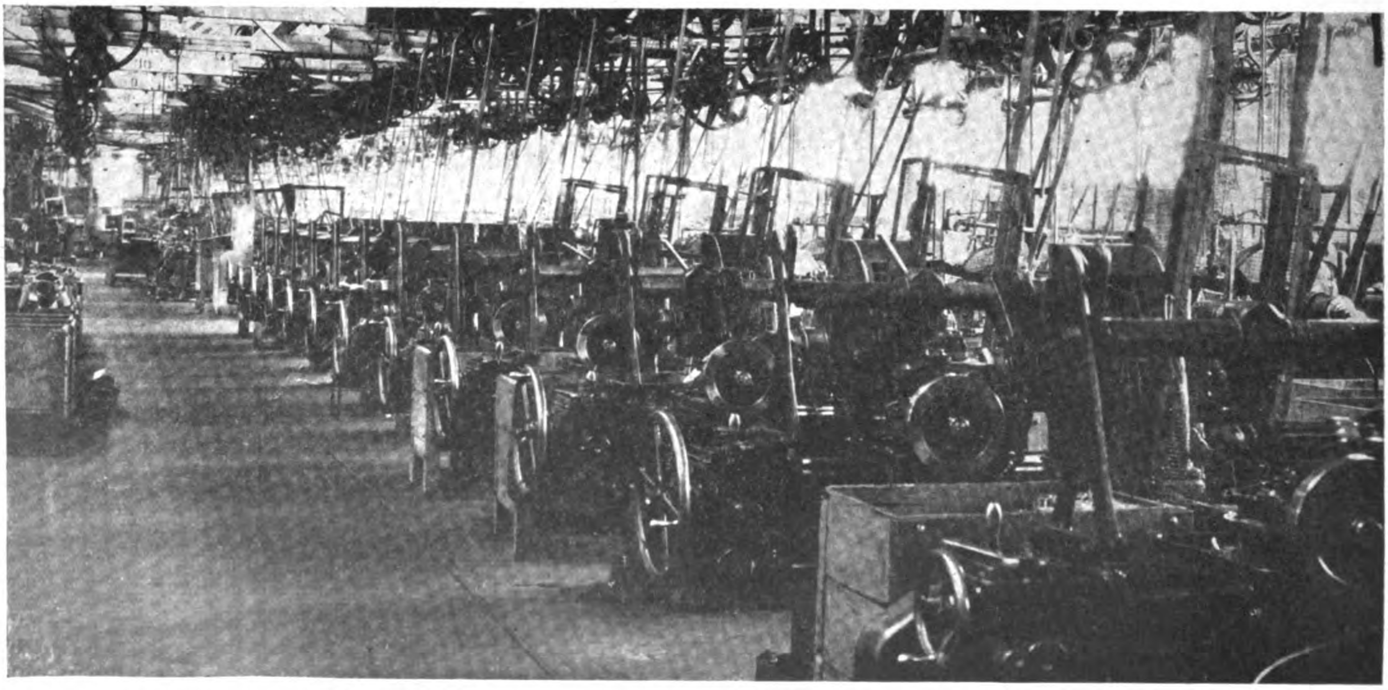
case of the automatics, one man looks after three machines.

A somewhat unusual tool for a tractor factory is a Pratt & Whitney rifle drill, which is used for drilling holes 7½ in. deep in the clutch shaft. The drill is a two-spindle machine, and drills two shafts at one time.

A uniform type of parts box is used throughout the plant, these boxes being made of 1-in. boards, which are bolted to angle-iron corner pieces, the angle iron being extended to form legs. Elevating trucks are used for carting these boxes around.

At the end of machine shop A there is a metal washing machine, in which the greasy parts, as they come from the machine tools, are cleaned in Oakite. A continuous chain conveyor operated by an electric motor draws the material through the Oakite vat. As the cleaning fluid is at a high temperature, the parts dry quickly after being removed from it.

(*To be concluded*)



Barber-Coleman gear hobbers. Note the parts boxes alongside these machines

Parcel Post Development Must Keep Up with Export Trade

EVERY person interested in export trade, whether for a large or small article of merchandise, has realized the value of an adequate parcel post service. The following article sets forth the present status of that service and indicates some of the immediate needs. It also advises that if the service does not meet with your requirements, you take up at once with the Second Assistant Postmaster General such changes as will help your business.—EDITOR.

By Allen Sinsheimer

THE rapid growth of the American export trade has served to call attention to the great advantage of an adequate parcel post service as a part of the foreign trade equipment. The quick development of the trade with the Latin-American and other countries that formerly did not buy freely from this country developed defects of the service more rapidly than they could be overcome while war conditions obtained.

Recently considerable progress has been made in overcoming these disadvantages, but trade conferences have shown that there remains a wide field for this work. In the automotive trade, the parcel post is invaluable for the shipment of small parts.

During the war many countries suspended parcel post service, but most of these have resumed, and other nations, with which the United States Post Office Department has recently negotiated, have completed parcel post conventions. A list is published herewith of the countries and the exchange post offices which dispatch and receive parcel post mails, including the countries which have resumed parcel post service interrupted by the war, those countries which have recently agreed to receive parcel post from the United States and those which have increased the weights of the parcels.

Rates Chief Obstacle to Parcel Post

The chief obstacle to extensive use of parcel post has been found in the rates and in regulations of certain nations. Maynard D. Howell, export manager of Montgomery Ward & Company, discussing this subject at the recent Foreign Trade Convention, pointed out the great advantage enjoyed by British shippers, as compared with American exporters, because of the lower rates from London as compared with those from, for example, Chicago.

Instances cited show that a 3-lb. package parcel post from London to Johannesburg costs 84 cents, a 7-lb. package $1.20 and an 11-lb. package $1.80 as compared with mail from Chicago at $1.56 for 3 lb., $3.48 for 7 lb. and $5.40 for 11 lb. Similarly, the rates to Spain, India and other countries are greatly in favor of the British shipper.

Express rates to the same points are frequently 500 per cent higher. This gives the British automotive manufacturer an important advantage. He can ship a package of spark plugs, for instance, weighing 11 lb., to Singapore for 72 cents, as compared with $5.40 from Chicago.

Furthermore, there are many of the British colonies with which the United States has no parcel post arrangement, and the only method of shipment is from the United States to England. Consequently, the automobile dealer in Nigeria, for example, can ship to this country through British parcel post, but the American manufacturer cannot ship to him except by employing an agent in London and paying postage from America to London and from London to Nigeria.

Another important obstacle is in the restrictions in certain countries, especially in Latin America, and the heavy customs duties and the complicated customs regulations in Argentina, Brazil, Cuba and other countries. Shipments to Argentina encounter a delivery fee of 30 cents, internal revenue taxes, customs duties and charges for the intervention of the customs broker, which frequently exceed the value of the contents of the parcel. Further, there are levies for storage, statistics and for return of undeliverable parcels to the point of origin.

Argentine Regulations

The parcel post administrator of Argentina insists on collecting postal charges for the return of undeliverable parcels, and, as there is no money order convention in force between the United States and Argentina, the method of payment is through postage stamps only and is cumbersome.

Venezuela charges a delivery fee equal to 30 cents for each parcel, regardless of weight, and the restriction that 44 lb. of merchandise of one sort is the most that may be imported by parcel post into Venezuela by one addressee, in the same mail, except on condition of the increase of the customs duties and other charges, causes unnecessary delays.

The chief difficulties in the Brazilian parcel post arise from the fact that the service is strictly limited to a few large cities, including Rio de Janeiro, Sao Paulo, Bello Horizonte, Bahia, Pernambuco and Para, and parcels addressed to other destinations can be delivered only when arrangements have been made by the addressee for their transmission through one of these above-mentioned post offices.

The United States Post Office can only accept parcels for delivery beyond these offices at the owner's risk. Brazilian authorities also provide that parcels must bear the amount necessary for return postage, if they are undeliverable, and the lack of a money order convention between the two countries necessitates the employment of coupons forwarded through the Post Office Department for the pre-payment of return postage.

The Bolivian parcel post was highly praised at the recent Pan-American Convention by an American ship-

per, who told of 300 parcels sent to that country, all of which had reached their destination in good condition. At the same time, there are reports from other sources that a considerable number of packages shipped to Bolivia are rifled in transit and that it is difficult to fix the responsibility for this, because the parcels are conveyed by sea to Mollendo, a Peruvian port, and require land transit through Peru.

The lack of direct communication from the Peruvian ports to eastern Peru, across the Andes, limits the service to that country. Similarly, the long transit and frequent handling of parcels to Ecuador via the Isthmus of Panama hinders successful operation of the service to that country, and this, with the fee of 24 cents for the delivery of each parcel, regardless of weight, in Ecuador, hampers the usefulness of the service.

Because of the provision in the American legislation relating to the United States and Cuba limiting shipments of cigars to parcels containing not less than 3000 cigars, Cuba feels that she would be placed at a disadvantage if she entered into a convention with the United States. Requests to Congress for a repeal of this restriction have not been complied with.

The recent conclusion of a convention with Great Britain whereby parcel post arrangements have been completed between the United States and South Africa, via the English mails, is an important step toward improvement of foreign trade relations with that country, which with Liberia forms the only section of Africa enjoying parcel post service with the United States.

Exporters favor a change in our parcel post rates so that the rate will decline with increase in weight. This is the system employed by Great Britain whereby parcel post to nearly all countries costs less per pound the heavier the package, until a minimum rate is reached. The United States has a uniform rate of 12 cents per pound, whether for 1 lb. or for 20 lb. Some of the countries with which the United States has parcel post conventions limit the parcels to 11 lb. maximum, and this has been objected to by shippers, who are requesting an increase to 22 lb.

Packing regulations in some countries, for example Italy and France, require the employment of waterproof paper for some commodities, and wooden boxes with burlap for others. These requirements are exacting and are so much more rigid than the American regulations, which merely require that every parcel must be securely and substantially packed so that it can be opened with-

Parcel Post Relations With the Following Countries Was Not Interrupted During the War. The Exchange Post Offices for These Countries Are Named:

Names of Countries	Exchange Post Offices	
*Argentina	New York, San Juan	Buenos Aires
*Australia, including Tasmania	San Francisco, Honolulu	Sydney, Melbourne, Brisbane, Adelaide, Perth, Hobart, Launceton
Bahamas	San Francisco, Honolulu	Nassau
*Barbados	San Francisco, Honolulu	Bridgetown
Bermuda	San Francisco, Honolulu	Hamilton
Bolivia	New York, San Francisco	La Paz
Brazil	New York, San Juan	Bahia, Para, Pernambuco, Rio de Janeiro, Sao Paulo
British Guiana	All offices authorized to ex	change mails between the two countries.
China	San Francisco, Seattle, Honolulu	
Colombia	All offices authorized to ex	change mails between the two countries.
Costa Rica	All offices authorized to ex	change mails between the two countries.
*Curacao (including Aruba, Bonaire, Saba, St. Eustatius and the Dutch part of St. Martins)	New York, San Juan	Willemstad
Dominican Republic	New York, San Juan	Santo Domingo
Ecuador	New York, New Orleans, San Francisco	Guayaquil
*Dutch Guiana	New York	Paramaribo
*France (excluding Algeria and Corsica)	New York	Cherbourg, Havre
*French Guiana	New York, San Juan	Cayenne
*Gibraltar	New York	Gibraltar
*Great Britain and Ireland	New York, Chicago, Boston, Philadelphia, St. Louis, Baltimore, San Francisco	London, Liverpool, Dublin
Guatemala	New York, New Orleans, San Francisco	Guatemala City, Retalhuleu, Puerto Barrios
*Guadeloupe (including Marie Galante, Deseade, Les Saints, St. Bartholomew and the French portion of St. Martins)	New York, San Juan, P. R.	Basse-Terre
Haiti	New York, San Juan	Cape Haiti, Port au Prince
Honduras (British)	New Orleans	Belize
Honduras (Republic of)	New York, New Orleans, San Francisco	Tegucigalpa, Puerto Cortez, Amapala, Trujillo
Hong-Kong. See Section 186	San Francisco, Seattle, Tacoma, Honolulu	Hong-Kong
*Italy (including Rep. of San Marino, Italian Colonies of Benadir and Erythrea, and the Italian offices at Bengazi, North Africa and Tripoli-in-Barbary and the Aegean Islands of Carpathos and Rhodes)	Philadelphia, Chicago, New York, Boston	Naples
Jamaica, including the Turks, Caicos Islands and Cayman Islands	Boston, Philadelphia, Baltimore, San Juan	Port Anton
Japan, including Formosa, Karafuto (Japanese Saghalien) and Korea. See section 186	San Francisco, Seattle, Tacoma, Honolulu	Yokohama, Kobe, Nagasaki
Leeward Islands (Antigua with Barbuda and Redonda, St. Kitts, Nevis with Anguilla, Dominica, Montserrat and the Virgin Islands, British)	New York	St. John, Antigua
*Martinique	New York, San Juan, P. R	Fort-de-France
Mexico. See section 2	All offices authorized to ex	change mails between the two countries
*Netherlands, East Indies	San Francisco	Tandjongpriok
Newfoundland	New York, Boston, Philadelphia	St. John's
New Zealand, including Fanning Island	San Francisco, Honolulu	Auckland
Nicaragua	New York, New Orleans San Francisco	Bluefields, San Juan del Norte, San Juan del Sur, Corinto
Panama. See section 2	New York, New Orleans, San Francisco	Colon, Bocas del Toro
Peru	New York, New Orleans, San Francisco	Lima
Portugal	New York	Lisbon
Salvador	New York, San Francisco	San Salvador
*Society Islands	San Francisco	Papeete
Trinidad, including Tobago	New York	Port of Spain
*Uruguay	New York, San Juan	Montevideo
Venezuela	All offices authorized to ex	change mails between the two countries.
Windward Islands (Grenada, St. Vincent, the Grenadines and St. Lucia)	All offices authorized to ex	change mails between the two countries

*Parcels cannot be registered.

out damage to its cover by postmasters and customs officials, that our shipments are frequently held up because they do not meet the foreign regulations.

The fault lies in the failure of the authorities here to negotiate conventions abroad which will recognize our methods of packing. This difficulty is also encountered in Argentina, where the American Consul General reports "because their treaty provisions are better, the parcel post service of other countries is better than ours."

The importance of extending parcel post facilities and providing for equitable service with all nations was shown recently in the instance of an automotive manufacturer who was attempting to place his literature in foreign countries. He found that the duties to the South American ports are so high that he could only ship literature in packages weighing 1 lb., as fourth class matter and not as parcel post. But custom house regulations and tax duties on these shipments caused him to give up the entire plan.

A 4-lb. package was assessed more than $5. As a result, the Department of Commerce has advised shippers that the best way to send catalogs and other literature to foreign countries is to ship them separately and obtain free admission, as single catalogs are not considered as a shipment in commercial quantities.

Catalogs and price lists sent singly are usually admitted free, excepting in South Africa, where they are free up to 8 oz. and cost 3 pence between 8 oz. and 16 oz., with an additional 1½ pence for each extra 8 oz. or fraction thereof. Advertising matter to Australia is dutiable at the rate of 10 pence per lb., or 40 per cent *ad valorem*, and the duty must be paid when the total quantity of advertising matter sent by one consignor in one mail to any one state in the commonwealth exceeds one shipping. The practice of the several countries in this regard is so varied that it is not possible to obtain a general statement which will serve as a guide, or, in fact, to obtain a complete list of the regulations of the countries of the world. Many countries have no specific provisions.

These problems are not being overlooked. The Departments of Commerce, Post Office and State are seeking to establish equitable rates and regulations, but the chief difficulties lie in the fact that in several countries, particularly in Latin America, there are no reciprocal conditions. That is, there are no inducements this country can offer for favors and no business threats which they might employ to bring about more reasonable parcel post arrangements.

The customs brokers in Argentina and Brazil are influential and have foiled every attempt to improve the regulations and, of course, reduce their fees. Furthermore, importers in some countries object to the development of parcel post service, foreseeing in it harmful competition to their own business.

In countries with which the United States now operates parcel post, parcels are allowed a maximum length of 3½ ft., length and girth combined of 6 ft., weight of 11 lb., except Ecuador, Mexico, Panama and Salvador, where the weight limit is 20 lb., and Brazil, Nicaragua, Peru, British Honduras, Columbia, Guatemala and the Republic of Honduras, where the weight is 22 lb. Parcels to China may weigh 11 lb., but must not exceed one cubic foot in volume.

The postage rate to all countries is 12 cents per pound or fraction thereof. Parcels to foreign countries cannot be sent insured or C. O. D., except to Mexico and Salvadore, where the sender of the registered parcel post package is entitled to an indemnity equal to the amount of actual loss incurred, but not exceeding 50 francs.

Parcel post relations, interrupted during the war, were resumed on the following dates:

Belgium	Jan. 27, 1919
Siam	Jan. 31, 1919
Greece	Feb. 3, 1919
Liberia	Feb. 12, 1919
Alsace and Lorraine	Feb. 20, 1919
Iceland	Feb. 21, 1919
Madeira Islands	March 11, 1919
Palestine and Mesopotamia	
Union of South Africa	April 12, 1919
Italy	April 16, 1919
Norway	April 19, 1919
Luxembourg	April 23, 1919
Paraguay	April 30, 1919
Algeria, Corsica and Tunis	April 30, 1919
Chile	May 14, 1919
Denmark, the Netherlands and Sweden	May 7, 1919
British India	May 12, 1919

It is up to the exporters to point out to the proper authorities the needs of the parcel post service to best serve the export business. While these negotiations are handled by the Departments of State, Commerce and Post Office, a letter to the Second Assistant Postmaster General will serve to notify these departments of the needs as viewed by the exporter.

Ethyl Alcohol from Waste Sulphite Liquor Using an Acclimated Yeast

RESULTS obtained from a series of investigations by the Forest Products Laboratory at Madison, Wis., upon the production of ethyl (grain) alcohol from sulphite pulp mill waste liquor are as follows:

Of the 2.0 to 2.9 per cent total sugars found in waste sulphite liquor about 55 to 62 per cent are fermentable and upon fermentation go to produce only ethyl alcohol.

Fermentations of the sulphite liquor conducted both on experimental and commercial scales showed a production of 0.7 to 1.15 per cent by volume of absolute alcohol. A plant with a capacity of 100,000 gal. of waste liquor would thus be able to produce 700 to 1150 gal. of absolute alcohol per day. Since the alcohol produced from this source contains a small quantity of methyl alcohol, but little further denaturing is necessary.

A comparison of yeasts showed that a yeast acclimated to sulphite liquor just prior to fermentation gave higher yields of alcohol than one which had been permanently acclimated to this liquor. The cost of the former process was enough greater, however, to discourage its use. This fact led the Laboratory to permanently acclimate a strain of beer yeast to this liquor and a culture was produced which gave results comparing very favorably with those obtained by the use of a freshly acclimated yeast.

A quite common custom of calculating alcohol yields from the sugar which disappears during a fermentation has been shown fallacious, since in some cases part of the sugar removed by fermentation forms substances other than alcohol.

ACCORDING to an item in an English paper a steel works is to be established at Goderich, Ontario, to manufacture motor cars and parts, trucks and tractors. It is proposed to bring ore from Michigan and to manufacture high-carbon steel. The capital of the corporation is said to be £3,000,000.

AN improved shim for babbitted bearings has been developed by the Laminated Shim Co. of New York. The shim is of the laminated type but has a babbitt edge, so that the entire bearing surface is of babbitt. The manufacturers of the shim say that undoubtedly a higher engine efficiency is obtained in this way.

Humanity and Tolerance Will Solve U. S. Labor Problems

DO you know what the recent strikes in this country mean? Have you grouped them as to cause? Do you know what steps have been taken to meet the changing conditions? Mr. Tipper has answered these questions. In this article he shows how this strike differed from that one. He shows how the radicals in labor circles have flourished through being opportunists and how they have seized, to promote their cause, strikes that were begun with an entirely different object. The following article is important to every American employer.
—EDITOR.

By Harry Tipper

IN reviewing the labor conditions and developments in the United States since the armistice, it is very important that care should be taken to distinguish between the labor unrest which has arisen out of the demands of the occupational unions affiliated with the American Federation of Labor, the unrest which has arisen out of the fight of the radical element in labor with the American Federation of Labor, the general unrest among the unskilled bodies which have been temporarily organized for some particular purpose, and the particular cases where the unrest which has occurred, through the efforts of the regularly organized unions, has been complicated by the action of the radical element after strikes had been started.

To some extent we are participating in the general spirit of unrest which follows the war as a necessary reaction from the war tension and strain. Not so much of this is due to actual strain, but a considerable part of it arises from the growth in Europe of this unrest and the suggestion which accompanies such knowledge, intelligently acted upon by the propagandists. The restrictions during the war in this country were not sufficiently severe to lead to any considerable strain and the conditions of the worker are so much better than they have been in Europe as to afford no basis of comparison in this respect.

Unemployment

The amount of unemployment is trifling in comparison with the statistics received from European countries, and the absorption of those turned out of the army and navy and from the war industries is proceeding with sufficient rapidity to indicate a lack of real surplus and a possible shortage of labor in the most important fields. There is a definite shortage of labor in a number of cities, and particularly in the automotive field.

This shortage extends into other industries where the turn-over from war production to peace necessities has not been severe and where skilled workers represent the majority of the required employees for productive purposes.

In general there is a considerable surplus of labor in various parts of the country. Although this surplus is a very small proportion of the total labor and cannot be regarded as a serious difficulty in the face of general business conditions in the United States, its position commands respect in view of world trade and the shortage of the usual immigration which has supplied a large portion of the unskilled labor in the past.

The surplus labor offers no such problem in this country as must be faced by Great Britain, and there is no reason for any alarm in respect of the totals of unemployed, particularly as from 60 to 90 per cent of those applying for jobs are placed with little difficulty.

The element of unorganized labor in this country, which is variously estimated at 5,000,000 to 7,000,000 workers, is the element which calls for the closest consideration in analyzing the question of industrial unrest. The I. W. W. organization, and similar radical bodies, claim a very large proportion of this unorganized labor as followers of their particular tenets.

There is no justification for this claim, but it is true that the I. W. W. propagandists and agitators find their greatest response from the unorganized portion of the laboring population who have no other means of voicing their grievances and have no experience with the regular machinery of the occupational union.

The total number of workers in this country who are affiliated with the American Federation of Labor is about 4,000,000 as a maximum. Before the war it was about 2,000,000. The attitude of the American Federation of Labor is conservative, and in comparison with the other organizations who are attempting to build their power on the unskilled workers, at present unorganized, their attitude is very safe and recognizes the necessity for slow development by compromise.

Labor Unrest

The reports of labor unrest in the public press as they appear from day to day make no distinction between the strikes or demands authorized by the occupational unions and those demands which have been created by the I. W. W. organization for the purpose of stimulating unrest, and those demands which have grown out of local grievances that are not recognized by the national labor leaders. The discussions in the more serious periodicals in respect of this question do not properly differentiate these various qualities of unrest and do not distinguish between the racial traditions which have some effect upon the actions taken.

With from 6 to 20 races involved in the working population of various industries, many of these races being

without any considerable knowledge of the language, the customs, the government or the political principles of the country, the possibilities of confusion in estimating the causes of industrial unrest are almost limitless.

This matter is emphasized because it has become apparent from the statements of executives of trade associations and manufacturers' bodies that the manufacturers themselves are in the dark as to the causes for much of the disturbance and are inclined to class all statements emanating from radical bodies as labor propaganda and are guilty of the mistake of confusing all unrest with the definite program of the American Federation of Labor. So long as there is no understanding of the various bodies who are engaged in promoting semi-political economic theories among the ranks of the workers of various nationalities and particularly attempting to organize those who are not organized into regular occupational unions, it will be futile to attempt to arrive at any plan which will form a basis for the solution of such difficulties.

The strikes which have occurred in this country and in Canada indicate the difference between the various demands and the difference in the origin of these strikes.

In the instance of the great sympathetic strike in Seattle, which caused such comment in this country and which was immediately defined as Bolshevism, I. W. W. and so forth, the actual history of the strike shows that it began by a demand of the workers in the government yard for an increase in pay. These workers are skilled mechanics and belong to the occupational unions. Their strike was not authorized by the unions nor approved by them but originated because of the grievance against the Emergency Fleet Corporation, which it was claimed had not kept faith with the strikers. On Feb. 7 various other union organizations went out in sympathy.

It appears from the history of this strike that the strike was originally backed by the local officials of the organized occupational unions affiliated with the American Federation of Labor, and that the control of the strike by the radical element was a later development and probably arose out of the success in bringing about sympathetic strikes and out of the prospect which was opened to the radical organization in the use of this machinery for their purpose.

The Textile Strike

The textile strike, which occurred in various centers, including Paterson, Passaic, Albany and Lawrence, Mass., was another illustration of a strike which was started by the regular occupational union and which was seized upon by the I. W. W. and other radical propagandists with the attempt to use it to their advantage and to prevent a settlement of the strike.

This strike originated with the demand of the United Textile Workers for an 8-hour day. In most parts of the country the demands were agreed to, but strikes occurred in Albany, Cohoes, Paterson, Passaic and Lawrence, Mass. In Lawrence the strike started out peacefully enough and was apparently close to a settlement when the I. W. W. and radical propagandists, who had poured into the city to foment the strike among the various nationalities, took advantage of the threatening attitude of the city officials and the mill men to organize the radical element into practical control.

This radical element succeeded in preventing a settlement of the strike for many days, by obliging the conferences to occur through them and adopting the irreconcilable attitude which is a part of their program.

The United Textile Workers branch of the American Federation of Labor not only expected a peaceful strike but withdrew its approval when the radical element succeeded in gaining control. Very few of the members who were on strike in Lawrence were members of the Textile Workers' Union, and most of them belonged to that large body of unorganized, semi-skilled and unskilled labor of various nationalities which can be swayed so easily by the promises of the more radical leaders who are interested in the extreme program of the I. W. W. This strike resulted in a general increase of wages of about 15 per cent and shortening of the hours of labor to 48 hours a week.

Another indication of the conflict which exists between the occupational unions and the I. W. W. and the importance of this conflict to the manufacturer is indicated by the copper miners' strike in Arizona, Montana and Utah. Notwithstanding the agreements of the regular occupational unions with the mine owners for conferences upon all wage questions and hours, the radical element, which claims adherence to the I. W. W., succeeded in engineering the strike and in the attempt to form a workers' government at Butte.

Other strikes which occurred on the wage question were those in the building trades, shoe trade, San Francisco shipyards, Brooklyn Rapid Transit workers, telegraphers and the expressmen and paper mill workers. Strikes which occurred in connection with hours of labor were very few, although the hours were mentioned in a good many of the strikes as a secondary and subsidiary matter.

Glass Workers' Strike

The glass workers in certain districts struck for a reduction from 12 to 8 hours. The expressmen's strike included an 8-hour day and various of the other strikes indicated that the workers were prepared to demand an 8-hour day.

One of the most important strikes which occurred in connection with the automotive field was the strike at the Willys-Overland plant in Toledo, which began on April 17 and which has not yet been settled completely. This strike assumed such great importance because it occurred in the face of the announcement of a profit sharing plan, upon which the first disbursement had just been made.

This strike was not engineered by the regular occupational unions, although a great many of the strikers were members of the unions. It was the result of the propaganda of the radicals in the labor organizations, of which Toledo has long been one of the centers of activity.

The number of alien workers in these automobile plants represents a considerable proportion of the total working population, and evidence has been accumulating for several years that it is among these alien workers the radical, semi-political, economic propagandists find their most fertile field for followers. This strike immediately took on the character of a radical socialistic movement and lost the sympathy of many of the union workers who were not in agreement with the radical program.

The strikes in Winnipeg and other sections of Canada, which are still in existence, have been advertised as Bolshevistic and I. W. W., but they are really a part of the Western Canadian unions which have been controlled by the radical element in labor circles for some years.

Many of the leaders of the Western occupational unions in Canada have come out flat-footedly in favor of one industrial union in each center, which is a part of the program of the I. W. W., and it was only by the efforts of the more conservative Eastern bodies that this program failed of adoption in the general convention of the Canadian Federated Unions.

The danger in this Canadian strike does not arise from the unorganized workers being seized by the alluring character of the radical program, but arises from the fact that the regular organizations have been controlled largely by the radical element, and this control has existed for a sufficient length of time to affect the whole policy of the local unions and their local affiliated organizations.

This disturbance, however, indicates that the idea of the industrial union and the radical program which has been a part of the policy of the Western unions in Canada has not developed such strength that it can control the whole of the labor organization. A number of unions withdrew from these strikes, and the best evidence indicates that at no time were the strikes so complete or so general as the daily reports in the newspapers would indicate.

Danger of Control by Radical Minority

At a time when there is a general unrest due to the reaction from the special strain, and also a fluidity of political opinion, there is always danger of the control of existing machinery by the radical minority temporarily, and a confusion in the minds of the outside public as to the extent of and reasons for that control.

The differences of opinion which existed in the labor ranks and the multiplicity of bodies which are attempting to deal with economic questions on the side of the worker can be illustrated in no better way than by examining the aims of labor as stated by various leaders and the resolutions adopted by various bodies. All political parties which are concerned with political propaganda under the general term of "socialism" include in their platforms economic demands, and the statements of these parties are frequently confused with the aims of occupational organizations. The general demands of occupational unions include:

1. **The 8-hour day.**
2. **The right of organization.**
3. **A tendency toward the increase of wages.**
4. **At all times an adequate wage in comparison with the cost of living.**

They also have some demands in connection with political questions, including the government ownership of public utilities and a change in the taxation methods. The various other bodies connected with labor, including the Socialist party, the I. W. W., the New York State Labor Party, fathered by the Central Federated Union of New York City, the Chicago Labor Party, and various other bodies of mixed origin, make demands running all the way from government ownership of utilities, representation in industry, 6-hour work day, the limitation of profit on invested capital, to the complete ownership of all means of production by the workers.

The American Federation of Labor to-day represents the largest general body of opinion in connection with labor conditions and similar economic questions existing among the workers in the United States. All the other bodies that claim to speak for labor and are concerned with semi-political and economic activities are so much less important, from the standpoint of their power in members and their agreement as to platform, that they should be examined and considered largely because of the value of their activities as an indication of the general tendency in certain sections of professional, semi-public and labor ranks to inject the economic developments into politics and provide a political platform of an economic character.

Any tendency for these other organizations to consolidate their aims and agree upon their demands would indicate a development of their organizations which would be of the greatest importance. So long as the number of organizations continues to multiply and the demands continue to disagree, they can be neglected for practical purposes and the situation in the labor field considered from the standpoint of the demands of the American Federation of Labor.

That these organizations become articulate and in some cases vociferous in their political propaganda, together with the evidence that most of them exist because of the complete lack of economic knowledge among a large section of the population, emphasizes the necessity for education of a better character than our present education among the workers; the importance of the right type of educators and necessity for the explanation of economic fundamentals in the curriculum.

They also emphasize the danger which exists to the industrial organizations of this country because of their neglect of all public matters, such as education, in the respective communities in which they are interested, and the important change which must take place in the business man's attitude upon all matters that he calls the politics of his community and state.

It is an unfortunate fact that most of the educators in our public secondary schools and even in our colleges have no practical working knowledge of industrial organization, its elements, its growth and its necessities, and are consequently unable to inform the students upon matters which will affect their mature lives more thoroughly than perhaps any other item.

The attitude of the employer in connection with labor questions is changing in this country, although we do not display the tolerance which is indicated by the attitude of the employers in Great Britain toward labor problems. At the same time, the developments which have occurred since the armistice was signed indicate the change which has taken place and the importance which is attached to that change by large industrial organizations. It is true that there are still a majority of manufacturers who believe the old system of organization can continue without any changes and adequately fill the bill, but many authorities in industry have indicated their vision of a change and indicated it in their utterances, not only, but in the practice in connection with their organizations.

Rockefeller's Principles

John D. Rockefeller, Jr., at the United States Chamber of Commerce Meeting, wound up a very illuminating address with a declaration of principles which is reproduced here:

1—I believe that Labor and Capital are partners, not enemies; that their interests are common interests, not opposed, and that neither can attain the fullest measure of prosperity at the expense of the other, but only in association with the other.

2—I believe that the community is an essential party to industry and that it should have adequate representation with the other parties.

3—I believe that the purpose of industry is quite as much to advance social well being as material well being and that in the pursuit of that purpose the interests of the community should be carefully considered, the well being of the employees as respects living and working conditions should be fully guarded, management should be adequately recognized and capital should be justly compensated, and that failure in any of these particulars means loss to all four.

4—I believe that every man is entitled to an oppor-

tunity to earn a living, to fair wages, to reasonable hours of work and proper working conditions; to a decent home, to the opportunity to play, to learn, to worship and to love, as well as to toil, and that the responsibility rests as heavily upon industry as upon government or society to see that these conditions and opportunities prevail.

5—I believe that industry, efficiency and initiative, wherever found, should be encouraged and adequately rewarded, and that indolence, indifference and restriction of production should be discontinued.

6—I believe that the provision of adequate means of uncovering grievances and promptly adjusting them is of fundamental importance to the successful conduct of industry.

7—I believe that the most potent measure in bringing about industrial harmony and prosperity is adequate representation of the parties in interest; that existing forms of representation should be carefully studied and availed of insofar as they may be found to have merit and are adaptable to the peculiar conditions in the various industries.

8—I believe that the most effective structure of representation is that which is built from the bottom up, which includes all employees, and, starting with the election of representatives in each industrial plant, the formation of joint works committees, of joint district councils, the annual joint conferences of all the parties in interest in a single industrial corporation, can be extended to include all plants in the same industry, all industries in a community, in a nation and in the various nations.

9—I believe that the application of right principles never fails to effect right relations; that the letter killeth and the spirit maketh alive; that forms are wholly secondary, while attitude and spirit are all important, and that only as the parties in industry are animated by the spirit of fair play, justice to all and brotherhood will any plans which they may mutually work out succeed.

10—I believe that that man renders the greatest social service who so co-operates in the organization of industry as to afford to the largest number of men the greatest opportunity for self-development and the enjoyment by every man of those benefits which his own work adds to the wealth of civilization.

This is reproduced not only because of its general declaration of principles but because the Standard Oil Co. of New Jersey, Colorado Fuel & Iron Co., Standard Oil Co. of New York, the Gilbert & Barker Co. and other companies in which Mr. Rockefeller is interested have been operating through joint councils and profit sharing developments for a year, indicating that the declaration has been capable also of a practical application in these industrial organizations.

A number of joint councils in one form or another have been adopted by the Bethlehem Steel Co., Midvale Steel Co., Lukens Steel Co., International Harvester Co., Goodyear Tire & Rubber Co., Doehler Die Casting Co., Packard Piano Co., Van Sicklen Speedometer Co. and a number of others, and this development has been growing since the armistice, so that it is unusual for a few days to pass without the record of additional business institutions who are operating under this system in one of its various forms.

Notwithstanding these facts, there is a considerable body of opinion among the manufacturers who believe that the old method of warfare between the union and the employer must go on and are not prepared to make any concessions or to consider any changes in organization. This is indicated by the suggestions made at the National Association of Manufacturers at its convention:

1—Fair dealing as the fundamental and basic principle.

2—No opposition to labor organizations — but against illegal acts of interference with the personal liberty of other employees (the open shop).

3—No discrimination regarding employment because of membership in labor organizations, but also no discrimination by employees against fellow employees who are not members of labor organizations (the open shop).

4—Right of employee to leave his employment whenever he sees fit, and equal right of the employer to discharge.

5—Freedom to adjust wages between employer and employee without interference or dictation on the part of individuals or organizations outside of the industrial enterprise concerned.

6—Freedom of employees against molestation or interference in their business and in the methods they choose to adopt or systems of pay, provided same are just and equitable.

7—No limitation upon opportunities for any person to learn any trade. (Restrictions as to apprenticeship.)

8—No strikes and lockouts, but amicable adjustment through methods that will preserve the rights of both parties.

9—Acknowledgment of the right of employees to contract for services through collective bargaining, but repudiation of stipulations that employment should be denied to men not parties to such contracts. (In other words, this is a declaration against the closed shop.)

10—A pledge of National Association of Manufacturers to oppose any and all legislation not in accord with the foregoing declarations.

However, when leaders like Frank Shove, president of the National Association of Cotton Manufacturers; Frank A. Vanderlip, banker; John N. Willys, president of the Willys-Overland Co.; Eugene M. Grace, president of the Bethlehem Steel Corp., and many more who can be quoted, admit that the worker should have some say in the government of his own conditions of work and that there should be tolerance and amicable possibilities of adjustment, the situation has developed sufficiently to merit the hope that the United States can offer a basis for the solution of its problem, which will be more advantageous in its permanent effects than the solutions which must be considered by the European countries where the conditions are entirely different.

There has been a general desire in this country to keep the labor question out of the political arena, a desire which is voiced by the president of the American Federation of Labor just as definitely as it is voiced by the manufacturer. The war made it necessary for the government to interfere in the labor situation to a considerable degree, and there is evidence that economic questions will inevitably become political questions by the very necessity for industrial peace and the recognition of the widespread demand for change in conditions.

Interference of government in the conduct of industry in respect of the hours, wages and working conditions is always to be deprecated unless the impossibility of decent agreement makes it necessary from the public standpoint. For many years the government in this country has been obliged to formulate regulations limiting the number of hours which can be worked in certain industries because of the character of these industries or

the character of the labor. It has been obliged to regulate on questions of employers' liability and similar matters, on questions of factory space per man, lighting, sanitation and other matters which concern the public health.

The Government and Industry

In its general regulation of industry from the workers' standpoint, the government, in this country, has done less than any other country. There is no general sentiment as yet for the limitation of child labor and there are many states in which there is no such regulation at this time. The sanitary regulations vary from state to state and the public necessities have not yet forced any general agreement upon the fundamental living conditions in connection with industrial work.

The difficulty of government action in connection with industrial necessity arises from the fact that standard regulation imposes as much hardship as it prevents. Taking no account of the local conditions involved, of the particular character of the work, and of the particular character of the individual organization, it cannot modify its regulations to take advantage or correct these local differences.

For this reason the smallest amount of government regulation consistent with the public welfare is the best position industrially. Notwithstanding these facts, there is a persistent demand for government action in connection with industrial matters—a demand frequently favored by the public, which has become tired of being subjected to the inconveniences arising out of the continual warfare between employers and employees and their almost total neglect of the public necessities when their own demands are at stake.

Political action upon labor matters and their economic necessities is being demanded more than ever, and the government at Washington is more sensitive to the labor development than at any other time.

Regulation of Troubles

All through the political body, with its preponderance of lawyers, there exists the idea that regulation is the general panacea for all troubles, and just as soon as we get a few bomb outrages we must immediately enact a sheaf of new laws, even though the old ones are perfectly good if they were properly enforced and operated. The number of new laws put into effect in each State reach a surprising total when they are collected, and the constant demand for regulations of this kind indicates that a large body of public opinion believes that regulation is the best way to bring about the result.

Under these circumstances it is obvious that the amount of regulation that will be put into effect depends largely upon the attitude of the manufacturer. If he will divest himself from the idea that he has *no obligation to the public*, if he will throw away his prejudices and analyze the conditions, he will appreciate that, whether he agrees with the situation or not, the tendency of the times *demands that he discuss the workers' problems with them*, that he accede to the right of the public to criticize and investigate his method of doing business and that the law of supply and demand is not a principle governing the human beings, and that the health of the body politic is more important to that body than the success of his individual enterprise.

Inasmuch as the worker, either brain or hand worker, constitutes a large majority of the voting population and his opinions and ideas are astonishingly different from those of the majority of manufacturers, it is not difficult to conceive of the present tendency toward governmental regulation continuing and enlarging its scope, unless the manufacturers realize that political power can be used to secure industrial power, just as industrial power was used in the past to secure political power.

There is no escape in Great Britain from the political decision upon labor matters because the issue has been drawn for so long, and the warfare continued so intensively, that one of the largest political bodies has been created for the purpose of enforcing economic demands, and it is not unlikely that the labor party in Great Britain may be called upon to supply the cabinet for the British Empire at the next election. There is a possibility in this country of providing a basis for the solution of the labor problem without bringing it squarely into the political arena and making the solution more difficult by that fact.

The first steps toward this solution have been taken. There is a better understanding between labor and capital, or rather between employer and employee. There is a better disposition on both sides and practical men have devised practical means of providing machinery for the solution of many of these questions. A continuance of the tendency in this direction will open up the possibility of the settlement of these matters without the necessity for a great deal of governmental intervention, and a settlement of them along what would seem to be a most orderly line. The unrest is not serious, the radical element is not unduly large, but the demand for a better understanding is widespread and the recognition that industrial organization as it was has not fulfilled its obligations to society is equally widespread. A review of the six months gives hope that industry is cognizant of the situation and operating to meet it.

Swedox Rod and Wire Filler for Welding

COINCIDENT with the development of the newer welding processes, there has been great improvement and specialization in the materials used. The Central Steel & Wire Co. of Chicago is manufacturing eight varieties of "filler," each adapted for a particular kind of ferrous metal.

Only seven years ago comparatively little autogenous welding was being done, and the attention of the officials of the Central Steel & Wire Co. was first directed to the subject when a manufacturer of steel barrels became one of their steady customers, buying an unusual amount of welding wire. The metallurgists of the company were instructed to investigate the subject of welding as a whole.

As a result of their preliminary investigation, they proposed the adoption of the present form of rods and wires. This was an important step, but what is regarded as a vastly more important step was the adoption of special treatments of welding wires for electric welding and acetylene welding, respectively.

As the investigation was carried farther, it was found that better results could be obtained by using slightly different fillers for different grades of steel to be welded. This development finally led to the adoption of eight distinct fillers which are now being offered by the company. These eight fillers are as follows:

Mannox, for acetylene welding; Lektrox, for electric welding; Castox, for cast iron; Carbox, for cast steel; Vanox, for vanadium metal; Nickox, for nickel welding; Kromox, for chrome nickel, and Railox, for use in welding railroad tracks, switches, rods, etc. All are known by the family name of Swedox.

Air Weight and Volume Measurement

PART II

Theory of the Venturi Meter as Applied to Liquids and as Applied to Gases

By Don T. Hastings

THE theory of the venturi meter is based on natural laws whose accuracy has been many times proven by the most competent investigators. Careful tests also of well-made venturi meters have repeatedly shown results well within 1 per cent of the theoretical.

Theory for Liquids

The theory of the venturi meter used to measure liquids is as follows: Liquids are practically incompressible; consequently, if the flow through the venturi meter is steady, equal volumes of the liquid must pass through all sections of the meter in a given length of time. The volume passing any section per second is equal to the area of the section multiplied by the velocity of flow. Expressing this in symbols, let

A = area in square feet of large section venturi
a = area in square feet of throat
Q = volume in cubic feet passing any section per second
V = velocity in feet per second through large section of venturi
v = velocity in feet per second through throat

Then $Q = AV = av$.

The quantities V and v are related according to the formula

$$\frac{V^2}{2g} + \frac{P}{W} + H = \frac{v^2}{2g} + \frac{p}{W}$$

in which friction in the meter is neglected and

g = acceleration of gravity = 32.16 ft. per sec. per sec.
P = absolute pressure in the pipe in pounds per sq. in. at large section
p = absolute pressure at throat
W = weight of liquid per cubic foot in pounds
H = distance of large section of meter above (or below) throat in feet

When the axis of the meter is horizontal, as is usually the case, $H = O$ and

$$\frac{V^2}{2g}\ \frac{W}{P} - \frac{V^2}{2g} + \frac{p}{W}$$

The formulae (2) and (3) are based fundamentally on the principle of the conservation of energy. The quantity $\frac{V^2}{2\,g}$ is the so-called "velocity head" and represents the height required to produce the velocity v of a body starting from rest under the influence of the acceleration of gravity g. $\frac{P}{W}$ is the "pressure head" and represents the height of a column of the liquid required to produce the pressure exerted on the liquid. It is thus seen that all the quantities in formulae (2) and (3) represent heights or "heads." The derivation of the formula can be found in any standard reference work on Hydraulics if desired.

From (1)

$$V^2 = v^2 \times \frac{a^2}{A^2}$$

and substituting in (3)

and transposing

$$\frac{v^2}{2\,g} - \left(\frac{v^2}{2\,g} \times \frac{a^2}{A^2}\right) = \frac{P}{W} - \frac{p}{W} \qquad (4)$$

$$\frac{v^2}{2\,g}\left(1 - \frac{a^2}{A^2}\right) = \frac{P - p}{W} \qquad (5)$$

$$v^2 = \frac{2\,g}{\left(1 - \frac{a^2}{A^2}\right)} \times \frac{P - p}{W} = \frac{1}{1 - \frac{a^2}{A^2}} \times 2\,g \times \frac{P - p}{W} \qquad (6)$$

$$v = \sqrt{\frac{1}{1 - \left(\frac{a^2}{A}\right)}} \times \sqrt{2\,g\,\frac{P - p}{W}} \qquad (7)$$

Substituting the value of v as computed from equation (7) in equation (1) gives the quantity.

Theory for Gases

The formulae derived above for liquids flowing through a venturi meter are applicable to gases, because gases are compressible and consequently the density of the gas varies with changes in pressure and temperature. The result is that equal *volumes* do not pass the various sections of the venturi in the same length of time. If the flow is steady, however, equal *weights* of the gas must pass all sections in equal time intervals and on this basis formulae may be derived. In the following, friction losses will be disregarded, as they have been proven entirely negligible; the discussion also is limited to venturi tubes whose axes are horizontal, thus eliminating the factor due to the difference in height or the "static head." In practice it is always possible and usually by far most convenient to set the venturi tubes in this position.

Departing for a moment from the venturi meter, consider a piston moving in a cylinder as a result of the pressure exerted on it by the gas filling the cylinder. Assume that this pressure is maintained constant as the piston moves. The work done on the piston, neglecting friction and temperature effects, is measured by the force exerted, multiplied by the distance the piston is moved, or

Work = Force × Distance
Force = Gas Pressure × Area of Piston
and Work = Pressure × Area × Distance

The area multiplied by the distance equals the volume displaced by the gas during the time the work was done, so the expression may be written

Work = Pressure × Volume
or $W = P \times V$

If the pressure does not remain uniform but varies during the movement, as is usually the case, the same formula can be applied by subdividing the distance into as many parts as may be necessary, so that the pressure during any one part of the travel is practically constant, multiplying the pressure during each part of the travel by its corresponding small volume and adding the results together, as

$$W = P_1V_1 + P_2V_2 + P_3V_3 + \ldots\ldots\ldots + P_nV_n$$

This expression shows that the work done is the sum of such terms as $P\ V$; when V is made very small to get accurate results it is usually written "dV." The formula is then written

$$W = \int_{V_1}^{V_2} P\, dV$$

In words this means that W is equal to the sum of such terms as $P\ dV$ between the limits V_1 and V_2, V_1 and V_2 being the volumes at the beginning and end of the working period.

This formula can be evaluated graphically for any particular case, as, for example, that of a steam engine indicator diagram. Whent here is a known algebraic relation between the various pressures and their corresponding volumes, the solution can be found mathematically.

Consider now a straight tube of uniform diameter through which gas is flowing steadily. Imagine that the gas is divided into discs or layers at right angles to the axis of the pipe. Each disc will press on the layer in front of it and in turn be pressed on by the layer behind it. Any disc or layer may then be compared to the piston in its cylinder, with reference to the gas immediately behind it.

If the diameter of the pipe is not uniform, but contracted, as in a venturi tube, the analogy still holds, though in this case the pressure and volume are both changing. The formula still holds, however, and we may write as the fundamental equation of the venturi tube

$$W = \int_{V_1}^{V_2} P\, dV \tag{9}$$

The next step is to determine the algebraic relation between P and V so that the formula can be put into usable shape.

Countless experiments by numerous scientists have proven that for all gases, including air, this relation is given by the general formula

$$P V^s = P_1 V_1^s = P_2 V_2^s = K$$

in which
$P\ P_1\ P_2$ = absolute pressures
$V\ V_1\ V_2$ = volumes
s = an exponent usually greater than 1 and less than 1.5
K = a constant

The values of s and K have been most carefully determined for air and many other gases under various conditions, and may be found in any standard work on Thermo-Dynamics. The particular values for use in the case of air measurement by means of the venturi meter will be given later.

From equation (9)

$$P = \frac{K}{V^s} \tag{10}$$

Substituting in equation (8)

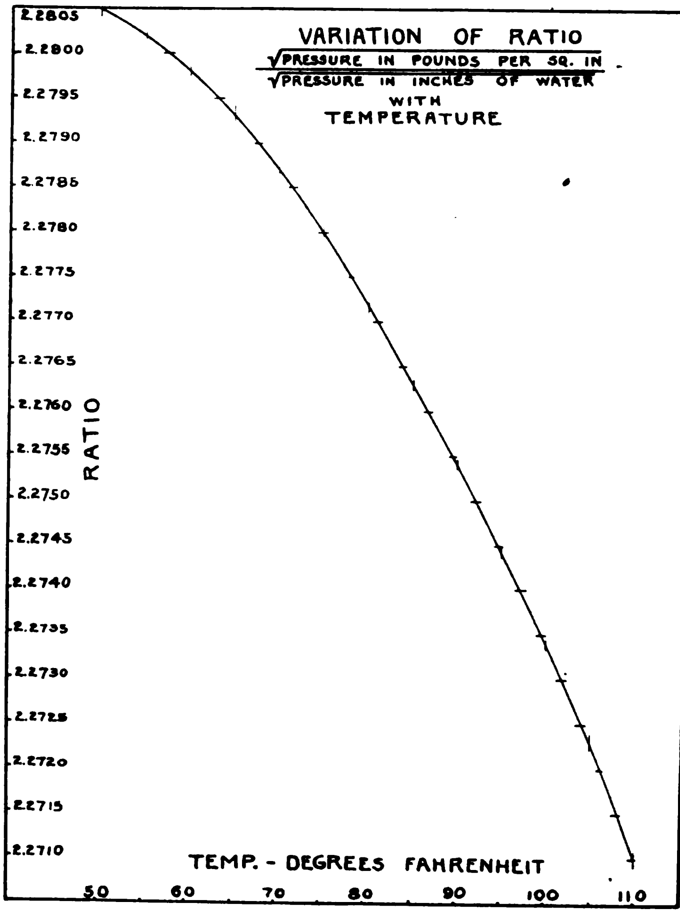

Fig. 11

$$W = \int_{V_1}^{V_2} \frac{K}{V^s}\, dV \tag{11}$$

As K is a constant it may be moved outside the summation sign, and we get

$$W = K \int_{V_1}^{V_2} \frac{dV}{V^s} \tag{12}$$

The mathematical process of integration is now applied and we get

$$W = K \int_{V_1}^{V_2} \frac{dV}{V^s} = K \int_{V_1}^{V_2} V^{-s} dV$$

$$= \frac{K}{1-s}\left[V_2^{1-s} - V_1^{1-s}\right] \tag{13}$$

As s is greater than 1 as stated above the denominator and both exponents are negative; changing form to get positive values, we have

$$W = \frac{K}{s-1}\left[\frac{1}{V_1^{s-1}} - \frac{1}{V_2^{s-1}}\right] \tag{14}$$

To get the equation in more convenient form multiply and divide by the factor $\frac{1}{V_2^{s-1}}$ or $\frac{1}{V_1^{s-1}}$

$$W = \frac{K}{s-1} \times \frac{1}{V_2^{s-1}}\left[\frac{V_2^{s-1}}{V_1^{s-1}} - 1\right] \tag{15a}$$

$$\text{or } W = \frac{K}{s-1} \times \frac{1}{V_1^{s-1}}\left[1 - \frac{V_1^{s-1}}{V_2^{s-1}}\right] \tag{15b}$$

Substituting the values of K from (9) we get

$$W = \frac{1}{s-1} \times \frac{P_2 V_2^s}{V_2^{s-1}}\left[\left(\frac{V_2}{V_1}\right)^{s-1} - 1\right] \quad (16a)$$

$$W = \frac{1}{s-1} \times \frac{P_1 V_1^s}{V_1^{s-1}}\left[1 - \left(\frac{V_1}{V_2}\right)^{s-1}\right] \quad (16b)$$

Cancelling

$$W = \frac{P_2 V_2}{s-1}\left[\left(\frac{V_2}{V_1}\right)^{s-1} - 1\right] \quad (17a)$$

$$W = \frac{P_1 V_1}{s-1}\left[1 - \left(\frac{V_1}{V_2}\right)^{s-1}\right] \quad (17b)$$

Again from equation (9) we get

$$\frac{P_2}{P_1} = \left(\frac{V_1}{V_2}\right)^s \quad \text{and} \quad \frac{P_1}{P_2} = \left(\frac{V_2}{V_1}\right)^s \quad (18)$$

Extracting the S root we get

$$\frac{P_2}{P_1}^{\frac{1}{s}} = \frac{V_1}{V_2} \quad \text{and} \quad \left(\frac{P_1}{P_2}\right)^{\frac{1}{s}} = \frac{V_2}{V_1} \quad (19)$$

Raising to the $s - 1$ power

$$\left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}} = \left(\frac{V_1}{V_2}\right)^{s-1} \quad \text{and} \quad \left(\frac{P_1}{P_2}\right)^{\frac{s-1}{s}} = \left(\frac{V_2}{V_1}\right)^{s-1} \quad (20)$$

Substituting these values in (17a) and (17b)

$$W = \frac{P_2 V_2}{s-1}\left[\left(\frac{P_1}{P_2}\right)^{\frac{s-1}{s}} - 1\right] \quad (21a)$$

$$W = \frac{P_1 V_1}{s-1}\left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] \quad (21b)$$

Either of these equations (21a) and (21b) represents the work done during the expansion of the gas, that is, during its change from the P_1, V_1 condition to the P_2, V_2 condition. To get the total work done, however, we must add to this expression the work done at the constant initial pressure in replacing the gas which has been expanded and must subtract the work done at the constant final pressure in displacing the volume of gas necessary to permit the flow to take place. This gives us, using only equation (21b) for convenience

$$W = P_1 V_1 + \frac{P_1 V_1}{s-1}\left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] - P_2 V_2 \quad (22)$$

Referring again to (9) we may write

$$P_1 V_1 V_1^{s-1} = P_2 V_2 V_2^{s-1} \quad (23)$$

and

$$P_2 V_2 = P_1 V_1 \left(\frac{V_1}{V_2}\right)^{s-1} \quad (24)$$

Substituting from (20)

$$P_2 V_2 = P_1 V_1 \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}} \quad (25)$$

Substituting in (22)

$$W = P_1 V_1 + \frac{P_1 V_1}{s-1}\left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] - P_1 V_1 \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}} \quad (26)$$

$$W = P_1 V_1\left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] + \frac{P_1 V_1}{s-1}\left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] \quad (27)$$

$$W = P_1 V_1\left[1 + \frac{1}{s-1}\right]\left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] \quad (28)$$

$$W = \frac{s}{s-1} P_1 V_1 \left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] \quad (29)$$

Equation (29) represents the total work done on the gas during its change of condition; it consequently is equal to the difference in energy possessed by the gas before and after the change. The initial energy is given by the expression

$$E_1 = \tfrac{1}{2} m u_1^2$$

and the final energy by

$$E_2 = \tfrac{1}{2} m u_2^2$$

m = the mass of the gas
u_1 = velocity at large upstream section of the venturi tube
u_2 = velocity at throat of venturi

Subtracting,

$$W = E_2 - E_1 = \tfrac{1}{2} m (u_2^2 - u_1^2) \quad (30)$$

Substitute for m its equivalent $\frac{w}{g}$

w being the weight of the gas in pounds and g being the acceleration due to gravity = 32.159 ft. per second.[2]

$$W = \frac{w}{2g}(u_2^2 - u_1^2) \quad (31)$$

If w is taken as 1 pound and u_1 and u_2 are measured in feet per second, we may combine equations (29) and (31)

$$W = \frac{1}{2g}(u_2^2 - u_1^2) = \frac{s}{s-1} P_1 V_1 \left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] \quad (32)$$

Since we have taken W = 1 pound V_1 becomes the volume of 1 pound of the gas at the pressure P_1 and consequently $\frac{1}{V_1}$ = the density d_1 at that pressure, from which,

$$V_1 = \frac{1}{d_1} \quad (33)$$

Substituting in (32) we have

$$u_2^2 - u_1^2 = 2g \frac{s}{s-1} \frac{P_1}{d_1}\left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] \quad (34)$$

As equal weights pass both upstream and throat sections in equal time intervals, the velocities, densities and areas must be related as follows:

$$w = w_1 = w_2 = A_1 u_1 d_1 = A_2 u_2 d_2 \quad (35)$$

But

$$\frac{d_2}{d_1} = \frac{V_1}{V_2} \quad \text{from (33)}$$

and

$$\frac{V_1}{V_2} = \left(\frac{P_2}{P_1}\right)^{\frac{1}{s}} \quad \text{from (19)}$$

$$\text{so} \quad d_2 = d_1 \left(\frac{P_2}{P_1}\right)^{\frac{1}{s}} \quad (36)$$

Substituting in (35) and dividing out d_1,

$$u_1 = \frac{A_2}{A_1} u_2 \left(\frac{P_2}{P_1}\right)^{\frac{1}{s}} \quad (37)$$

Squaring this value of u_1 and substituting in equation (34)

$$u_2^2 - \left(\frac{A_2}{A_1}\right)^2 u_2^2 \left(\frac{P_2}{P_1}\right)^{\frac{2}{s}} =$$

$$2g\,\frac{s}{s-1}\,\frac{P_1}{d_1}\left[1-\left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] \qquad (38)$$

$$u_2^2\left[1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{\frac{2}{s}}\right]=$$

$$2g\,\frac{s}{s-1}\,\frac{P_1}{d_1}\left[1-\left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}\right] \qquad (39)$$

$$u_2 = \sqrt{2g\,\frac{s}{s-1}\,\frac{P_1}{d_1}\left[\frac{1-\left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}}{1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{\frac{2}{s}}}\right]} \qquad (40)$$

Substituting this value of u_2 and the value of d_2 from (36) in (35)

$$w\left(\begin{matrix}\text{pounds}\\ \text{per second}\end{matrix}\right) =$$

$$A_2 d_1\left(\frac{P_2}{P_1}\right)^{\frac{1}{s}}\sqrt{2g\,\frac{s}{s-1}\,\frac{P_1}{d_1}\left[\frac{1-\left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}}{1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{\frac{2}{s}}}\right]}$$

from which

$$w = A_2\left(\frac{P_2}{P_1}\right)^{\frac{1}{s}}\sqrt{2g\,\frac{s}{s-1}\,P_1\,d_1\left[\frac{1-\left(\frac{P_2}{P_1}\right)^{\frac{s-1}{s}}}{1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{\frac{2}{s}}}\right]} \qquad (41)$$

In this formula the various quantities must be measured in the proper units; they are consequently recapitulated below for convenience:

- w = weight of air flowing in pounds per second
- A_2 = area of throat of Venturi tube in square feet
- P_1 = pressure in upstream part of Venturi tube in pounds per square foot absolute.
- P_2 = pressure in throat in pounds per square foot absolute
- g = acceleration of gravity = 32.159 ft. per second^2
- s = an exponent whose value in this case is 1.4028—this is the value which has been determined for air when its expansion is adiabatic; that is, when no heat is given up by the air to the walls of its containing vessel nor any received by the air from the walls. This is assumed to be the case in flow through Venturi tubes due to the high velocities employed and seems to be justified, as many extremely careful tests have been made to check the instrument with results of errors of less than 1 per cent in all cases
- d_1 = density in pounds per cubic foot of air in upstream section of Venturi tube—the determination of this factor will be discussed later
- A_1 = area of upstream section of Venturi tube in square feet

Substitution of the numerical values of g and s simplifies formula (41) somewhat

$$w = A_2\left(\frac{P_2}{P_1}\right)^{0.71286}\sqrt{64.318\times 3.48262\;P_1\,d_1} \times\sqrt{\frac{1-\left(\frac{P_2}{P_1}\right)^{0.28714}}{1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{1.42573}}} \qquad (42)$$

Extracting the numerical root and squaring $\left(\frac{P_2}{P_1}\right)^{0.71286}$ in order to place it under the radical sign

$$w = 14.96647\;A_2\sqrt{P_1}\sqrt{d_1}\;\sqrt{\times\frac{\left(\frac{P_2}{P_1}\right)^{1.42572}\left[1-\left(\frac{P_2}{P_1}\right)^{0.28714}\right]}{\left[1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{1.42572}\right]}} \qquad (43)$$

It will be more convenient to read the weight as pounds per minute instead of per second, so we multiply by 60. It is also desirable to express the area in square inches instead of square feet, so we divide by 144.

$$w\ (\text{lb. p. m.}) = 6.23603\,A_2\ (\text{sq. in.})\ \sqrt{P_1}\sqrt{d_1}\sqrt{\text{—}} \qquad (44)$$

For convenience in reading pressures, water manometers will be used. The readings of a water manometer will vary with the temperature; at 78 deg. F. a 1-in. column of water represents a pressure per square foot of 5.1875 lb. At 50 deg. F. this value is 5.2075 lb., and at 110 deg. F. 5.1575 lb. As we are concerned only with the square roots of these quantities, we get the following relations:

At 50 deg. F., 2.2805
At 78 deg. F., 2.2776
At 110 deg. F., 2.2710

The values of this conversion factor are shown in Fig. 11; between the limits given, which are the extremes usually met in practice, the variation either way from the value corresponding to 78 deg. F. is less than 0.3 per cent. This variation may be taken into account when extreme accuracy is desired, but for all ordinary purposes we may use the factor 2.2776. The temperature of 78 deg. F. is chosen as this is about the average temperature encountered in ordinary work.

Introducing this factor (by multiplication) and reading P_1, in inches of water absolute, the formula becomes

$$w = 14.203\;A_2\sqrt{P_1}\sqrt{d_1}\;\frac{\sqrt{\left(\frac{P_2}{P_1}\right)^{1.42572}\times\left[1-\left(\frac{P_2}{P_1}\right)^{.28714}\right]}}{\sqrt{1-\left(\frac{A_2}{A_1}\right)^2\left(\frac{P_2}{P_1}\right)^{1.42572}}} \qquad (45)$$

in which

- w = pounds per minute
- A_2 = area in square inches of throat
- P_1 = pressure in inches of water absolute
- d_1 = density in pounds per cubic foot of dry air at pressure P_1
- $\frac{P_2}{P_1}$ = ratio of absolute pressures at throat and upstream. This ratio must be kept between the limits .950 and .995 to secure the best results.
- $\frac{A_2}{A_1}$ = ratio of *areas* of throat and upstream section. This ratio should be ¼ to 1/16.

The FORVM

Status of Lorraine-Dietrich Aircraft Engine When Examined by U. S. Engineers

By M. Barbarou

AS a member of the Society of Automotive Engineers and Technical Director of the Lorraine-Dietrich Co. (Route de Bezons, Argenteuil, France), I take the liberty of drawing your attention to a paragraph of an article by J. G. Vincent headed "Lorraine-Dietrich Held Up as a Model," which appeared in your magazine dated February 6. This article contains inaccuracies, and I shall feel much obliged if you will kindly correct same. I wish to most emphatically contradict the statement that the "Lorraine-Dietrich" eight-cylinder motor was in the "experimental state" when the officers delegated by the United States Government came to examine it.

I am glad to learn that the engineers who came to examine the Lorraine engine were Captain Clark and Capt. Howard Marmon, for they never introduced themselves to any of the managers of the firm, which latter had given instructions that all persons delegated by the United States Government should have free access to all parts of the works.

These officers came to see the Lorraine-Dietrich Co. in July and August, 1917, and this type of engine, perfectly tuned up for quantity production, underwent a successful official test of 50 hr. Dec. 26-30, 1916, as you will see by the detailed test performance I am enclosing herewith, certified correct by the inspection officer of the Lorraine-Dietrich Works. The details of this engine were quite settled for manufacturing in series.

I must add that the Lorraine-Dietrich Co. made a series of high altitude tests (Lautaret pass) with this engine, beginning July 30, 1917. I consider that it is stretching the truth when the author says in the article that the Lorraine-Dietrich engine was in the "experimental state" and that this applied more to the Liberty engine.

The Lorraine-Dietrich Co. received numerous calls from different United States officers for the supply of inlet manifolds and carbureter parts to improve the carburetion of the engine. I proposed to tune up the engine (carburetion, etc.).

I am sending you in this connection photographs and a translation of a letter sent by the French War Office to the Lorraine-Dietrich Co. on July 6, 1918, and a confirmation of a telephonic message sent by the French Technical Section for Aviation on June 19, 1918. You will notice from these documents that the Lorraine-Dietrich Co. offered the United States Government a free manufacturing license for its aviation engines.

With regard to the 370-hp. twelve-cylinder engine, the Lorraine-Dietrich Co. was asked for a sample engine toward the end of 1918, and I refused to have it delivered, not seeing the necessity of supplying a model in view of the manufacture of the Liberty engine.

I shall feel obliged if you will kindly publish this letter in your magazine, so that your readers may know that when the United States Government sent a delegation of engineers to France to study the Lorraine motors, this company had several types which were absolutely ready, from every point of view, for quantity production.—M. BARBAROU, *Technical Director, Lorraine-Dietrich Co.*

Letter of the Director of Military Aviation (France) to the Administrator of the Lorraine-Dietrich Co.

(Translation)

DEAR SIR: I have the honor to inform you that the Aircraft Manufacturing Department has received the necessary instructions to deliver to your works as soon as possible, in agreement with the Aviation Technical Department, a Liberty engine, in order that your specialists may try to improve its carburetion.

In your letter of June 17, you also offered to the French Government, for the American Aviation, a free manufacturing license for your 500 hp. and 1000 hp. motors.

I beg to express my best thanks for this suggestion, as also for the first one, and wish to congratulate you for having so thoroughly and with so broad minded a spirit understood the role of collaboration which firms such as yours cannot fail to play with regard to our American allies.

I am advising of your offer General Patrick, Director of the American Aviation Expeditionary Force, 45 Avenue Montaigne.

Yours faithfully,

(Signed) PAUL DHE, Director of Military Aviation.

Confirmation of Telephone Message No. 3284/Mo. D Sent June 19, 1918, at 17.50 o'clock

(Translation)

COMMANDER CAQUOT.

Director of Aviation Technical Section to the Under-Secretary of State for Aeronautics.

TUNING UP OF LIBERTY MOTOR

In agreement with the Lorraine-Dietrich Co., which is willing to help us, I suggest that you should deliver to the Lorraine works the Liberty motor now at Chalais, in order to improve the carburetion. I am advising the American Aviation.

(Signed) CAQUOT.

—

An Appreciation

Editor AUTOMOTIVE INDUSTRIES:

I want to thank you for the space given in the current issue of AUTOMOTIVE INDUSTRIES to the Class B rules for tractor tests adopted by the American Society of Agricultural Engineers, and also for the editorial comment on these rules.

This publicity co-operation will be greatly appreciated by all the members of the American Society of Agricultural Engineers.

Thanking you for the courtesy, we are,

Yours very truly,

(Signed) RAYMOND OLNEY,

President American Society of Agricultural Engineers.

St. Joseph, Mo., June 10, 1919.

—

Berling Magneto on Bender Special

WE are informed of a mistake in the table in AUTOMOTIVE INDUSTRIES in which the equipment of the cars in the Indianapolis Speedway race was described. The table specified the Bosch magneto as a part of the equipment of the Bender Special. It appears that two weeks before the race this car was equipped with two Berling type 5-41 magnetos. This was the first use of Berlings in racing and reports to the company are that the operation was faultless.

—

Air Measurement—Errata

A NUMBER of typographical errors occurred in the article on Air Weight and Volume Measurement by Don T. Hastings in our June 12 issue, as follows:

P. 1282—col. 2—line 13—second t should be $t_1 = 71$ deg. Fahr.

P. 1282—col. 2—line 17—P should be P_1 and d should be d_1.

P. 1282—col. 2—line 22—$\frac{A_2}{A_1} = 0.200$ instead of 200.

P. 1287—col. 1—line 6 should read

$$b - e + 0.622e = b - 0.378e$$

the minus sign having been omitted.

—

THE annual meeting of the International Aeronautic Federation will be held in Brussels, the date to be fixed. Next year's meeting will be in Geneva. Aero Clubs of Japan and Brazil have been admitted.

Details of the Still Hydrocarbon-Steam Engine

British Product, Which Uses in Main Cylinder Any Form of Liquid or Gaseous Fuel Hitherto Employed, Ranked Above Diesel in Announcement

A GREAT deal of interest has developed in England in a new design of engine announced by W. J. Still, which he claims is more efficient than the Diesel engine. From a correspondent we learn that Mr. Still spent about half a million dollars in experimental work before announcing his engine. Following are some particulars of the Still engine taken from a paper read before the Royal Society of Arts by Frank D. Acland.

The Still engine is an engine capable of using in its main working cylinder any form of liquid or gaseous fuel hitherto employed; it makes use of the recoverable heat which passes through the surfaces of the combustion cylinder, as well as into the exhaust gases, for the evaporation of steam, which steam is expanded in the combustion cylinder itself on one side of the main piston, the combustion stroke acting on the other side. It increases the power of the engine and reduces the consumption of the fuel per horsepower developed.

Its primary object is not to use the waste heat for raising steam, but first to use it in improving the thermal conditions of the working cylinder, and so insure the maximum efficiency from the fuel burnt within it, diminishing, as a consequence, the heat lost in that operation. Since the maximum efficiency is obtained by combustion of the fuel in the cylinder, and the minimum by the evaporation of the water in the steam generator, it is evident that the larger the quantity of steam which can be generated per horsepower developed by the combustion cycle, the lower must be the heat efficiency of the whole machine.

In the Still engine—see diagram—the jacket and cooling water form part of the circulating system of a steam generator, which may be an integral part of the engine, or external to it. The cooling water therefore enters and leaves the jacket at a constant temperature, regulated by the pressure of the steam, the cooling being effected by converting the water into steam without raising its temperature. Excluding the radiation losses, which are kept low by lagging, all the heat which passes through the walls is thus usefully recovered in the water as steam. The temperature of the cylinder wall is uniform over the whole of its exterior surface, and the heat lost to the cooling water at each stage of the cycle—compression, combustion and expansion—is diminished.

During compression, owing to the walls being at steam temperature, the incoming charge picks up heat instead of losing it during the greater part of the stroke, an advantage of the greatest value to the heavy oil types of Still engines, where an air charge is taken in at the full out-stroke, and is compressed to a pressure where its increased temperature insures the certain ignition and combustion of the fuel which is injected into it.

During combustion and expansion the uniform and higher mean temperature of the walls reduces the heat lost to the jacket water. Some of the heat thus economized adds to the useful work on the piston, the balance passing out in the exhaust gases for recovery.

The cylinder of a Still engine consists of an inner liner, which is approximately one-third to one-fourth of the usual thickness; it is ribbed externally so as to add to its conducting surface and provide suitable passage for the cooling water, and it is reinforced by an outer hoop capable of withstanding the highest pressures to be met with in working. No failure of a cylinder of any kind has occurred, even under most severe, even abnormal test conditions, *e.g.*, with mean combustion pressures of 180 lb. per square inch in a two-stroke engine, to which was added overload steam mean pressures of 70 lb., *i.e.*, a total mean effective pressure per revolution of 250 lb. per square inch.

The Still engine may be of the constant volume or constant pressure type, or a combination of both; its losses to the cooling water are not the same as in a normal engine of either type, except in so far that they vary with the type, with the cycle, with the efficiency of the com-

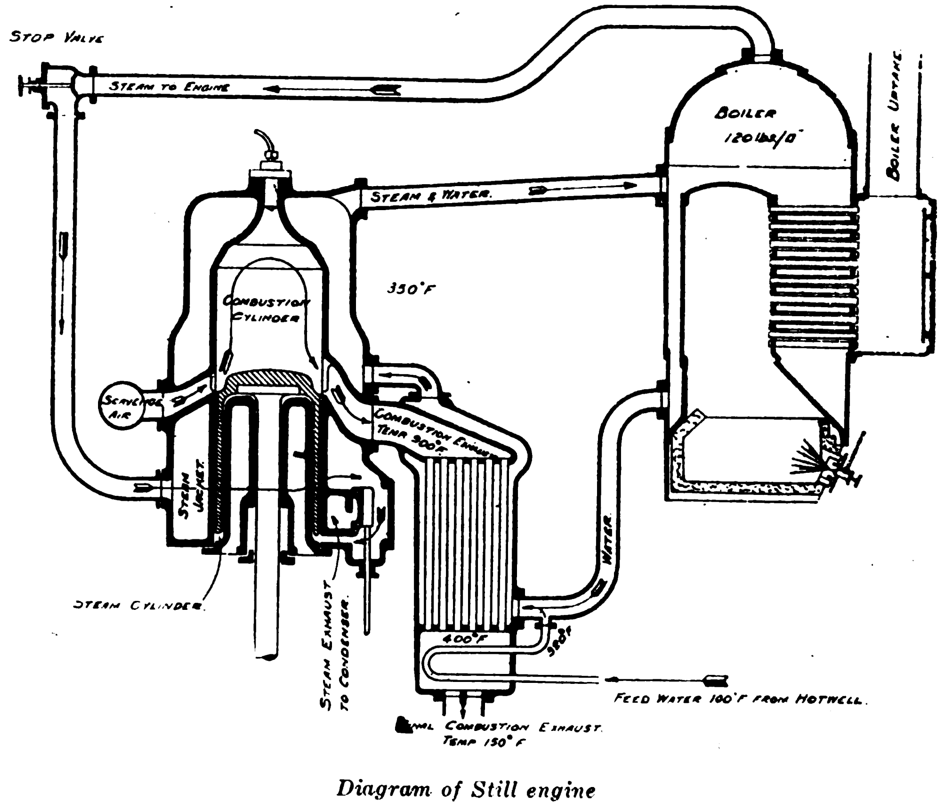

Diagram of Still engine

bustion stroke, and with the load. At normal and full loads, such heat units, in a Still engine, as pass into the jacket water, which is at steam temperature and pressure, are lessened and are wholly recovered without loss—radiation excluded—in overcoming the latent heat of the water and give off their steam in the steam space in proportion to the heat flow at those loads. At lower loads less steam is produced, until at still lower loads no steam at all is measurable. In other words, the jacket losses are practically eliminated.

Exhaust Gases

The exhaust gases take a subsidiary, but important, part in the cycle; their usefulness in ordinary combustion engines, in raising steam, is limited to the amount of heat recoverable between the initial temperature of the exhaust and that of, say, 50 deg. Fahr. above the steam temperature, after which the whole volume passes away to atmosphere at a still useful temperature, less a small percentage available for feed-water heating. But in the Still engine the exhaust gases, after raising their quantum of steam, are employed in preheating all the water required for the steam generated in the jacket water and in the generator. Trials at full efficiency over long periods and steady loads show terminal stack temperatures as low as 150 deg. Fahr. The heat efficiency of the combined cycles is therefore exceedingly good, with an initial temperature of over 2000 deg. Fahr. and a final exhaust to atmosphere at 150 deg. Fahr.

The quantity of steam capable of being generated from "waste heat" depends upon the efficiency of the combustion cycle, and on the load. Some years of experimental work prove that the weight of steam recovered may vary from a maximum of about 7 lb. per brake horsepower hour developed by the combustion cycle of a four-stroke constant volume engine at full load to a minimum at light loads which is hardly measurable, and which only balances the loss due to radiation.

The engine used for this research was of constant volume type, four-stroke. It first underwent a series of tests, so as to arrive at its "initial horsepower" as an explosion engine, *i.e.*, without any power added by the steam cycle, and was carefully checked in this connection by comparison with well-known and authenticated trials carried out by the late Prof. Bertram Hopkinson, F.R.S., and others. Though it was a single-cylinder unit with automatic inlet valves, its "initial horsepower" was rated on a par with the power given by four-cylinder sets with mechanically operated valves deduced from tests made over very short periods and under their best conditions.

The quantity of steam generated per "initial brake horsepower" from the jacket alone averaged 3.28 lb. per brake horsepower-hour, and from the jacket and exhaust together 6 lb. per brake horsepower-hour, this being the average of the whole of the trials over periods varying from 20 minutes to over six hours. The final six hours of a 7½ hours' continued test gave a total recovery of 6.9 lb. of steam per initial brake horsepower.

Normal load.—The average mean effective pressure from the combustion stroke was 90 lb. per square inch. The steam evaporated by the "waste heat" gave 14 lb. per square inch mean effective pressure on every return stroke. This is equivalent to $90 + 28 = 118$ lb. per square inch mean effective pressure in a normal four-stroke engine.

Overload.—By admitting additional steam generated by fuel under the boiler, the steam mean effective pressure was raised to 72 lb. per square inch; the total mean effective pressure was therefore equal to $90 + 144 = 234$ lb. per square inch mean effective pressure in a normal four-stroke engine.

The Still engine was first shown at the Aero-Marine Show held in London in April, 1914. Since that exhibition much of development work has been done on the engine.

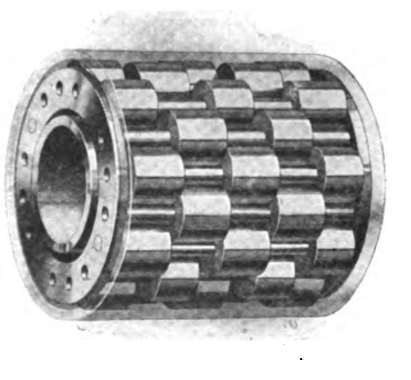
The Hart Roller Bearing

A NEW type of roller bearing with several staggered rows of rollers has been developed by the Hart Roller Bearing Co., East Orange, N. J. In the opinion of the designer of this bearing the great angular distance between adjacent rollers in an ordinary roller bearing with a single row of rollers is the cause of considerable strain on the bearing. This difficulty is overcome in the Hart bearing. Other improvements in the Hart construction are intended to promote the circulation of lubricant, to reduce the friction between the rollers and the cage, and to eliminate tilting of rollers due to variations in the position of the load on them.

In the Hart bearing the rollers are staggered, and two different widths of rollers are used, arranged with the staggered end in assembly and meshed, so that the entire surfaces of the shaft and the outer casing are covered. The rollers are mounted on alignment shafts supported at the end by retainer rings, in which they revolve freely.

The staggered arrangement of the rollers results in a reduction of the angular distance between adjacent lines of contact, which is claimed to reduce the strain to which the bearing rings are subjected. It also provides space for free circulation of oil or grease.

The Hart bearing can be arranged for operation in either a horizontal or a vertical plane, without any tendency to dragging due to frictional resistance between the rollers and cage, it is claimed. The end of any roller which is lightly loaded is free to rotate independently of the heavily loaded end. The result is a differential movement between individual sctions of a given roller, and the objectionable features of eccentric loading are thus overcome.



Hart roller bearings

It is claimed that the distinctive feature of the Hart roller bearing — its staggered and meshed roller arrangement—gives the bearing a greater load capacity than that of other bearings. The rollers are made of chrome-vanadium steel, and are carefully heat-treated. All parts of the bearing are accurately machined and ground. These bearings are designed for both light and heavy duty purposes, where radial bearing loads have to be supported. They are suited for use on trucks, farm tractors, jackshafts, marine shafts, line shafts, etc.

WRAPPING cross-grained struts with cotton tape according to standard methods has no appreciable effect on their strength. It is doubtful if any other methods of wrapping, such as cording, would increase the strength properties very greatly. There is also the probability that any wrapping or covering will be loosened by weather changes.

It is believed that canvas, tape or cord covering is of less value than the same volume of wood.

Farm Tractor Design

PART II

A Practical Example of Calculations Preceding the Design of a Tractor—Data Useful to the Tractor Engineer

By Joseph Jandasek, M. E., E. E.

IN plowing one acre of land the tractor travels a definite number of miles, depending on the number of bottoms and the width of each, as follows:

Plows	One 8-in.	One 10-in.	One 12-in.	One 14-in.
Miles	12.2	9.9	8.2	7
Plows	One 16-in.	Two 14-in.	Three 14-in.	
Miles	3.5	3.5	2.33	

A tractor pulling two 14-in. plows at a speed of 3½ m.p.h. plows just as much as a machine pulling three 14-in. plows at a speed of 2.33 m.p.h., viz., one acre per hour.

Acreage Per Mile Travel with Various Plowing Widths in Feet

Width	1	4	5	6	8	10
Acres	0.121	0.484	0.605	0.726	0.968	1.211

A strip 1 ft. wide and 43,560 ft. or 8.25 miles long equals one acre. A strip 99 in. wide and 1 mile long equals 43,560 sq. ft. or one acre.

What a two-plow tractor can accomplish in 8 hours' work at 2½ m.p.h. (no time being allowed for stops, though, of course, this amounts to a great percentage in some cases) is given herewith:

Plowing, two 14-in. plows.................. 5.5 acres
Discing, 16-disk, 8 ft. wide disk harrow......20 acres
Harrowing, 3-section harrow, 5 ft. wide each..35 acres
Drilling, one 12 x 8—8-ft. drill..............20 acres
Harvesting corn, one corn binder............ 9.5 acres
Harvesting grain, one 8-ft. grain binder......20 acres
Mowing, two 5-ft. mowers...................24 acres
Hay loading, one 8-ft. rake loader and picks up a 20-ton load ....13 acres
Planting corn, two planters, 40-in. rows......32 acres
42-in. rows......33.5 acres
44-in. rows......35 acres
Cultivating corn, one double-row cultivator,
40-in. rows ....16 acres
42-in. rows ....16.8 acres
44-in. rows ....17.6 acres

Table I—Speeds and Drawbar Pulls

Miles per Hour	Feet per Minute	Pull in Lbs. per 1 H.P.
1	88	375
1¾	154	214
2	176	187
2¼	198	166
2½	220	150
2¾	242	136
3	264	125
3¼	286	115
3½	308	107
3¾	330	100
4	352	93
4½	396	83
5	440	75
5½	484	69
6	528	63
7	617	53
8	705	47

Table II—Wheel Diameters, Speeds of Revolution and Miles Per Hour

Miles per Hour	Wheel Diameter in Inches					
	36	42	48	52	54	56
1	9.3	8	7.0	6.4	6.2	6.0
2	18.7	16	14.0	13.0	12.4	12.0
2¼	21.0	18	15.7	14.5	14.0	13.5
2½	23.4	20	17.5	16.2	15.5	15.0
2¾	25.7	22	19.2	17.7	17.0	16.5
3	28.0	24	21.0	19.5	18.6	18.0
3¼	30.4	26	22.7	21.0	20.2	19.5
3½	32.7	28	24.5	22.5	21.7	21.0

2¾	4.4	6.6	7.7	11.5
3	4.8	7.2	8.4	12.7
3½	5.6	8.5	9.8	14.8

Practical Calculations

The following are taken as requirements: We have to build a tractor capable of pulling three 14-in. plows, climbing a gradient up to 10 per cent in soils with ground resistance up to 15 per cent, equipped with two driving wheels in the rear and two front wheels for steering, with three speeds forward and one reverse, a low speed of 2 m.p.h., a plowing speed of 3 m.p.h. and a high speed of 8 m.p.h.

SOLUTION: Since one 14-in. plow requires a pull of 1000 lb., the drawbar pull at plowing speed must be..............................3000 lb.
and the rated pull at plowing speed, $0.80 \times 3000 =$ ....2400 lb.
Since weight = pull at plowing speed, the total weight should be about.....................3000 lb.
The actual weight, however, will probably run a little higher, about.........................3300 lb.

We also have:

Drawbar pull at low speed, equation

(2) $P_l = 1.5W = 4500$ lb.

Ground resistance (3) $t = 0.15$ (for stubble plowing)

grade resistance (5) $g = 0.10$

total rolling resistance $= (t + g)W = 750$ lb.

Drawbar horsepowers

(6) $\text{D.H.P.} = \dfrac{P_r}{375} S_p = 24$ hp. (not considered slippage)

(7) $$\text{B.H.P.} = \frac{P_p + (t+g)W}{375E_t} S_p = 35.3 \text{ hp.}$$

assuming $E_t = 0.84$.

Engine dimensions:

(27) $B = 0.765\sqrt{\text{B.H.P.}}$ (for 4-cylinder 4-cycle gasoline engines, 80 lb. mean effective brake pressure and 900 ft. per min. piston speed) $B = 4.55$ in.

$$L = 1.3B = 5.9 \text{ in.}$$

practically: $4\frac{1}{2} \times 6$

(11) $$N = 6\frac{W_p}{L} = \frac{6 \times 900}{6} = 900 \text{ r.p.m.}$$

Piston displacement: $c = \pi B^2 L$ (for 4 cyl.) $= 382$ cu. in.

$$\text{Checking: B.H.P.} = \frac{B^2LN}{12{,}600}4 = 35 \text{ hp.}$$

$$\text{Torque} = \frac{B^2L_p}{4} = 2420 \text{ in.-lb.}$$

Beltwork (one gearset between engine and pulley) using equation (14):

$$\text{Belt H.P.} = 0.95 \times 35 = 33.2 \text{ hp.}$$

Size of grain separator, 26 in.

Size of pulley:

(15) $$d = \frac{10{,}000}{n_p} (n_p = N = 900) d = 11 \text{ in.}$$

face, $8\frac{1}{2}$ in.

Selecting 48-in. diameter of driving wheels as smallest practical we have

(32) $$n = \frac{S}{D} \quad 336$$

and gear ratio at plowing speed

(30) $$G = \frac{N}{n}, \text{ we obtain:}$$

at 2 m.p.h.....$n = 14$ r.p.m., $g = 64.3$
at 3 m.p.h.....$n = 21$ r.p.m., $g = 42.8$
at 8 m.p.h.....$n = 56$ r.p.m., $g = 16.1$

Checking the pull and drawbar horsepowers:

(38) $$P = \frac{E_tG}{D} \times \frac{Cp}{2\pi} - (t+g)W$$

$$P_p = 2930 \text{ lb.}$$

(40) $$\text{D.H.P.} = \frac{NC4}{\pi 12{,}600} E_t - (t+g)W\frac{S_p}{375} = 23.5 \text{ hp.}$$

$$\text{Efficiency} = \frac{23.5}{35} = 0.67$$

Face of driving wheels,

(43) $$F = \frac{W}{34\sqrt{D}} = 12.4 \text{ in., we will take 12 in.}$$

Selecting a 36-in. diameter for the front wheels (largest possible), we have

(46) $$f = \frac{W}{100\sqrt{D_f}} = 4.9, \text{ we will take 5 in.}$$

Road work, for available pull on road we have

(55) $$P_r = \tfrac{2}{3} W = 2000 \text{ lb.}$$

and for weight which can be hauled on grades up to 10 per cent,

(58) $$W_h = 5P_s = 10{,}000 \text{ lb.}$$

Weight distribution: according to formula (71) $a = 1.5 (6 + 12) + 24 \times 0.25 = a = 33$ in.

(73) Wheelbase $H = 2.5\,a = H = 82$ in.

(74) Tread $A = 2.25\,c = A = 54$ in.

c equals about to R_d.

Weight on front at standstill, using the formula (60):

$$W_f = W\frac{a}{H} = 1210 \text{ lb., or 40 per cent.}$$

$$W_d = 1790 \text{ lb., or 60 per cent.}$$

Weight distribution on level under the following conditions: $P = 1500$ lb. (500 lb. per plow), $h = 17$ in.:

$$a' = \frac{1500}{3000}17 + 24 \times 0.15 = 12.1 \text{ in.}$$

$$a = a' = 33 - 12.1 = 20.9 \text{ in.}$$

$$W'_f = 3000\frac{20.9}{82} = 765 \text{ lb.}$$

$$W'_d = 2235 \text{ lb.}$$

Weight efficiency in this case 74.5 per cent. Weight on front required for side draft,

$$a_s = 1.5 \times 6 = 9 \text{ in.}$$

$$W_s = 3000\frac{9}{82} = 330 \text{ lb.}$$

At what pull will tractor tip over (not considering shocks, inertia of the machine and of the flywheel) when (a) $h = 12$ in., (b) $h = 17$ in.?

(a) $$33 = \frac{P}{3000}12 + 24 \times 0.25$$

$$P = 6750 \text{ lb.}$$

(b) $$33 = \frac{P}{3000}17 + 24 \times 0.25$$

$$P = 4750 \text{ lb.}$$

From the above we can see how important it is to have the drawbar hitch comparatively low when plowing at low speed. Otherwise, there is danger that the tractor will tip over.

Table IV—Calculated Data of Different Size Tractors

Calculated in the same way as the foregoing practical example, with the following assumptions: All engines of the 4-cylinder 4-cycle gasoline type: $P_e = W$; $p = 80$ lb.; $V_p = 900$ ft. p. m.; $t + g = 0.25$ lb.; $E_t = 0.84$; $E_b = 0.95$; $n_p = N$; $i = 17$ lb.; $d = 1$ in.

HORSELESS AGE SUBSCRIBERS
Subscriptions for the Horseless Age transferred to the subscription list of AUTOMOTIVE INDUSTRIES in the merging of the two publications will be completed in full by the weekly issues of AUTOMOTIVE INDUSTRIES to the dates of expiration shown on the records of the Horseless Age Co.

Owned by United Publishers Corporation, Address 239 West 39th St., New York; H. M. Swetland, President; Charles G. Phillips, Vice-President; W. H. Taylor, Treasurer; A. C. Pearson, Secretary.
Entered as second-class matter Jan. 2, 1903, at the post-office at New York, New York, under the Act of March 3, 1879.
Member of the Audit Bureau of Circulations.
Automotive Industries—The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Let Us Have Free Discussions

THE annual summer meeting of the Society of Automotive Engineers will soon be under way. Ottawa Beach will be the Mecca of hundreds of engineers in this industry. Others allied with the industry in such a way as to make their experience invaluable will also be present.

A number of important papers are going to be presented for discussion at this meeting. Let them be discussed freely. If there has been any criticism of S. A. E. meetings in the past, it has been that there has been inadequate discussion. Papers have been read and while many have been eager to discuss them, the time was so limited that this was not possible.

This year a more open program has been adopted with the result that there will be more time for discussion. Let the members use it to advantage in bringing out the full meaning and value of these papers.

The Non-Stop Trans-Ocean Flight

ANOTHER milestone in the history of mechanical flight was passed last Sunday when the two British aviators Alcock and Brown succeeded in crossing the Atlantic Ocean in an airplane without an intermediate landing. It was a fine mechanical performance and a fine piece of sportsmanship. Alcock and Brown took long chances. Luck was with them and they won. They are entitled to all the credit which naturally is due to the first crew successfully to cross the ocean in a single stage.

From the details of the flight, the machines, etc., published elsewhere in this issue, it is apparent that Alcock surrounded himself with more safeguards than did Hawker, and this no doubt was one of the reasons for his success. In the first place, Alcock had two engines instead of a single one and therefore did not have all his eggs in one basket, as it were, though according to all accounts both of his engines ran perfectly throughout the trip. Secondly, he seems to have had a materially greater fuel reserve, which would have been a great help had wind and weather been at all unfavorable. As it turned out, the wind throughout the trip seems to have been very favorable, since the maximum speed claimed for the Vickers is only a little over 100 m. p. h. and the plan was to throttle the machine to 90 m. p. h. for the sake of reducing strains and minimizing the fuel consumption. Actually an average speed of 121 m. p. h. was maintained, which shows an average favorable wind of over 30 m. p. h. for the whole trip, if the intention of flying at 90 m. p. h. relative to the air was adhered to.

Mention of the favorable conditions is not made here to detract from the achievement of the intrepid aviators. In fact, the good weather conditions under which the trip was achieved bear testimony to their perspicuity, for it is one of the problems of a transatlantic flight to start when the weather promises to be favorable for the approximate length of time required for the trip.

The great flight has been achieved and will be recorded in history as a memorable event. It is reported that some of the other contestants who are still waiting in Newfoundland for a chance to start the trip will try to better Alcock's time. But with the *Daily Mail* prize won and the ocean once crossed in the air, much of the incentive for the hazardous trip has been eliminated. An improvement on Alcock's time is not only going to be a very difficult task but would mean very little in the way of furthering commercial aviation. What would be of great importance in this connection would be a reduction of the chances of non-success or the presentation of convincing proof that these chances are small when the proper precautions are taken. A succession of flights might have both these desirable results and the aircraft industries of the world may consider the lessons to be learned and the propaganda to be achieved worth the cost of renewed attempts.

Super-Induction in Commercial Engines

IN the past, engine development has been along the lines of greater flexibility, more silent operation and increased power in proportion to weight or displacement volume. In all of these respects the automobile engine has attained a very high standard. Little attention has yet been given to the problem of improving the fuel economy of the engine and it is obvious that under present conditions fuel economy is a very important characteristic. While the achievements in engine design in regard to flexibility, silence and high weight efficiency are highly valued, it may be necessary in the future to sacrifice some of the progress made along these lines in order to increase the fuel economy or make possible the use of cheaper fuels than the present motor gasoline. At any rate, any new design of engine will be judged very largely on the basis of its fuel economy.

It is for this reason that not much can be expected from super-induction engines in which the working cylinder is filled with charge to a pressure above atmospheric. Such an engine may be justified for war plane service where cost is a negligible factor and maximum speed counts for everything. But it is not a commercial possibility in an age where fuel conservation is one of the great needs.

A gasoline engine of the conventional four stroke type receiving more than a normal charge of explosive mixture works under substantially the same conditions as a steam engine with late cut-off. Both will develop abnormal power at the expense of economy. The chief reason for the decreased economy in the gasoline engine is that at the end of the stroke, since there is a great deal more burnt gas in the cylinder, the pressure of the gases—that is, the exhaust pressure—is much higher, and much more energy is thrown away in the exhaust. It is a fundamental principle of heat engines that the efficiency depends upon the initial and final temperatures of the expanding charge, and if the final temperature of the charge is raised the efficiency is lowered. A higher exhaust pressure means a higher final temperature.

If the fuel situation becomes sufficiently acute we may even see engines built with sub-normal induction so as to gain the advantage of expansion practically down to atmospheric pressure. This could be done by closing the inlet valves before the end of the inlet stroke. The compression space would, of course, have to be reduced so as to obtain full compression with a partial charge, as the compression has a strong influence on the efficiency. In a conventional four stroke engine the exhaust pressure under full load is about 50 lb. per square inch gage, and by farther expanding the gas considerable additional energy can be recovered. But this end is attained at the expense of some loss in the maximum output from an engine of given size.

Develop Foreign Parcel Post

AN extensive foreign parcel post system equal in rates and privileges with those of other nations is invaluable in the development of American export trade. The parcel post is the battery of foreign business. It carries the spark of interest in catalogs and other trade literature. It lights the way to big export trade and works constantly after big trade is started, connecting the importer and exporter when small parts and supplies are needed.

The service must be equal to that enjoyed by our competitors. So long as American manufacturers must pay higher rates and meet unreasonable regulations abroad, our parcel post, like the battery, is undercharged and useless. American shippers can not compete for trade in India so long as British makers can ship an 11-pound package to Calcutta for 72 cents, while the American pays $5.40. They can not sell in Brazil or Argentina when the customs brokers' fees and delivery charges are in excess of the worth of the parcel. They might as well try to start with a dead battery as to compete with such handicaps.

Frequently exporters encounter difficulties in the parcel post abroad which our authorities are unaware of until they are brought to their attention. Exporters encountering such difficulties will find the postal authorities keenly appreciative of specific examples of wrongs that may be righted. Foreign parcel post problems sent to the Second Assistant Postmaster General will meet with prompt attention.

Good Roads Duties

IT is up to everyone in any way connected with the automotive industry to stand behind the good roads movement which is sweeping throughout the country in order that it may be kept moving in the right direction.

The development of roads within the next few years is vital to this industry. Every mile of new road built through the rural districts creates prospects for trucks, automobiles and tractor sales.

Parts manufacturers are just as much interested in the good roads movement as the vehicle manufacturers. Just because a manufacturer is making jacks, spark plugs, wrenches, or axles is no reason why he should let the passenger car, truck or tractor manufacturer do the work.

Millions have been appropriated by various states for road construction this year. The big task now is to see that these millions are expended in a way to encourage future activities. An active interest should be maintained by those interested in watching the expenditure of the money. Do not let these funds become side tracked or misused, but concentrate them in such a way as to get the most and best roads for the money expended.

By united action, the endorsement for good roads can be made so strong that no one could afford to ignore it, and bear in mind that the manufacturer of multiple spindle drills, artificial leather, porcelain and any other line of wares in just as vitally interested as the automobile manufacturer.

Latest News of the

Overland Factory Is Back in Production

4,000 Return to Work—Plant Under Government Protection—Returned Workers Not Molested

TOLEDO, OHIO, June 17—All departments of the Willys-Overland plant are running to-day for the first time since June 3, when rioting caused the company to suspend operations. Approximately 4000 men are back at work. No cars are being turned out, and it may be 2 weeks before the first machines are completed. In some of the departments almost full crews are on the job, while in others work is being carried on by skeleton organizations.

The plant is operating under the protection of the United States District Court and is guarded by 270 special deputy marshals, as well as hundreds of factory guards, soldiers and policemen. The plant opened last Thursday and there has been no violence, although several arrests have been made for contempt of court. The union has pickets on all gates. They pass out cards stating their case and asking those who pass them not to enter, but there is no disorder.

Clarence A. Earl, vice-president and general manager of the Willys-Overland plant, said that petitions will be filed before Judge Killets in the District Court to-morrow, asking the court to make the injunction under which the factory is now operating permanent. This injunction limits picketing and gives the company full government protection.

Earl's Statement

Vice-president Earl said to-day: "Our plant is now in operation in all departments. We are getting under way as rapidly as possible for an increase to full production. The time for talk is over. It is time the company and its employees got back to work.

"The number of men who came to work Monday was greater than we expected. With continued excellent protection there is no reason why any man who wants to work should stay at home. We have extended a cordial welcome to all desirable employees, and we wish to reiterate that all such employees are welcome and are invited to return.

"But, in order that no worker may be misled, it is important that every employee understand clearly that we shall be obliged, in order to maintain balanced production and carry out our program, to fill with other workers the places of those who do not return promptly.

"Men who think for themselves have known from the start that the company's position has been not only fair, but extremely liberal. This strike has been one of the most unfair impositions ever imposed upon a group of fair-minded workmen. It has from the beginning been clearly a case of the radical minority intimidating the majority. We have now, and have had from the beginning, unbounded faith in the loyalty of the large majority of our employees, and we sympathize with those who have been misled."

—

AERIAL NAVIGATION IN BRAZIL

WASHINGTON, June 13—The Handley-Page Co., London, England, has secured concessions to operate airplanes in Brazil. The concession is for ten years but does not give exclusive monopolies on privileges. It further provides that within two years the Government may demand that the pilots be Brazilian citizens, and that the machines must be registered with the Inspector of Navigation.

The Handley-Page Co. will inaugurate an aerial line between Buenos Aires and Pernambuco and will use machines of 3000 hp. and capable of transporting 7700 lb. at an average speed of 112 kilometers per hour. It is expected that the voyage between Buenos Aires and Pernambuco will be made in three days with stops at Porto Alegre and Rio de Janeiro. The planes will travel by day only and the passengers will stop at night in hotels to be operated by the company. It is expected the service will start within six months. The airships will have a capacity for 12 passengers, with baggage, and one ton of freight.

—

RAINIER FOREIGN CONNECTIONS

FLUSHING N. Y., June 13—The export department of the Rainier Motor Corp. will be represented in Australia and New Zealand by the New York Oversea Co., New York City; in Norway by Haller, Kopsland & Co., Christiania, and in Greece by the Youroveta Home & Foreign Trade Co., New York City.

—

25,000 DODGES BEHIND ORDERS

DETROIT, June 16—Dodge Brothers are 25,000 cars behind orders. Production is between 450 and 500 cars daily. There are several trucks in use in Detroit with Dodge chassis. The company denies that it has any intention of going into the truck manufacturing business, although there has been a rumor to that effect here.

French Accuse A. E. F. of Destroying Vehicles

Burn Army Material to Procure Scrap for Sale According to Government Contract

PARIS, June 18 (*Special Cable*)—A violent storm of protest has been raging in the French press around the allegation that the American army is burning complete cars and destroying motorcycles and tanks at Romorantin, because of the refusal of the French Government to allow these vehicles to be disposed of in France.

The truth of the matter is that the American army automobile organizations are now cleaning up with a view of quick return to America. Under the agreement with the French Government, the Army is permitted to sell scrap material but must not allow complete vehicles to get on the market.

Many of the cars in stock have been through the war and are in such condition that they are not worth shipping home. The bodies of these cars are, of course, composed of wood and metal, and to release the metal so that it can be sold as scrap, the bodies have been burned. To have separated the metal by other means would have been a waste of labor. Partially wrecked motorcycles and tanks were included in this burning.

Later is was found that the French junk dealers had recovered entire frames from this scrap and were putting these on the market as such. This was regarded as a violation of the order that only scrap should be sold. To meet this condition, an order has been given that a Holt caterpillar tractor shall be run over these fire ruins before the scrap is sold.

French newspapers have obtained pictures of this tractor breaking up the scrap motorcycles and are using them as proof that the American army is wilfully destroying good vehicles.

—

FORDSON REDUCED $135

DETROIT, June 16—Henry Ford & Son is wiring all distributers of a reduction of $135 in the price of the Fordson tractor. The new price, effective at once, is $750. The old price was $885. The price to the distributer is $600 and he turns it over to the dealer at $635.

The Fordson tractor plant is now getting back into heavy production. Approximately 100 machines are being completed daily. A carrier system similar to the one in the Ford Motor Co. plant at Highland park is being installed.

Automotive Industries

Sale of British War Vehicles Begins

High Prices Are Paid for 300 Motorcycles at Auction—Trucks Next

LONDON, ENGLAND, June 3—The first of the Government sales of war vehicles has been held in the Royal Agricultural Hall, Islington, and 300 motorcycles were disposed of at amazing prices. The entire sale was by auction. Thirty thousand trucks and hundreds of cycles will be sold in a series of auctions.

Many of the cycles offered at this sale were in bad condition. The first lots offered had been in service, and in many cases handle bars and wheels were missing and often cylinders were gone.

Solo cycles that were more like scrap than vehicles brought an average price of $150. Damaged cycles with side cars attached brought $210 to $350.

Douglas motorcycles, still in crates and unused, ranged in price from $383 to $650. These cycles have twin horizontal opposed cylinder engines.

The Board of Trade has announced an additional ruling for the import of American cars. This is in behalf of the importers not established in 1913, and who have no basis of apportionment under existing regulations. These firms are to be permitted cars to a number to be agreed upon by all members of the Automobile Section of the American Chamber of Commerce. Licenses will be in force until Sept. 1, when revision will be made.

AIRCRAFT TOOLS FOR SALE

WASHINGTON, June 14—Aircraft production machine tools valued at $11,000,000 are available for sale by the War Department. Terms and time of sale have not yet been announced. It is expected that some of these tools will be sold in Europe.

NO CARS TO ARMY OFFICERS

WASHINGTON, June 16—No passenger cars will be sold by the War Department supply to army officers, as a result of a ruling made here to-day, following requests of officers to purchase some of the non-standard cars owned by the War Department. The War Department issued rulings against such sales.

NAVY GETS HISPANO-SUIZAS

WASHINGTON, June 13—The Air Service has transferred to the Navy Department 50 500-hp. Hispano-Suiza engines and spare parts for replacement, according to an announcement of the War Department. The Navy Department acquired the engines and parts at their actual cost to the War Department, which was $227,000. These engines were purchased by the War Department to equip bombing planes.

CODE REGULATING ACETYLENE

MILWAUKEE, June 16—To assist in the work of framing a new code on acetylene gas hazards to promote safety in the use of the process in all its phases, the Industrial Commission of Wisconsin has appointed the following experts as members of an advisory committee: Sidney J. Williams, secretary, National Safety Council, Chicago; P. D. Estes, Chicago, U. S. Bureau of Explosives; W. J. Fairbairn, secretary, Metal Trades and Founders' Association, Milwaukee; Jerry Sullivan, Milwaukee, representing Wisconsin Inspection Bureau; Julius P. Heil, The Heil Co., Milwaukee, representing manufacturers maintaining acetylene gas producer plants; Frank Ohde, Milwaukee, Wisconsin Federation of Labor; Prof. O. L. Kowallke, University of Wisconsin; M. A. Edger, boiler inspector, Industrial Commission, Milwaukee office. Mr. Edger is secretary of the committee.

PONTIAC SPRING REBUILDING

PONTIAC, June 11—The Pontiac Spring Works, a unit of the Standard Parts Co., Cleveland, which was destroyed by fire last March, will be rebuilt. Work will start within three weeks. The building will be brick and steel construction, 186 x 100 ft. A 2-story office building 63 x 87 ft. will also be built. The new plant will cost approximately $100,000. The new unit will house the forge department. The company is employing 300 men and expects to increase to 800.

CHEMICAL CO. IN CANADA

MARIETTA, OHIO, June 14—The Northwestern Chemical Co. opened a factory in Montreal on June 1, to take care of its Canadian business.

DIVIDENDS DECLARED

Michigan Drop Forge Co., Pontiac, monthly dividend of 15 cents a share on common stock, payable July 1 to stockholders of record June 15. An extra dividend of 10 cents a share has been declared payable on same terms.

Reo Motor Car Co., Lansing, regular quarterly dividend, 2½ per cent on common stock, payable July 1 to stockholders of record June 15.

95 Per Cent of Claims Adjusted in Detroit

Aircraft Contracts Valued at $50,000,000—75 Per Cent Ordnance Claims Settled

DETROIT, June 16—Ninety-five per cent of all claims before the adjustment officials of the Bureau of Aircraft Production have been settled. In the Detroit district 75 per cent of the ordnance claims have been settled. All of those remaining are in the process of adjustment, but it may be August 1 before final payment is made.

It was stated to-day that Fisher Body, Wilson Body, Packard, Lincoln, General Motors, Cadillac, Ford Motor, and all other big claims, with the exception of Willys-Overland, had been approved at Washington and paid. The Willys-Overland claim is delayed by incomplete documents, consequent on distractions due to labor troubles. Adjustment is expected within a few days. No figures are given out here on any of the claims.

The claims board of the Bureau of Aircraft Production did not handle as much cash as it thought it would. It was estimated by aircraft officials that at least $300,000,000 would be paid out to cover this district. Not including building and construction, claims which were handled by another board, payment of claims due to cancellation was approximately $60,000,000. Building, construction and equipment claims, which were settled in Washington, totaled approximately $50,000,000, aircraft officials estimated.

There were approximately 800 aircraft contracts in the Detroit district. Of this number, 50 were prime contract claims, the rest sub-contract. The total completed value of all aircraft contracts here was $500,000,000.

The big problem now before both boards is the disposal of material. Separate departments have been established for this work. Machines, equipment and material on hand will run high into the millions. An inventory is being taken. A great portion of this material is of great value. Some of it is worthless. Officials say it may take a year before all material is disposed of.

The Aircraft Board is moving from its offices in the Ford Service Building to the new Saxon plant, which the government leased at the outbreak of the war as a supply depot. It is now being converted into a warehouse for machines and material. The lease runs almost a year.

European Demand Is for Low and Medium Priced Cars

C. C. Hanch, in Report to N. A. C. C., Sees Big Market There If Restrictions Pass

War Departments in Those Countries Not Selling Equipment to Public

NEW YORK, June 16—Europe (without restrictions) is considered by C. C. Hanch, secretary of the National Automobile Chamber of Commerce, the greatest market for automotive apparatus outside North America, according to his report to the N. A. C. C. after his investigation of conditions in Great Britain, France and Italy for four months.

The greatest market in these countries will be for low priced and medium priced cars, such as four-cylinder types at $1,200, or less, and six-cylinder types at $1,600, or less, with a limited demand for high priced American cars, much the same as there is a limited demand for high priced European cars in America.

The possibilities of these countries for absorbing motor cars cannot be calculated entirely on a population basis, as the consensus of opinion is that the ratio of car population cannot be so high in European countries as in America. Notwithstanding the fact that comparisons may not be of value, Mr. Hanch has compiled figures on several of the European countries which are of interest.

Country	Population	Number of Cars	Car-Population Ratio
Great Britain	45,000,000	200,000	1 to 225
France	40,000,000	100,000	1 to 400
Italy	35,000,000	50 000	1 to 840
Belgium	7,000,000		
Total	127,000,000	350,000	1465

Production in 1918

During 1918 the British manufacturers produced 3937 vehicles consisting of passenger car chassis, military cars, ambulances, etc. Only a very few of the manufacturers were permitted to engage in this manufacture. The practical prohibition of the use of motor cars in England during the war makes it certain that even to-day there are fewer cars in use by civilians than there were in August, 1914.

There is a great deal of money in circulation in Great Britain and a strong demand for motor vehicles of all kinds. It is doubtful whether the British manufacturers can turn out within the next 2 years the number of motor vehicles needed by the public during the next 6 months. According to Mr. Hanch, only two of the British manufacturers of passenger cars are ready to make deliveries in any appreciable quantities.

In France, at the beginning of the war, the 100,000 motor vehicles in use were classified approximately as follows:

Passenger cars for business use	48,512
Passenger cars for general use	42,447
Motor trucks	6,000
Total	96,959

In August, 1914, the French Government requisitioned 40,000 passenger cars and 6000 motor trucks and if we deduct these from the total there remains 50,959 in the hands of the French public.

In addition to this number the French Government is reported to have in its possession 50,000 vehicles. Of these, one-half are in good condition and the remainder must be repaired.

If the 25,000 vehicles in good condition were immediately available for civilian use it would make 75,959 vehicles, and if the remaining 25,000 were repaired and turned over to the public a total of 100,959 would be available, which is approximately the same as in the hands of the public at the beginning of the war. These figures indicate that there should be a strong demand for motor vehicles in France and Mr. Hanch thinks the French manufacturers are over-estimating their ability to meet this demand.

Italian and Belgian Situation

Situations in Italy and Belgium are handled as one in Mr. Hanch's report, as he was not able to get accurate information on the number of vehicles in each country. Assuming that the Belgian vehicles were practically eliminated, the figures largely apply to Italy. The ability of the Belgian factories to cope with conditions has been shown in the recent articles in AUTOMOTIVE INDUSTRIES by W. F. Bradley, who visited these factories.

Mr. Hanch is of the opinion that a considerable field for the sale of motor trucks exists in Europe, especially for medium priced trucks of good quality.

In Great Britain, the total delivery of motor truck chassis for 1918 was 11,244, practically all of which were for military use. To-day the British military authorities hold 82,000 trucks, and it has not been indicated how many of these will be disposed of to the public, but estimates are that 80 per cent could be repaired.

France, at the beginning of the war, had 6000 motor trucks, which number has been very greatly increased by purchases from Italy, Great Britain and the U. S. A. for war uses. Mr. Hanch does not give any estimate as to the number of trucks at present held by the French military authorities or any indication as to what disposition is to be made of them.

Nothing with regard to the Italian truck situation is contained in his report.

BOOSTING NIGHT PRODUCTION

LANSING, Mich., June 17.—The Gier Pressed Steel Co. is increasing its night force and will boost night production. Day production was up to capacity several months ago.

8-Hour Day Brings Strike in France

Shops Closed Following Dispute Over Pay of Piece Workers

PARIS, June 3 (*Special Correspondence*)—A strike was declared yesterday throughout the entire engineering industry of Paris and neighborhood. This comprises all the automobile and aviation factories and affects 150,000 work people.

The cause of dispute is in the application of the 8-hour day. A few weeks ago, an agreement was arrived at between workmen and employers in the engineering trade whereby the 8-hour day should be adopted before the new French law went into effect. It was agreed that there should be no reduction in pay in consequence of the shorter work day. On the other hand, the workers agreed to speed up so that the same output should be obtained with 8 hours labor as with 10.

Some of the factory managers refused to increase piece wages, as they claimed that, the same output being assured, workers on piece would not suffer any loss. The men pointed out that until more modern machinery is adopted, and better shop methods put into force, it is impossible for them to increase the amount of work performed: therefore, the adoption of the 8-hour day is for them equivalent to a reduction in wages.

The men claim that the standard wage for skilled workers in the engineering industry should be 150 francs ($30) a week; semi-skilled laborers claim $26 a week and laborers $22 a week.

It is not so much, however, a question of standard wage which has caused the dispute as the remuneration of piece workers under the 8-hour scheme.

In the automobile and aviation industry, dissatisfaction appears to be greatest at the Renault, Panhard and Farman factories. The majority of the automobile factories around Paris closed yesterday, among those affected being Lorraine-Dietrich, Unic, Clement-Bayard, Darracq, De Dion-Bouton, Hotchkiss, Citroen, Mors, Charron, Saurer, Aries, Hispano-Suiza and Gnome.

In certain individual cases the factory owners have, by explaining the situation to their men, induced them to remain at work. One instance of this is the Delage factory, which, this morning, was working at full speed, although most of the neighboring establishments were closed.

TRANSPORT FACTORY

MOUNT PLEASANT, Mich., June 16—A $175,000 factory will be built for the Transport Truck Co. and is to be completed by the middle of August. It will be of brick construction, with concrete floors and steel sash. It will have a saw-tooth roof. The office will be in the factory proper until a new office building is put up. Work has already started on the new plant.

Peugeot Victory Surprises French

Change of Wheels Made by Thomas Blamed for Defeat of Ballot Cars

PARIS, June 3 (*Special Correspondence*)—There is much surprise in French automobile racing circles at the result of the Indianapoils 500-mile race. It was believed that the struggle would be a close one, but no one here expected that the five year-old Peugeot cars would figure prominently in a contest 500 miles in length. The winner was looked for in one of the four Ballot cars, the new Duesenbergs, or in De Palma's Packard.

There is no doubt that the maximum speed of these cars, which embodied an accumulation of five years' experience and experiment, is much higher than that of the pre-war Peugeots. The new Ballot cars are the latest word in French automobile engineering, and for them to have been beaten seems to implicate poor management at the last moment.

Charles Faroux, who is undoubtedly the most competent French critic, throws all the blame for the Ballot failure on René Thomas. Faroux explains that, owing to wrong information given by Thomas, the cars were sent into the race with too high gear ratio. Thomas cabled for authority to change wheels and tires for a smaller diameter. This was granted for Thomas's car only, and refused for the three others. Notwithstanding this, the wheels on all cars were changed. This brought about considerable tire trouble and, it is believed here, caused the cars to lose the race. Faroux writes on this point as follows:

Asked to See Duplicate Orders

"The thing is so extraordinary that I asked to be allowed to see duplicate copies of the orders given by Ballot to his men. Here is a case of an important manufacturer who has accomplished an unprecedented task by building four special cars in less than 15 weeks. He had the service of Henry, one of the best engineers, who took the trouble to plot the power curve of the motor and to calculate the right gear ratios. All of this is swept away, annihilated, reduced to nothing by reason of the fad of a driver, who needs a strong master over him.

"Fortunately Peugeot saved French honor; or the consequence of the undisciplined Thomas might have been still worse. I affirm that neither Wagner, nor Guyot, nor Bablot would have made such a mistake. But Thomas is terrible. He is his own worst enemy. As a driver he can bear comparison with the best; his daring, his accuracy, his coolness in a race place him in the first class; but he has already lost a number of races by reason of his mania for tinkering at the last moment.

"Three elements are necessary in order to win a race: the manufacturer, the engineer, the driver. Ballot built wonderful cars, which started favorites in the race; Henry has already shown his qualities; Thomas might have been the winner if he had been content to remain a race driver. Personally, I am not surprised. Talking with friends on Saturday regarding this race, I made the following remark:

"'Ballot would certainly be the winner if he had any other team captain than Thomas; but with Thomas there is always the danger of some freak idea at the last minute. Thomas, the race driver, is fine, but I have no confidence in Thomas the mechanic.'

"I have elaborated this point because it is full of lessons for our manufacturers. I have no reason to fear regarding the Ballot cars; they will show their worth on the first occasion. And if, on that date, Thomas is satisfied to stick to his steering wheel, which he handles in a masterly manner, he will doubtless be the winner. It is a debt he owes to his employer."

—

SHELDON ENTERTAINS S. A. E.

WILKES-BARRE, PA., June 17—The Pennsylvania section of the Society of Automotive Engineers was entertained at its annual meeting here on Saturday as guests of the Sheldon Axle & Spring Co. About 60 members of the S. A. E. inspected the Sheldon plant in the morning and were then taken out to dinner. A short meeting was held after the dinner, at which the by-laws of the main section were unanimously adopted and the results of the election of new officers announced as follows: Chairman, I. K. Brombaugh, Autocar Co., Ardmore, Pa., succeeding C. Mussleman; secretary, G. W. Smith, Victor Talking Machine Co., succeeding H. E. Rice, and treasurer, William H. Sackman, Light Foundry & Manufacturing Co., succeeding George Newkirk.

—

CASE AGAINST PREST-O-LITE

WASHINGTON, June 14—The chief allegation in the complaint filed last week by the Federal Trade Commission against the Prest-O-Lite Co., Indianapolis, concerns the deposit for steel cylinders required from the company's dealers. The company must file answer by July 24 to the charge that its practices are in restraint of trade under the Clayton Anti-Trust Act.

The complaint alleges that the Prest-O-Lite Co. makes contracts with purchasers provided that the buyer will make deposit on the steel cylinders in which the gas is delivered and that, when the cylinders are exhausted, they must be returned to the Prest-O-Lite Co., which agrees to supply other filled cylinders for the additional price of gas contained, but does not provide for any refund to the buyer of his original deposit on the cylinders except where the Prest-O-Lite Co. "unreasonably refuses" to issue any further cylinders to the purchaser.

These operations, the Commission alleges result in loss to the purchaser of the cash deposits in the event that he does not require further acetylene gas or buys it from a competing manufacturer.

The complaint also alleges that the statement in the contract to the effect that it is not practical or safe to refill the cylinders through any company other than the Prest-O-Lite Co. is a subterfuge to obtain monopoly. The cylinders, the Commission states, can be and have been safely refilled by other concerns.

Program of S. A. E. Summer Meeting

Technical Sessions in Mornings—Wireless Telephony and Gas Warfare Subjects for Evening

NEW YORK, June 18—The New York members of the Society of Automotive Engineers will leave for Ottawa Beach, Mich., in a special car attached to the Wolverine, over the New York Central at 5 p. m., Sunday. There is promise of a large attendance. The arrangements at Ottawa Beach are working out well and there is every prospect of an excellent meeting. The program to date, with the social features eliminated, follows:

Monday, 10 a.m.—Standards Committee meeting. All members invited. The following Divisions are expected to present reports: Aeronautic, electrical equipment, iron and steel, lighting, miscellaneous, motorcycle, shaft fittings, stationary engine and lighting plants, tire and rim, tractor, transmission and truck standards. 2 p.m.—Continuation of Standards Committee meeting. 4 p.m.—Meeting of Council. 8 p.m., Business Session—Presidential address, treasurer's report, report of Membership Committee, election of Nominating Committee members, report of Meetings Committee, discussion of future policy with respect to parts and accessory exhibits at summer meetings, new business, report of Standards Committee.

Tuesday, 10 a.m., Truck and Fuel Session—"Tests of Truck Axle Worms and Bearings," K. Heindlhofer; "Motor Truck Ability and Its Relation to Trend of Truck Design," L. P. Kalb; "Steel Truck Wheels," P. W. Klinger; "Motor Fuel Problem," Dr. Joseph E. Pogue; "Protective Coatings for Metals," E. T. Birdsall. 8 p.m.—Lecture on Wireless Telephony (to be accompanied by demonstration), E. H. Colpitts, assistant chief engineer, Western Electric Co.

Wednesday, 9:30 a.m., Passenger Car Session—Symposium and discussion on the future passenger car, E. H. Belden, H. M. Crane, L. H. Pomeroy, H. C. Snow, W. B. Stout: "Liberty Engine Materials and Their Use in Automotive Industry," Harold F. Wood; "Load Carrying Possibilities of Angular Contact Type Ball Bearings," F. C. Goldsmith. 8:30 p.m.—Talk on Gas Warfare by Dr. John Johnston, Professor of Chemistry, Yale University.

Thursday, 9:30 a.m., Army and Navy Session—"Development of 'NC' boats and Other Naval Aircraft," Commander J. C. Hunsaker, U. S. N.; Future Relations between the automotive industry and various army departments are to be outlined by representatives of the Department of Military Aeronautics, the Ordnance Department and the Motor Transport Corps. 2 p.m.—Exhibits of tanks and other automotive war equipment in action. 8 p.m.—Talk on experiences with A. E. F. and the armistice commission (to be illustrated by motion pictures), Lieut.-Col. A. J. Slade, U. S. A.

Friday, 9:30 a.m., Engine and Tractor Session—"Working Processes of Future Combustion Engines," Prof. C. A. Norman; "Relation of Tractor to Implement," Prof. E. A. White; "Electric Heat Treatment of Steel," H. P. MacDonald.

Reservations to date total 681.

Daniels Urges Aviation Fund

Reduction of Appropriation Calls for Protest from Navy Department Head

WASHINGTON, June 16—The reduction of Naval appropriations from $45,000,000 to $15,000,000 by the House Committee of Naval Affairs is meeting with strenuous objection from Secretary Daniels. He is carrying the fight to the Senate Naval Committee. Secretary Daniels' letter to the Chairman of the Senate Committee states that Great Britain has appropriated $320,000,000 for aviation for the current year for both military and naval purposes, and that the United States Navy should be provided with at least $36,000,000. His letter follows:

"The general board of the Navy, after extended hearings covering the whole field of aviation, recommended a program for the next fiscal year which our experts estimated would require the $45,000,000 originally asked for by me in Congress. I feel very strongly that the figure of $36,000,000 reported by the Senate naval committee during the last session should at least be provided.

"The naval bill as reported to the House has cut the appropriation for Navy aviation to $15,000,000. I deem it my duty to bring to your attention the fact that with this amount Navy aviation will practically 'mark time' during the next year, which should be a year of rapid development, and will be a year of rapid development of this arm of the Navy in countries other than the United States.

"This is sufficiently indicated by the fact that in Great Britain the appropriation for aviation made for the current year amounts in round figures to $320,000,000.

"This includes all aviation for military purposes and should, of course, be compared with the total contemplated appropriations for both Army and Navy in the United States, amounting to something like $30,000,000."

WASHINGTON, June 19—Secretary of the Navy Daniels and naval officers appeared before the Senate Naval Affairs Committee to-day and protested against the reduction of naval appropriations from $45,000,000 to $15,000,000.

Senator Paige, Chairman of the Committee, called a session to-day and stated that he was in favor of restoring the appropriation to at least $36,000,000.

Secretary Daniels declared that the future of the American Navy will be seriously endangered unless sufficient money is provided to keep up with the rapid trend of development in aviation. He stated that plans had been made for a naval aviation force of 563 officers and 4630 men, and a Marine Corps aviation force of 100 officers and 1000 men.

If the appropriation of $15,000,000 is not increased the Marine Corps force would be completely wiped out, and the other organization would be seriously crippled. At present there are 12 naval air stations, four schools and one experiment station, and these will be considerably limited with all experimental work discontinued unless the appropriation is adequate.

MEXICAN PETROLEUM INQUIRY

WASHINGTON, June 14—An official commission from Italy is en route to Mexico to study the Mexican petroleum laws. It is anticipated that other countries will also send delegates.

NO MOTORCYCLE PURCHASE

WASHINGTON, June 14—The purchase of motorcycles for the War Department has been completely discontinued and instructions have been issued to the chiefs of the various bureaus that no more motorcycles are to be purchased without first securing the permission of the Secretary of War.

REDUCE WAR VEHICLE ORDERS

WASHINGTON, June 13—The contracts for motor vehicles placed by the War Department during the war and amounting in all to $416,528,000 on Nov. 11, 1918, were reduced by cancellation or completion to $17,970,000 on May 17. Of the total 67 per cent was cancelled, 29 per cent filled, and 4 per cent still remains on order.

TIN IMPORTS PERMITTED

WASHINGTON, June 17—Importations of pig tin and all metal alloys containing tin, including tin drosses, tin oxides, solder drosses, type metals, antifriction metals, waste metals, and other metals containing tin may now be licensed, according to a ruling of the War Trade Board, subject to the following conditions and limitations: That such licenses will permit the importation only of shipments made from points of origin on and after June 30, 1919; and that such import licenses will not be valid for entry until August, 1919.

TRAILER OWNERS FIGHT BILL

BOSTON, June 16—Owners of trailers are making an active fight on the proposed motor vehicle tax bill reported by the Committee on Roads and Bridges as House Bill 1748

It develops that this bill requires trailers fitted with solid rubber tires to pay the same tax as motor trucks, and that steel tired trailers pay double this tax. A 5-ton rubber tired trailer will be taxed $100 a year if this bill becomes a law and a 5-ton steel tired trailer must pay $200, or 15 per cent of the cost of the trailer annually.

AXLE FOR BENTON HARBOR

BENTON HARBOR, MICH., June 16—The Frederickson Axle Co. has purchased the Cutler warehouse here, where it will locate its plant, employing 40 to 50 men.

Argentina to Amend 1905 Trademark Law

New Bill Will Protect All Trademarks Recognized Through Treaty by U. S.

WASHINGTON, June 16—In order to protect trademarks and commercial names made and signed in Buenos Aires, Argentina, a bill has been introduced into Congress amending the trademark law of 1905 so that any trademark, registered in an international office or bureau, and recognized through treaty by the United States, will be considered a trademark for which application for registration has been filed, and on which the Patent Office can act accordingly.

The bill allows the same privileges as are afforded citizens of the United States on the application for registration of a trademark filed in an international bureau, provided that the application is made within six months of the date of original filing in the foreign country, and has been actually registered by the applicant in the country in which he is located.

Provision is also made to allow any individual to apply for cancellation of a trademark registration whenever he regards himself as being injured by it. Upon such application for cancellation, the Commissioner of Patents is authorized to investigate and withdraw the registration.

There is also a provision that any person who uses a deception in the selling of commodities by the use of a trademark which tends to falsify the origin of the merchandise when it is sold, either interstate or for export, will be liable for damages at the hands of anyone doing business in the locality that is falsely indicated as that of origin.

PATENT SYSTEM CHANGES

WASHINGTON, June 14—The patent committee of the National Research Council has approved proposed legislation to "increase the efficiency of the Patent Office in handling inventions and patents." The program calls for the establishment of a single court of Patent Appeals to take over the appellate jurisdiction now lodged in the nine independent Circuit Courts of Appeal, an increase in the personnel and in the salaries and a change in the law relating to the damages and infringement suits.

FOSTERING HOLLAND TRADE

NEW YORK, June 14—The Commercial Department of the Koninklyk Gezantschap der Nederlanden has been formed recently to foster trade between the United States and Holland, and is in a position to give commercial information about trade between the two countries to American merchants. Further information can be obtained from D. Andreae, Commercial Attaché, Koninklyk Gezantschap der Nederlanden, Washington, D. C.

Clifton Outlines the N. A. C. C. Work

Annual Address of President Shows Co-operation with Other Organizations

NEW YORK, June 16—The annual address of President Charles Clifton of the N. A. C. C., which has just been made public, tells some very interesting facts concerning the activities of the chamber and of the co-operation of the chamber with other automotive organizations.

As to the question of admitting tractor manufacturers to membership, the following paragraph is quoted from the address:

"A number of the tractor manufacturers have expressed the wish that they be admitted to the Chamber so as to take advantage of various departments like patents, traffic, legislative, publicity, etc. We find no uniform feeling among members interviewed in favor of such a plan, but later in the day all members here will be asked to express their thought on it."

There was some discussion, but no poll was taken.

Cross Licensing

The cross licensing agreement as to patents is referred to in the address. Since this address a motion has been filed to dismiss this suit, the attorneys for the Chamber setting forth that the Locomobile suit should be directed against other firms in the agreement and not against the Chamber. Of the suit, Mr. Coffin said:

"After operating successfully for four years, the Cross-Licensing Agreement has been made the subject of a suit by the Locomobile Company of America, which expresses the wish to be relieved of its obligations under it. The whole matter has been placed in the hands of Mr. Frederick P. Fish, who drew up the original Cross-Licensing Agreement. Mr. Riker, vice-president of the Locomobile Company, was a member of the Patents Committee during the formative period of the Cross-Licensing Agreement. The agreement generally has been looked upon as a broad piece of co-operative work, with no objection from any other source. Makers have gone on inventing and putting the results of their inventions into the Cross-Licensing Agreement. A big maker expressed it well the other day when he said that he was glad to take out patents as a protection from outsiders and to put them into the Cross-Licensing Agreement because his company always had at least a year's start on everybody else in their use, while in return they were getting the results of inventions by other parties to the agreement.

"The need for makers to continue inventing and taking out patents is evidenced by the fact that in the Cross-Licensing Agreement are 600 patents, while on file in our Patent Department are 117,000 patents (copies brought from Washington to our office here), all of which affect the automobile industry in some way. When the Attorney General of the United States was passing on the Cross-Licensing Agreement of the Aircraft Manufacturers, he had before him copies of the N. A. C. C. agreement and there never has been a suggestion from him that it was other than a legal document which attempted to lessen litigation. He did not object to a similar agreement, with many additions involving large sums of money, being put into operation by the aircraft manufacturers."

Listing Motor Vehicles as Commodities

Concerning the effort to have motor vehicles listed as commodities, so that the banking paper will be subject to rediscount in Federal Reserve Banks, the address says:

"Some time ago a presentation was made to the Federal Reserve Board with a view to having motor cars and motor trucks classed as marketable staples and the bankers acceptances in connection with them acceptable to the Federal Reserve Banks for rediscount, thus saving one-half to one per cent. While the board was unable to rule favorably on this subject and thus put the motor vehicles in the class with cotton, coffee, wheat and similar commodities, there was highly favorable expression of the importance of the industry, with a definite statement that the ruling did not detract from the worthiness of motor cars as security. Working with some of the western banks, a uniform campaign was started some time ago to insure a higher appreciation by the local banks throughout the country, of the products of our makers, to the end that even better accommodations can be given to dealers than during the past. Our interests lie with dealers and the Chamber's efforts are always directed toward those things which make for the dealer's prosperity."

Co-operation with Other Associations

On the subject of co-operation with other associations, Mr. Coffin says:

"We have co-operated in every way with other organizations in our line, in some cases contributing substantially to the helpful work that they were doing. These contributions include $10,000 to the American Automobile Association, $7,500 to the Society of Automotive Engineers, $5,000 to the National Industrial Conference Board, $1,000 to the Associated Advertising Clubs, $1,000 to the Highways Iudustry Association, $500 to the National Association of Credit Men, and $700 for membership in the U. S. Chamber of Commerce.

"In addition it has been felt that the helpful work of the dealers in New York and Chicago with whom we co-operate warrants their participation in the national shows we hold in these two cities. The dealers in Chicago were strongly opposed to conducting another show, declaring that only a national show brought the desired results for them and for the industry, with similar expressions from many of the dealers in New York. All felt, however, that their co-operation and help warranted their participation, and I know that members generally will agree that the directors have given only a proper recognition of their importance to our industry.

"It has been our pleasure to co-operate during the past year with the National Automobile Dealers' Association, Motor and Accessory Manufacturers, Automotive Jobbers' Association, Society of Automotive Engineers, American Automobile Association, National Traffic Association, Highways Industry Association, National Industries Conference Committee, Associated Advertising Clubs, National Association of Credit Men, and Chamber of Commerce of the U. S., together with a score or more of other organizations, all having interest in the making, selling or using of motor cars."

Menacing Legislation

Mr. Coffin points out that there is great need for legislative work, and declares means should be found to make the automotive interests a common one. He says:

"There is still more or less menacing legislation in the air. We have 6,000,000 owners of motor vehicles and while we have not hesitated even to advocate increased registration fees when the money is put on the roads, we do object to the singling out of our industry for taxes not placed on other users of the highway. We advocate the uniform bill prepared by the Highways Industry Association, the main points of which have been printed and distributed by the American Automobile Association, and which calls for certain limitations as to weights and sizes of vehicles for use on the road, together with proper sizes of tires and proper speeds. We have advocated taxes not in excess of 25c per horse power and 25c per hundred pounds in weight. Our committee has appeared and helped in various states throughout the country where the local associations require assistance. We have supplied literature and experts to give information to the legislators but your directors have never deemed it advisable to contribute financially to such work."

MOTOR VEHICLES RETURNED

WASHINGTON, June 14—The American Expeditionary Forces have been instructed to return all class B 3-ton standardized army trucks to the United States, together with all new truck dump bodies and all Dodges and Cadillacs that are boxed or crated.

The final disposition of these has not yet been determined, but it is anticipated that they will form a part of the permanent equipment of the United States Army. A total of 18,826 class B trucks, 2952 Dodges and 1399 Cadillacs were shipped to France up to the signing of the armistice. Many of these have been destroyed in battle or through wear and tear.

Effort to Reduce Car Taxes Abroad

Situation in Europe as Presented by C. C. Hanch—Gas Problems

NEW YORK, June 16—Interesting comment on the taxes on motor cars in European countries is contained in the report C. C. Hanch read to the National Automobile Chamber of Commerce on his return from a four months' investigating tour in Europe.

The annual taxes in Great Britain are tabulated as follows:

	About
Not over 6½ hp.	$10.50
Over 6½ hp. to 12 hp.	15.75
Over 12 hp. to 16 hp.	21.00
Over 16 hp. to 26 hp.	31.50
Over 26 hp. to 33 hp.	42.00
Over 33 hp. to 40 hp.	52.50
Over 40 hp. to 60 hp.	105.00
Over 60 hp.	210.00

On the subject of running cost Mr. Hanch says:

"Prices of gasoline in England vary from 75 cents to $1 per gallon, according to quality. Of this price until lately the tax has been 24 cents per gallon, but the surtax of 12 cents per gallon has recently been removed, leaving the Government tax of 12 cents per gallon.

Tax in France and Italy

"FRANCE—Purchasers of both new and second-hand cars pay a luxury tax amounting to 10 per cent of the value of the car. The annual or circulation tax is based on horsepower and varies in different places. As an example, the tax on a 15 hp. car varies from $35 to $100 according to locality. The present price of gasoline is $1.08 per gallon, of which 32 cents per gallon is tax. There is also an 80 per cent war profits tax. The prewar price of gasoline in France was 56 cents per gallon, of which 32 cents per gallon was tax.

"ITALY—The annual or circulation tax for an average car is about $120 per year. The tax on gasoline is about $4.60 per quintal, of 220 pounds, or about 12 cents per gallon."

As to efforts to obtain a reduction in taxes, Mr. Hanch says:

"The general Congress of the Inter-Allied Automobile Manufacturers held in Paris on March 5 and 6, 1919, decided that efforts should be made simultaneously in all Allied countries to obtain a reduction of annual taxes and license fees, these efforts to be supported by publicity pointing out among other arguments the following facts:

"That the automobile industry of the allied countries took first place in the intensive production of war supplies.

"That motor transport service rendered to the fighting armies was of the greatest importance.

"That transportation of passengers and materials by motor vehicles is now one of the necessary conditions of modern life.

"That the use of motor vehicles generally and for a long time past has ceased to be a luxury and has become the auxiliary of trade and industry.

"That the proceeds of license fees and taxes should be used for the maintenance and betterment of roads."

Used Passenger Cars Have Fabulous Value in England

Advertisement in London Times Offering Used Cars for Sale at Prices Doubling and Tripling Cost When New—French and Italian Models Included

LONDON, ENGLAND, May 27—Today's London *Times* carries an advertisement offering a number of used passenger cars at prices which are calculated to stagger motoring humanity when compared with the prices at which the same cars were sold when new. The explanation of the enormous increase is found in the fact that England is suffering from a car-famine of unparalleled severity. No passenger cars have been built, except for war service, for over four years, and one of the first military orders issued in August, 1914, commandeered all privately owned cars for army service.

The prices given in the table below have been reduced to dollars from pounds sterling at the current rate of exchange in New York.

*Used Car Price in 1919	Make and Type	Year	Original Price When New
$23,150.00	Rolls-Royce, 5-pass.	1915	$6,250.50
21,992.50	Rolls-Royce, All-weather	1915	6,945.00
20,140.50	Rolls-Royce, 5-pass.	1915	6,250.50
19,677.50	Rolls-Royce, 4-pass.	1914	6,250.50
18,520.00	Rolls-Royce, 5-pass.	1914	6,250,50
18,520.00	Rolls-Royce, All-weather	1914	6,482.00

*To arrive at the cost of any of these used cars delivered in the United States, add 45 per cent import duty; also freight and insurance. Possible loss through fluctuation of exchange rate would be another factor for consideration.

†Special models; original prices not obtainable.

DISPOSAL OF WAR VEHICLES

WASHINGTON, June 16—The transfer of the 39,100 surplus motor vehicles to other government departments as approved last week by the Director of Sales of the War Department included 3,600 motorcycles, 5,500 passenger cars and about 30,000 trucks. The Post Office Department will receive 10,064 of these vehicles, the Public Health Service 1,396, and the Bureau of Public Roads, Department of Agriculture, 27,983.

ENGLAND LICENSES 411,791 CARS

LONDON, ENGLAND, May 22—Car licenses in England, as reported including the 6th and 7th issues, in the Board of Trade Journal, total 411,791, which seems to be a fair estimate of all the cars in use at present in the country. Complete figures for the 6th and 7th issues follow:

	6th issue	7th issue
Form 1, Private cars	93,947	
Form 1A, Private cycles	56,309	
New series: 1 and 1A private cars and cycles	76,605	
Form 2, Doctors' cars	12,073	
Form 3, Hackney vehicles	25,827	
Form 4, Commercial vehicles	47,388	37,837
Form 5, Industrial processes	61,805	
Total	373,954	37,837

Allied Control of German Aeronautics

Peace Treaty Provides for Aeronautical Inter-Allied Commission—Restrictions on Trade

WASHINGTON, June 16—Complete control of German aeronautic activities by an Aeronautical Inter-allied Commission is forecast in a copy of the peace treaty which was published in the Congressional Record.

Clauses provide that the armed forces of Germany must not include military or naval air forces, that Germany may maintain a maximum of 100 seaplanes or flying boats up to Oct. 1, 1919, to be used exclusively for searching for submarine mines. These boats may carry one spare engine in addition to the engines installed. No dirigibles shall be kept. Within two months after the signing of the treaty the personnel of the German air forces on land and sea must be demobilized. Up to Oct. 1, 1919, a total organization of 1,000 men may be maintained.

The Allies retain freedom of passage through the air over Germany until after the complete evacuation of German territory by allied troops. Complete prohibition of the manufacture or importation of aircraft or parts including engines is ordered for six months following enforcement of the treaty, and on the coming into force of the treaty all military and naval aeronautical material, excepting that mentioned above, must be delivered to the allies within three months.

This material will include completed airplanes and seaplanes as well as those partly manufactured or assembled, dirigibles completed and partially completed, plans for the manufacture of hydrogen, dirigible sheds and shelters of every kind for aircraft, aircraft engines, nacelles and fuselages, all aeronautical armament, munitions, instruments, wireless and photographic apparatus and cinematograph apparatus for use on aircraft.

The German Government must further extend every aid to the Aeronautical Inter-allied Commission for the execution of these clauses. It will further give every aid to make inventory of the aeronautical material in German territory, to inspect airplane, balloon and engine fixtures and aircraft armament fixtures, to visit all aerodromes, sheds, landing fields, and to authorize, where necessary, removal and delivery of material.

The German government must further furnish the Commission all information and legislative, administrative or other documents which the Commission may consider necessary to insure the complete execution of the air clauses of the treaty and particularly a list of the German air service personnel and of the existing material as well as that in process of manufacture or on order and a list of all establishments engaged in aviation manufacture and of all sheds and landing grounds.

That the export of American automotive products into Germany and German territory will not be prohibited is assured by the clause providing that Germany will not prohibit the importation of any product from any of the allied countries without equally extended restriction to the importation of like products from any other states or foreign countries.

Protection against high and partial tariffs is insured by the clause which prohibits Germany from attaching such duties to products from any of the allied countries in excess of those duties placed on the same goods from any other foreign countries. Furthermore, Germany undertakes to make no discrimination against the commerce of any allied or associated country as compared with the commerce of any other foreign country, either by direct or indirect means, including customs regulations, methods of verification, conditions of payment, etc.

Furthermore, Germany is forbidden to impose any restriction on the exportation of any commodities from her territory to any of the allied countries without placing that same restriction upon the same commodities when exported to any foreign country and grants every privilege in regard to import, export or transport of goods given to any foreign country equal to the allied countries.

Protection against the sale of articles which bear trademarks or descriptions fraudulently is prohibited.

U. S. LOST 357 PLANES

WASHINGTON, June 16—The American Air Service inflicted double the loss upon the Germans which they suffered in airplanes and balloons. A total of 755 enemy planes and 71 balloons were destroyed. The American losses were 357 planes and 43 balloons.

AIR APPROPRIATION OF $13,000,000

WASHINGTON, June 16—Appropriations for the Army Air Service have been placed at $13,000,000 by the House Military Affairs Committee. It is claimed by military officials that this sounds the knell of aviation in the United States because it is insufficient.

AERONAUTICS IN COLLEGES

WASHINGTON, June 14—Aeronautics has been established as one of the optional subjects at several universities in England, according to a trade report, and chairs of aeronautics have been established at the universities of Cambridge and London. Aeronautical scholarships have been instituted. Several English schools have secured airplanes, engines and other equipment for their engineering classes.

TACOMA RACES

TACOMA, WASH., June 14—Eddie Rickenbacker will be official referee July 4 in the events on the speedway here. Louis Chevrolet, Dario Resta, Cliff Durant, Eddie Hearne and Ralph Mulford will take part in the races.

Exports of Tractor Engines During April, 1919

Countries	Number	Value
Belgium	6	$8,461
Denmark	49	48,200
France	542	536,067
Italy	83	164,715
Norway	42	36,689
Spain	10	16,030
England	217	136,154
Ireland	22	23,515
Canada	1,005	842,266
Costa Rica	1	1,685
Honduras	4	9,545
Mexico	67	53,059
Jamaica	2	3,244
Trinidad and Tobago	1	1,744
Cuba	34	27,350
Virgin Islands of United States	1	777
Argentina	100	82,941
Brazil	3	3,570
Chile	1	571
British Guiana	12	15,790
Peru	25	37,026
Venezuela	1	1,326
Other British East Indies (Exc. British India and Sts. Settlements)	2	1,552
Dutch East Indies	...	....
Japan	1	678
Australia	59	68,851
New Zealand	14	15,874
Philippine Islands	...	....
British South Africa	1	369
Total	2,305	$2,138,049

During wartime we exported thousands of tractor engines. Most of these were used in connection with the hauling of heavy field guns. Under post-war conditions figures are well maintained and the engines are being used for farm tractors.

REORGANIZE AIR COMMITTEE

WASHINGTON, June 13—The National Advisory Committee for Aeronautics has been reorganized so that the executive committee will include 6 sub-committees on aerodynamics, power plants for aircraft, materials for aircraft, personnel, buildings and equipment, publications and intelligence and governmental relations.

The committees on aerodynamics, power plants for aircraft and materials for aircraft will attack the various problems relating to these subjects, coordinate research, act as mediums for the exchange of information and conduct laboratory tests.

The committee on personnel, buildings and equipment will initiate projects concerning the erection or alteration of buildings. The publications and intelligence committee will collect and classify knowledge on aeronautics, including the results of research and experimental work done in all parts of the world, supervise the office of Aeronautical Intelligence and the foreign office in Paris.

AIRCRAFT CONTRACTS SETTLED

WASHINGTON, June 16—Contracts with aircraft manufacturers have in great part been settled by the War Department and will all be completed within the next ten days.

CHANGE IN FOREIGN FORD POLICY

LONDON, June 1—The announcement that Sir Percival Perry is retiring as managing director of the Ford interests in the United Kingdom is taken as an indication that there will be a change in the Ford policy on this side. It is believed that the English practices will be made to correspond with those in America.

The British management of the Ford interests has allowed certain picked territories exclusively to a few distributers, leaving it to them to adjust commissions with sub-dealers. This has caused a great deal of dissatisfaction among the smaller dealers as the discounts have ranged from 7½ to 10 per cent for the smaller dealers to as high as 20 to 25 for the big dealers. It is believed that the American Ford organization will take a controlling hand in the management of the selling policy over here.

It is understood that Sir Percival Perry will retain his interest in the Fordson plant so that he will continue to be associated with the Fords.

—

Asher Golden has been appointed by the Compagnie d'Applications Mécaniques, Paris, its exclusive agent in the United States for the sales of RBF bearings and retainers.

Miss Ruth Edwards, who has been treasurer of the Bantam Ball Bearing Co, Bantam, Conn., for the past three years, has resigned her position. She has been with the company for 12 years.

J. W. McCabe, formerly district sales manager of the Chicago Pneumatic Tool Co. at Buffalo, has been made special representative for that company's foreign trade department, and is about to make a trip through the Orient.

George W. Rowell, newspaper man, and formerly secretary and manager of the Upper Peninsula Development Bureau, has been made publicity and advertising manager of the Lloyd Mfg. Co., Menominee, Mich.

S. A. Schaeffer, foundry superintendent of the Fairbanks-Morse Co., Three Rivers, Mich., has resigned to become assistant superintendent of the Clarage Fan Co., Kalamazoo, Mich. He is succeeded by B. C. Page of Spokane, Wash.

F. L. Sanford will be in charge of the New York branch of the Dort Motor Car Co., Flint, which will be opened shortly in the Ehret Building, 58th Street and Broadway. Mr. Sanford was for several years manager of the Studebaker branch in New York.

DOBLE-DETROIT REORGANIZED

DETROIT, June 17—The Doble-Detroit Steam Car Co. is being reorganized. Details of the reorganization will be announced within 2 weeks. The company recently sold its manufacturing plant, but expects to build another. It is expected that the car will be placed on the market this fall. In the meantime the company will continue the manufacture of the Doble-Detroit heating system.

Men of the Industry

Changes in Personnel and Position

BEACHAM LEAVES BARLEY

E. H. Beacham, assistant to A. C. Barley, president of the Barley Motor Car Co., Kalamazoo, Mich., has resigned and gone to Chicago to accept a post with the Waldon W. Shaw Co., operating the Shaw Taxicab Co. and the Yellow Taxicab Co. He has been acting as general sales manager during the past six months. His successor has not been named.

—

H. L. Hall has resigned as branch manager of the Swinehart Tire & Rubber Co., and will return to the Troy Carriage Sunshade Co., with which he was previously connected for eight years. He will take charge of the Chicago office of the Troy Carriage Co. at 20 East Jackson Boulevard.

Charles M. Prendergast, recently general superintendent of the Briscoe Motor Corp., is general superintendent of the Auto Body Co., Lansing. He succeeds Alex Urquhart, who resigned after 18 years of service to become superintendent of the Lansing Body Co.

J. L. Justice, who for the past three years has been zone supervisor for the Maxwell Motor Co., Detroit, resigned to become general sales manager of the National Wire Wheel Works, Inc. He will have his office in the Book Building, Detroit.

C. E. Wilson, formerly of the Westinghouse Electric & Manufacturing Co., has been made manager of the motor equipment division of the Remy Electric Co., and will have charge of engineering and sales with headquarters in Detroit.

GOODYEAR PANAMA OFFICES

AKRON, June 17—The Goodyear Tire & Rubber Co. has opened central headquarters, with distributing warehouses, at Colon, Panama. J. H. Proeger, who has been branch manager at Havana, Cuba, for several years, is in charge.

The Panama office will serve Costa Rica, Nicaragua, Bolivia, Venezuela, Dutch Guiana, Guatemala, Panama, Chile, Peru, British Guiana, Honduras, Salvador, Colombia, Ecuador, French Guiana and the islands of the West Indies excepting Cuba, Porto Rico and the Dominican Republic.

NEW YORK REPRESENTATIVE

BAY CITY, MICH., June 17—The Machine Tool Engineering Co, 149 Broadway, New York City, will be the sales agent for the Smalley General Co. in New York and New England territory.

NEW BETHLEHEM VICE-PRESIDENT

H. B. Hall has been elected vice-president of the Bethlehem Motors Corp., Allentown, Pa. He will make his office in New York and look after the export activities of the company. He was formerly assistant general sales manager of the Bethlehem Motors Corp. and until recently president of the Chicago-Bethlehem Sales Co., Chicago.

—

Joseph Leopold has resigned as sales manager for the Jones-Motrola, Inc., to become sales manager of the Trego Motors Corp.

DINGEE INVENTOR DEAD

CHICAGO, June 13—W. W. Dingee, one of the pioneers in the manufacture of farm implements, died at his home here on May 25 at the age of 88. He perfected the Dingee horsepower and later was interested in machinery operated by steam. He was connected with the Sawyer Manufacturing Co. when the J. I. Case T. M. Co. purchased it in 1878, and was connected with the Case company until he retired from active business in 1906.

U. S. RUBBER HELPS SUBSIDIARY

DETROIT, June 13—The United States Rubber Co. will spend $3,000,000 this year in extensions and equipment to the works of Morgan & Wright, its subsidiary unit here.

TRACTOR BRAKE AND DRAWBAR HORSEPOWER RATING

(*Continued from page* 1383)

My idea of rating a tractor would be to first use a fixed piston speed in all formulæ and thus establish a brake horsepower which really means something. That is to say, engines so rated could be expected to endure and perform satisfactorily.

For the drawbar rating the S. A. E. or the Government should establish a laboratory equipment suitable for measuring the mechanical efficiency of the transmission, and also for finding the rolling resistance under a certain fixed condition. Each make of tractor could be thus tested, and the mechanical loss in the transmission and the rolling resistance subtracted from the brake horsepower would give a result which would be very close to correct in each special case, and would give manufacturers of lighter weight higher grade machinery actual credit in the rating of the tractor.

In figuring the brake horsepower of any tractor motor a reserve of power of approximately 25 per cent should be allowed for. In other words, if a motor actually develops 40 horsepower at a piston speed of, say, 850 feet per minute, the brake horsepower used in calculating drawbar pull should be 30. There are two reasons for this: First, the motor would always have power to meet the maker's rating and second, it is well known that an internal combustion motor of conventional type is most efficient in fuel consumption at 75-80 per cent of its capacity.

Tractors Conquer Colorado Desert

Farmers Convinced at Denver Demonstration That Machines Can Plow Virgin Land

DENVER, Col., June 13—Because of the tractor demonstration which has just closed here, it is believed that the work done in the 1200-acre sun-baked, virgin soil plain east of this city means the opening of 3,400,000 acres of such land to the tractors.

It has been a theory of the irrigated land farmer that the tractor was not suited to his work. He has pointed out that it often took 12 horses to draw a plow through this sort of earth, which never before was plowed. But he learned this week that the economic problem of plowing was the same, whether it was done by tractor or horse.

It is true that some of the smaller tractors did not run through this soil as they do the retilled soil in older country, but the fact remains that they did go through it. There was some backing and starting and heavy pulling, but in the end the soil was turned.

Almost every tractor maker in the country had a machine in this demonstration and most of them had all sizes. Also all kinds of implements and power utensils used on the farm were demonstrated. The mould board and the disk worked side by side. Reports are that in one or two instances the mould boards of the plows were ruined in a few hours' plowing. This may have been due to too fast plowing, for in many instances the mould board was functioning parallel with the disk plow. The disk reduces the draft in the very hard surface of sun-baked land, where the mould board plow leaves a glazed surface along the edge of the furrow.

The demonstration field was as dry as fields ever get outside a desert. The tractor has never figured prominently in the region where irrigation is needed to make farming possible, for reasons already stated. This demonstration has opened the eyes of the farmer to the possibility of big operations on this land.

There were farmers present from 15 States. The attendance was about 20,000 daily, and some days was estimated as high as 30,000. There are 4,000 tractors in use in Colorado. One revelation to many farmers was that the tractor would do all the work of the stationary engine, which represents heavy investments in this country because there is much need for power.

Manufacturers Learn Lessons

The manufacturer learned much. One thing was that too much must not be guaranteed for a tractor in this soil. It is a different proposition from that in older farming districts. He also learned that the big tractor, as a rule, was best suited for this job.

The demonstration was under the direction of the National Tractor Manufacturers' Association, aided by the Denver Civic and Commercial Association and the Denver Tractor Club.

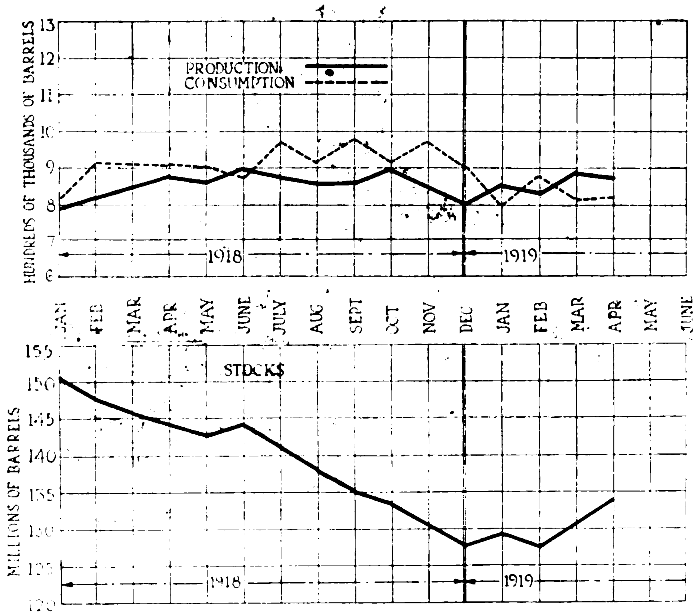
—

OIL PRODUCTION BULLETIN

WASHINGTON, June 13—A bulletin on the "Decline and Ultimate Production of Oil Wells with Notes on the Valuation of Oil Property," by Carl H. Beal, has just been issued by the Bureau of Mines, Department of the Interior, and and outlines methods for estimating the amount of oil that can be recovered from properties in the various oil fields of the U. S., and data on the application of these methods for the valuation of oil properties.

CRUDE PETROLEUM PRODUCTION IN EXCESS OF CONSUMPTION

WASHINGTON, June 12—The charts reproduced herewith show graphically the relatively great improvement in the crude petroleum position in comparison with that existing practically throughout 1918. During last year consumption was almost invariably in excess of production, the only exception being for a few days during the summer. This temporary gain was lost almost mmediately and the position became more unfavorable than before. Production is now well above consumption and stocks show a gratifying increase. Indications tend to show that the improvement is likely to be maintained.



Weird Cars Appear in Scandinavia

German War Loot Sold There—Skeleton Cars Offered on Long Credit

NEW YORK, June 17—Birger Jacobsson, who is in charge of automotive exports to Scandinavia for J. B. Crockett Co., has been in this country for two weeks seeking to expedite shipments of passenger cars. He says that his company has been unable to obtain all the cars needed for its trade, but that excellent truck deliveries are being made which are giving every satisfaction in the Scandinavian countries.

Scandinavia, according to Mr. Jacobsson, is practically a no man's land for the sale of cars, especially those coming from Germany.

"The Germans," he says, "are shipping some very strange cars into that country. Excellent Mercedes are arriving, with no tires and lacking decent paint and upholstering. While reports have it that there is rubber now in Germany, none is allowed for export. That country is still short of leather and textiles.

"These cars can be bought for 30,000 marks (about $2,000 at present value of the mark), but when the purchase is made the owner's troubles begin. He cannot buy tires to put on his car unless he disguises it. The Allies control the tires and they have a system of numbering that enables them to trace any tire found on a German car.

Rolls-Royce Cars Sold for $1,000

"Excellent Rolls-Royce and French cars are for sale in Scandinavia for $1,000 up, but they were all stolen from Belgium and France during the war. As soon as such a car is offered for export or is found outside Scandinavia by Allied officers, it is seized. The owners cannot buy supplies for these cars unless their origin is concealed.

"There are to-day some strange mixtures of equipment in the cars one sees in these countries. One finds Mercedes chassis with a Hall-Scott airplane engine installed. I have ridden in a Baby Peugeot equipped with a Ford engine.

"Strange engines of all makes are set in well known cars. Many of these engines were taken from captured airplanes and shipped abroad.

"The Germans are extending any credit desired on cars. They fear that money sent now will be taken away by the Allies."

Mr. Jacobsson returns to Scandinavia this week.

—

NEW PAINT MANUFACTURER

JACKSON, MICH., June 12—The Central City Paint Mfg. Co., with a capital stock of $300,000, has been formed here by John E. Van Horn. Mr. Van Horn started the Pontiac Mfg. Co. 16 years ago, disposing of this interest in 1918. The company will manufacture paint for the automotive industry.

Rules Governing National Tractor Demonstration at Wichita in July

Two Hours Are Allotted for the Public Exhibition—Land for Private Demonstrations Provided Daily—Draw for Positions on Opening Day

CHICAGO, June 16—The rules for the National Tractor Demonstration at Wichita have been drafted by the Tractor and Thresher Department of the National Implement & Vehicle Association. The rules are being demonstrated by the Chicago office of the Association. H. B. Dinneen, secretary of the Tractor Demonstration Committee, of Moline, Ill., is receiving entries. Other questions concerning the demonstration are being answered by A. E. Hildebrand, superintendent, at Bloomington, Ill.

The regional demonstration at Aberdeen, S. D., probably will be held the week of Aug. 18-23. No more regional demonstrations will be authorized. The rules for the Wichita demonstration follow:

1—Public demonstrations shall begin at 1 o'clock and end at 3, unless other hours are announced by the national demonstration committee at least 24 hr. before starting time. Private demonstrations may be held in the forenoon from 8 to 11:30 o'clock.

2—No exhibitor will be allowed more than one tractor of each size and type on the field during the public demonstration doing the same kind of work. He may have one or more machines performing different operations, namely: one plowing, one disking, one seeding, etc. Thursday morning from 9 to 11:30 will be devoted to seedbed preparation, seeding and cultivating.

3—Size of land for each tractor exhibitor for plowing demonstrations will be determined by the number of plow bottoms pulled, the width of plows and the highest plowing speed of tractor as given in entry blank. Each tractor exhibitor must plow out dead furrow to its left.

4—All exhibitors will be allotted land in the same field or adjoining field during each day's demonstration. Land for private demonstrations will be provided daily in one field or adjoining fields.

5—All plows on any given gang must be set at the same depth and kept there during the day's demonstration. This depth will be announced daily by general manager. Plows found operating otherwise will be ordered from the field for the balance of the day's work.

6—In all public demonstrations, the motor or tractor must not be run at more than 10 per cent above the highest speed of each as indicated in the entry.

7—Positions on field for each day will be arranged by lot in the following manner:

Separate drawings for each day's demonstration will take place at 10 a. m. Monday, the opening day of the demonstration. The drawings will be made from serial numbers representing total number of exhibitors.

Position on field for each public demonstration will be according to numbers, 1, 2, 3, 4, etc., as indicated by the drawing for that day.

The lowest number of land in each field shall be at point in field nearest general headquarters provided each exhibitor shall have all his land together.

Exhibitors who do not have representative at drawing will be represented by the general manager or someone appointed by him.

Each exhibitor will be required to finish his land daily in a workmanlike manner and assist in plowing the end lands as directed by the general manager.

8 Each field plowed will be surveyed and staked ready for afternoon demonstrations. These fields will be tested for the drawbar pull of a 14-in. plow, plowing at the depth specified previous to the demonstration. All manufacturers will be furnished information relative to drawbar pull so they can better determine the number of plows to use on each gang.

9—Each tractor shall bear a placard to be furnished by exhibitor, showing the brake horsepower of engine, the revolutions per minute, the plowing speed in miles per hour and the kind of fuel used and its Baume test. Tractors using more than 5 per cent of gasoline shall be classed as burning gasoline and be so placarded.

10—All tractors on the demonstration field belonging to one exhibitor must be kept on or along the land allotted him for that day's demonstration until the hour designated by management for returning to headquarters.

11—No machine will be allowed to operate with special equipment other than that designed for practical use with same. No spectacular methods will be permitted on the part of salesmen or others to attract crowds. The demonstration must speak for itself.

12—Each tractor exhibitor will have the privilege of burning any kind of fuel he desires, but no one will be permitted to burn fuel of a higher gravity test than that used by his competitor burning the same kind of fuel. All exhibitors will be required to obtain fuel from one source, such to be designated by general manager.

13—No time will be required of exhibitors to make moving pictures or group photographs for commercial purposes. Manufacturers can arrange to get photographs during the demonstration if they desire. Any manufacturer or representative of farm or trade papers or news agencies will be allowed to have their official photographer on the grounds to get pictures for their own use.

14—Manufacturers will be privileged to exhibit not more than one of a kind of belt-driven machines in connection with their exhibition.

15—The interpretation and enforcing of these rules shall be left to the national tractor farming demonstration committee and its general manager.

16—Each company exhibiting at these demonstrations shall appoint one manager who will be expected to report to the general manager not later than 8 o'clock each morning for instructions and information regarding the day's work. This manager of exhibits will be held accountable for the work of his company, and no instructions will be issued to anyone else, nor will requests, instructions or complaints be recognized from anyone but this exhibit manager. He shall wear a badge furnished him, specifying his being official exhibit manager.

17—Each exhibitor will be expected to keep plows, tractors, etc., around his tent arranged in first class order and the land allotted him for exhibiting purposes free from circulars, rubbish, etc., such as will be distributed around headquarters daily. They also will be expected to use care at all times in operating machinery with respect to its safety for all visitors. The management will appreciate co-operation of these exhibit managers in all matters.

18—Each entrant will sign the rules and thereby agree to live up to the rules and co-operate with the committee in every way to make the tractor demonstration a success.

19—The field manager shall have authority to order from the field any machine whose operator does not comply with the rules, and, further, any exhibitor who is manifestly disregarding the rules will not have land laid out or furnished for him on the succeeding days or until such time as he has met the condition.

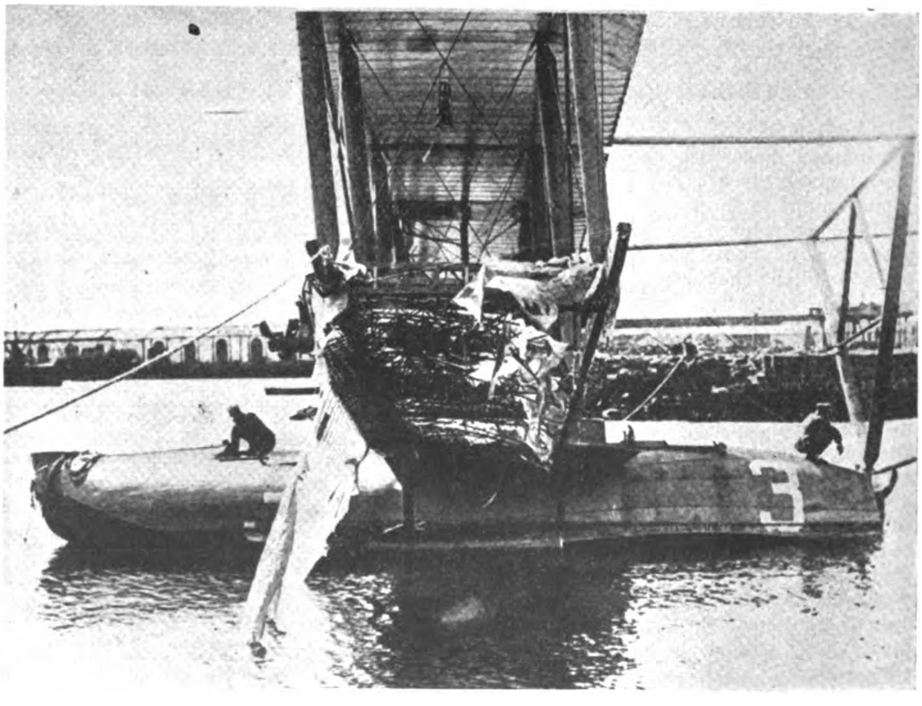
20—No exhibitor joining the national demonstration will be permitted to exhibit until he has given correctly the price that he is in position to furnish tractors at regular production, the correct weight of tractors and all data pertaining to their construction and rating, minimum and maximum, speed at which the motors are to run, the committee to have the right to have any such machines placed under test to prove the correctness of the data that is furnished.

21—No exhibitor shall have more than twenty-five tractors of all types and kinds on the demonstration grounds.

Each exhibitor who is a member of the National Implement & Vehicle Association shall pay $100 entry fee to participate in the National Tractor Farming Demonstration for 1919, and each non-member shall pay $200 entry fee for the same privilege. Remittance shall accompany entry application. Entry fees are to be used for defraying the expenses of the demonstration.

CARS AND TRUCKS FOR U. S.

WASHINGTON, June 14—The United States Indian warehouse at Chicago has asked for bids for 17 light weight touring cars and 7 motor trucks with light delivery bodies. Bids will be received either from manufacturers or regular dealers.



The NC-3 at Ponta Delgada, showing damage to wing. Official photo by U. S. Naval Air Service

REPUBLIC SURPLUS $900,770

NEW YORK, June 16—The Republic Motor Truck Co., Inc., reported to the Stock Exchange a surplus of $900,770, after the payment of interest and other charges and war taxes, in a statement summarizing its affairs for nine months ending March 31 last. Net sales aggregated $12,039,474, and costs reached $10,545,582, leaving net profits of $1,493,892. The profit and loss surplus was given as $5,765,848, all figures including the Republic Motor Truck Co. of California.

NAPOLEON MAKING CARS

TRAVERSE CITY, MICH., June 14—The Napoleon Motors Co., manufacturers of Napoleon trucks, has not gone out of the passenger car business as has been reported, but is diverting its production to a great extent to the manufacture of trucks.

NEMOURS TRADING CORP.

NEW YORK, June 14—The Nemours Trading Corp. has been formed with a capital of $12,000,000 to take over the Allied Industries Corp., French-American Constructive Corp. and the Merchant & Manufacturers Exchange, the last of which owns the Grand Central Palace, which is to be used as headquarters for the new corporation as soon as it is released by the Government. Associated with this corporation will be Bonright & Co., bankers.

The Nemours Trading Corp. is incorporated as domestic and foreign manufacturers' representatives and general shipping merchants. They are exclusive sales representatives of Wondermist polish, made by the Wondermist Mfg. Co., Boston, Mass.; Woodworth tire and bead spreaders, made by the Allied Industries Corp.; King crank holder and McCulloch timer, made by the A. P. McCulloch Machine Co., Boston, Mass. Other items will be added to the line from time to time. The officers are: President, Alfred I. du Pont; vice-president and general manager, J. N. Nixon; vice-presidents, L. P. Lawrence and R. H. Michels; and secretary-treasurer, G. W. Fay.

Blood & Wright, who specialize in automotive service at Detroit, have been appointed exclusive representatives in Michigan for the Nemours Trading Corp. and are also Michigan representatives for the K. & S. lock. They are opening a sales and installation store in Detroit for lock business exclusively.

COMPLAINT AGAINST TONKHEIM

FORT WAYNE, IND., June 13—Complaint against the Tonkheim Oil Tank & Pump Co., manufacturers of automatic measuring oil pumps, has been made by the Federal Trade Commission, charging that this concern systematically entices the employees of its competitors "with the purpose of annoying, embarrassing and obstructing them in their business." The company was cited to appear before a commission in Washington, July 22.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

934 FORDSON SALES IN MAY

NEW YORK, June 14—Continued heavy rains interfered with tractor sales during April, according to C. L. Herring, president of the Herring Motor Co., handling Fordson tractors in Iowa, Nebraska and South Dakota. Fordson sales in this territory for May totaled 934, as compared with 1340 in April. As May is not considered a tractor selling month it would scarcely be correct to infer that tractor sales have been slow this year.

There are approximately as many Fordsons sold in Iowa as in Nebraska and South Dakota combined. The sales in Nebraska are approximately double those in South Dakota. On this basis 156 were sold in South Dakota, 312 in Nebraska and approximately 476 in Iowa.

MOLINE PLOW FOUNDRY

MOLINE, ILL., June 17—The Moline Plow Co. is building a foundry at East Moline to cost $275,000. The contract calls for the completion of the structure by Oct. 15. The building will be 2 stories, 120 by 380, of reinforced concrete and steel. Tractor and agricultural implement castings will be produced at the new plant.

NEW CAR AND TRACTOR

PHILADELPHIA, June 17—The L. M. Heifner Manufacturing Co., with L. M. Heifner at the head, is being formed with a capital of $1,500,000, to manufacture cars and tractors. An option dating from July 1 has been taken on a building in Chester, Pa., having 100,000 sq. ft. of floor space, and operations are expected to begin by August 15. The tractor to be made will be composed of standard units, especially suitable for small farms, and will cost $1000. It will be designed to be used with a 2-bottom plow, having a clearance of 27 inches. Production of 3000 the first year is the goal.

All types of passenger cars are planned, having the following specifications: aluminum body, Continental Red Seal engine, 128-in. wheelbase, Bosch magneto, Brown-Lipe transmission, Borg & Beck clutch, Spicer universals, Timken axles, Parish & Bingham Co. frame, Perfection springs, Stewart vacuum feed, Fedders radiator, Delco starting and lighting system. The color will be optional.

The Smith-Davis Machinery Co., Market and 21st streets, of which Mr. Heifner is general manager, will represent the new line in Eastern Pennsylvania, New Jersey, Delaware, and part of Maryland.

BUILDING CANADIAN PLANT

OSHAWA, ONT., June 14—General Motors of Canada, Ltd., as planned, is erecting a 60 x 160 ft. plant at Walkerville, where engines, transmissions and all heavy parts of cars used in the Oshawa assembling plants will be manufactured. These operations are going ahead rapidly. For the time being motors, transmission, etc., for McLaughlin cars, Chevrolet cars and trucks and Oldsmobile cars and trucks will be made in Walkerville. Castings, engines and transmissions for Samson tractors and G.M.C. trucks will also be turned out.

In Oshawa, where McLaughlin and Chevrolet cars are now made, a 400 x 80 ft. 4-story building will be erected to assemble Oldsmobiles and trucks. It is planned to start production this fall.

In addition to this plant it has been decided to erect a central shipping building, 200 x 80 ft. In conjunction with this central shipping station there will be a large storage building with a capacity of 1000 cars. This building will be 4 stories, 400 x 80. An enameling plant to be erected will be 3 stories, 300 x 80 ft.

In addition there will be alterations in the present plant equipment of the General Motors unit at Oshawa. The south building, now used for Chevrolet parts and ge... storage, will be converted into a manufacturing plant t produce the Baby Grand Chevrole model.

The ground under the present 490-ft Chevrolet assembling plant will be excavated and a basement put under the entire space, thus adding one complete story.

All buildings are of steel and concrete.

G.M.C. CAPITAL $1,020,000,000

NEW YORK, June 16—Increase of the capital stock of the General Motors Corp. from $370,000,000 to $1,020,000,000 was voted at a stockholders meeting at Wilmington, Del., June 12. The stock division calls for $20,000,000 preferred, $500,000,000 debenture and $500,000,000 common shares.

The increase, according to John J. Rashob, director of the corporation, is intended to enable the company to take advantage of any opportunity that may develop in the motor field, extensions of plants being financed out of earnings rather than stock sale proceeds.

Reports that the enlarged capitalization would provide funds for absorption of the Ford Motor Co. were denied.

ACME TRUCK PRICES ADVANCE

CADILLAC, MICH., June 16—The Acme Motor Truck Co. will raise the price of its 3½- and its 5-ton models $100 each, effective July 1. The following is the new price schedule:

Capacity	New Price	Old Price
1-ton	$1,950	$1,950
2-ton	2,750	2,750
3½-ton	3,750	3,650
5-ton	4,850	4,750

Fisher Body Corp. Earns $1,603,289

DETROIT, June 16—The Fisher Body Corp. and its subsidiary, the Fisher Body Corp. of Canada, earned $1,603,289 last year after deducting interest, federal taxes and appropriation for dividends on the company's outstanding preferred stock. This earning is equivalent to $6.44 a share on the company's 200,000 shares of common stock of non par value.

Before deducting the federal tax, but deducting all expenses of the business, including expenditures for repairs, maintenance of the properties and an adequate allowance for accruing renewals and depreciation, the net earnings were $3,534,853.38. Interest deductions were $306,564.08 and the amount set apart for federal income and war excess profit taxes was $1,625,000.

The consolidated balance sheet lists assets aggregating $20,352,001 on April 30, 1919, with current assets of $12,889,541.37, and current liabilities of $8,635,265.76, indicating net working capital of $4,254,275.61. Investment in plant and properties after writing off $864,687.10 for depreciation and including $250,000 as the value of patents, was $320,813.97. Sinking fund assets for redemption of preferred stock amounted to $60,054.55 and deferred charges were $81,591.21.

Current assets comprise inventories of raw material work in progress and supplies appraised at $6,693,044.70, accounts receivable $2,589,092.54, investment in Liberty bonds at par $1,500,000 and cash $2,107,404.13.

Current liabilities include bank loans aggregating $4,065,000, of which $1,475,000 was for the purchase of Liberty bonds; accounts payable, $1,429,579.19, a balance of $251,503.31 due the U. S. government on airplane contracts, accrued salaries and payrolls $822,190.35, accrued interest $7,007.19, and provision for Federal taxes and Canadian business profits war tax, $2,059,985.72.

Capital liability was $6,445,324.98, consisting of $6,000,000 authorized 7 per cent cumulative preferred stock, of which $5,000,000 was issued and $666,000 retired, leaving $4,344,000 outstanding and 200,000 shares of common stock of no par value, which is given a book valuation of $2,111,324.98.

From surplus of $4,309,568.32 on May 1, 1918, there was deducted $403,000 additional provision for federal taxes of 1918. The balance was increased by $1,298,750.40, the part of the year's net earnings remaining after appropriating $304,538.80 for payment of preferred stock dividends, also by $66,091.66, the surplus arising from the retirement of preferred stock at a discount, making total accumulated surplus $5,271,400.36, on April 30, 1919.

CHIEF MOTORS ISSUES STOCK

PORT HURON, MICH., June 12—The Chief Motors Corp. has placed on sale 20,000 shares of 8 per cent participating preferred stock and 20,000 shares of common stock. The par value of both stocks is $10. According to the sales plan, one share of preferred and one share of common is selling for $12.50.

The company is raising additional capital to increase its production so that enough engines may be produced to fill orders already received. The Chief Motors Corp. builds a kerosene-burning tractor engine, and has assets totaling approximately $400,000, not including good-will, organization and other tangible assets.

John Erd, formerly of the Erd Motor Corp., Saginaw, Mich., is president and general manager of the Chief Motors Corp. The corporation has opened sales offices in Detroit.

HOLT COMPLETING PLANT

PEORIA, ILL., June 17—Orders were received this month to complete the addition to the Holt Caterpillar tractor plant at East Peoria, Ill. The buildings were partially finished when peace was declared and the work of construction has since been halted. It will require $1,000,000 to complete the plant according to the original plans. Capt. J. E. Hopkinson, of the regular army, will be assigned to duty at the Holt works and supervise the expenditure of the additional sum. The total cost of the plant will be $3,000,000.

TIRE PLANT FOR WARREN

WARREN, OHIO, June 17—Construction will commence immediately on the D. & M. Cord Tire Co., Cleveland, rubber plant here, to cost $2,500,000. The company was recently organized, with Walter D. Myers, attorney and banker, of Cleveland, president, and Walter R. Denman, secretary and general manager.

The plant here will manufacture cord tires, inner tubes and accessories. It will start with a single unit employing 500 and turning out 1000 tires a day. Eventually it will consist of three units with a daily capacity of 4,000.

WALLIS TRACTOR RESUMES

RACINE, WIS., June 12—The Wallis Tractor Co. resumed operations June 2 with a large force and on a greatly increased production schedule, after being closed down for a month, during which time the entire plant was overhauled. The Wallis company from now on is operating on an 8-hour-day basis, without overtime. Rates have been established which take into consideration present living conditions, and the voluntary proposition is meeting with the approval of all employees.

MACHINE SHOP FOR KALAMAZOO

KALAMAZOO, Mich., June 16—The Kalamazoo Motors Corp. is erecting a 1-story machine shop covering about 2000 sq. ft. A covered loading and unloading platform is included. Plans also provide for a building for the stock room. These changes will double the capacity of the present plant and permit the assembling of 125 to 150 trucks a month.

Army Trucks Cross Country

WASHINGTON, June 16—The first transcontinental trip of an army motor truck train will start from Washington, July 7, under direction of the Motor Transport Corps, and end at San Francisco within two months. Before the trucks start on this journey, which is intended to provide tests of the standard motorized army equipment, demonstrate long distance motor post and commercial transportation, and provide for other studies and training, President Wilson will dedicate a milestone in front of the White House to represent the starting point for highways radiating out of Washington. The train will follow the Lincoln Highway as far as possible. It will comprise two complete motor transport corps companies, include 5 passenger cars, 35 trucks of all army types, 2 ambulances, 6 motorcycles, 2 tank trucks, 2 kitchen trailers, 2 water tank trucks, 1 engineer shop truck and 1 searchlight truck.

Technical personnel from the motor transport corps, engineer corps, medical corps, field artillery and air service will make the journey.

ARMY EQUIPMENT FOR HIGHWAYS

WASHINGTON, June 14—The Department of Agriculture will receive tractors, road rollers and other highway building equipment from the American Expeditionary Force as quickly as it can be returned. The War Department has ordered shipment of this machinery from France at the request of the Department of Agriculture, which will use it in the construction and maintenance of federal highways. The equipment will be distributed to the states without charge, and apportioned together with the 27,000 army trucks which are being distributed by the Bureau of Public Roads at the request of the State Highway Department.

The equipment being returned from France includes 1500 tractors, 400 road rollers, steam and gas driven, concrete mixers, graders, rock crushers, electric motors, industrial locomotives, dump cars and quantities of smaller equipment.

TRANSPORTATION NEEDS

WASHINGTON, June 14—The Highway Transport Committee of the Council of National Defense has requested the assistance of congressmen in determining the necessary routes for the operation of rural motor express. In a letter addressed to members of Congress, the committee points out the need for every form of transportation at this time, and numerous examples of districts in which the transportation facilities are inadequate.

In various southern districts, it is stated, hundreds of bales of cotton are lying on the ground without cover because of lack of transportation, while in the Northwest millions of bushels of grain lack transportation to move them.

UNIVERSAL AVIATION CO. FORMED

DETROIT, June 14—The Universal Aviation Co. has been incorporated here for passenger service between Detroit and Cleveland, and to afford the public opportunity for pleasure trips in Michigan, Ohio and Indiana.

The officers and backers of the new enterprise are: President, Henry M. Leland, president of the Lincoln Motors Co.; first vice-president, E. E. Allyne, president of the Aluminum Castings Co., Cleveland; second vice-president, David Pell, director of the Hayes Mfg. Co., Detroit; secretary and treasurer, Harry D. McCullough, secretary and treasurer of the King Motor Car Co.; general manager, J. T. Patterson, Detroit; C. W. Leland and Le Roi J. Williams of the Lincoln Motors Co.; Frank P. Book of the Book estate; J. W. Murray, president of the J. W. Murray Mfg. Co.; Hal Smith of the Hayes Mfg. Co.; C. H. Haberkorn of the Haberkorn Furniture Co.; George D. Wetherbee, Thad Leland, Harold Armstrong, C. R. Short, chief engineer of the Northway Motors Co.; Clarence Chandler, B. F. Bertram and Messrs. Ryan and Sweeney of the Allyne-Ryan Co., Cleveland, and Harry D. Mills of Ann Arbor.

Land flying activities will begin immediately at Morrow Field, with four airplanes of the Curtiss type. Six more machines have been ordered. The company has two flying boats, which will land at the foot of Townsend Avenue. The pilots, all of whom have been in Government service, are S. H. Dicran, Edward Wismiller, C. R. Sinclair and C. R. Griffin.

$5,000,000 HOUSING CONCERN

DETROIT, June 12—Eugene W. Lewis, former vice-president of the Timken-Detroit Axle Co., and a director of the First & Old Detroit National Bank, has been elected president and general manager of the newly organized $5,000,000 house financing corporation of Detroit. This company, organized by leading bankers and manufacturers, aims to solve Detroit's serious housing situation, and incorporation papers will be filed at Lansing within a few days. Up to the present time Detroit has had no organization with facilities for transacting and disposing of all features of the problem of financing and building of homes. It aims to give the man with a few hundred dollars with which to start a home an opportunity to build on the easy-payment plan. It is estimated that Detroit has a shortage of approximately 60,000 homes.

On the board of directors are many men well known in the automotive field, including Frank L. Klingensmith, vice-president of the Ford Motor Co.; Alvin Macauley, president Packard Motor Car Co.; H. W. Alden, vice-president Timken-Detroit Axle Co.; D. A. Brown, president General Necessities; James Inglis, president American Blower Co.; R. B. Jackson, general manager Hudson Motor Car Co.; A. L. McMeans, secretary Dodge Brothers; A. W. and John R. Russel of the Russel Motor Axle Co.; James T. Whitehead of Whitehead & Kales Iron Works.

Housing Situation in Industry Still Critical

BATTLE CREEK. MICH., June 14—Five hundred new homes are needed here immediately to care for the increased population. The Chamber of Commerce is securing bids upon the construction of four different types of houses. The banks and private loan associations are co-operating by loaning money for home building on an easy payment plan. At the present time the manufacturing companies are not actively engaged in relieving the situation, but plans are under way which will result in the manufacturers building houses for their own employees.

PORT HURON NEEDS HOMES

PORT HURON, MICH., June 14—There is a shortage of from 300 to 400 homes here. The Chamber of Commerce is endeavoring to form an organization for the purpose of building 200 small homes for foundry employees. Several of the large manufacturing companies are also contemplating building homes for their workers. The building and loan associations and the banks are aiding in this campaign and a great number of individual parties have been financed.

Over $3,000,000 has been expended in additions to industrial plants. Upwards of 8000 persons have been added to the population in the last 2 years, with less than 300 homes constructed. The general demand is for homes renting from $15 to $25. It is estimated that 82 per cent of the men employed in industries own their own homes.

MORE HOUSES FOR SAGINAW

SAGINAW, MICH., June 14—Saginaw is responding to the demand for more houses for hundreds of families brought here by new and growing industries. During May 83 building permits were issued, besides three for factories. The total cost was $467,157.

JACKSON BUILDING HOMES

JACKSON, MICH., June 14—To relieve the serious shortage of homes here, the Jackson Co-operative Realty Co. is about to incorporate for $200,000, its mission being to build homes for workingmen. This company has been organized for several months and has already built 45 houses.

HOMES FOR PORT HURON

PORT HURON, MICH., June 14—The organization of a home building corporation capitalized at $1,000,000 is the plan proposed for the relief of the serious housing situation here.

The company will buy vacant lots and build houses where prospective purchasers desire, and will sell on the installment plan with easy payments. The sale will be at cost of lot and building plus 15 per cent, and if the purchaser keeps up the payments for 5 years the profit will be reduced.

500 HOMES NEEDED IN ANN ARBOR

ANN ARBOR, MICH., June 14—According to real estate dealers the city needs at least 500 homes. It is thought that the manufacturing interests will attempt to formulate a relief plan, inasmuch as they are all in need of men, whom they are unable to obtain because of dwelling shortage.

BAY CITY, MICH., June 14—This city proposes to build 800 new homes this year. The Chamber of Commerce is drafting plans to provide homes. It is asking its members each to build from 1 to 50 modern homes to sell on monthly payments at 6 per cent interest. A number of wealthy citizens' associations, etc., have agreed to this and a complete building program will be drawn up.

KALAMAZOO, MICH., June 14—Kalamazoo expects the housing situation to greatly improve within the next 30 days. There is a big shortage of houses here. The Chamber of Commerce has organized a committee and it is estimated that between 300 and 500 new dwellings will be put up.

AKRON ADDS DWELLINGS

AKRON, June 14—The Akron Home Owners' Investment Co. will start work in 10 days building 5000 homes at a cost of $25,000,000. All homes will be completed before the end of the year. This association was recently organized to care for the critical housing situation here. In addition to the building work the company will make loans to those who wish to build their own homes, on an easy payment plan. The cost of the houses to be erected will average $5,000 each. The work of the association will not conflict with that of the various industrial plants which are planning house-building campaigns of their own. It is estimated that by the end of the year Akron will have 9000 new dwellings.

The Coventry Land Co. has issued contracts for the construction of 100 houses to cost approximately $500,000. They are to be built in the Firestone park.

NEW DETROIT HOUSING CORP.

DETROIT, June 14—A new house-building corporation, the Banker's Land & Investment Corp., capitalized at $1,000,000, is preparing to aid Detroit in solving the critical housing situation. The company has opened offices and construction work will start at once. Within 12 months the corporation hopes to provide housing accommodations for at least 3,000. This concern is a merger of six operating subdivision and building companies controlled by Frederick H. Zeigen.

The officers of the corporation are: president and general manager, F. H. Zeigen; vice-president, Clarence E. Wilcox, Detroit corporation counsel; secretary, Leslie B. Robertson, former head of the Ford Motor Co. legal department; treasurer, Richard D. Cudmore, cashier of the People's State Bank. Cass Zeigen, former assistant auditor of Maxwell-Chalmers, is auditor.

Calendar

SHOWS

Aug. 30-Sept. 6—Minnesota. State Fair.

Sept. 1-6 — Indianapolis, Ind. State Fair, Cars and Accessories, Indianapolis Automobile Trade Assn., John B. Orman, Manager.

Sept. 13-20—Cincinnati, O. Ninth Annual, Music Hall, Cincinnati Automobile Dealers' Assn., H. K. Shockley, Manager.

Sept. 15-20 — Springfield, Mass. Eastern States Exposition.

*Oct. 9-19—Paris. Grand Palais. International Automobile Mfrs. Congress.

Nov. 7-16—London. Olympia Motor Car Exhibition—Society of Motor Mfrs. and Trades.

December — Brussels. International Automobile Mfrs. Congress.

Jan. 3-10 — New York, N. Y. Grand Central Palace, National Automobile Chamber of Commerce, S. A. Miles, Manager.

Jan. 24-31—Chicago, Ill. Coliseum, Cars; Drexel Pavilion, Trucks; National Automobile Chamber of Commerce, S. A. Miles, Manager.

January — New York. International Automobile Mfrs. Congress.

February — Chicago. International Automobile Mfrs. Congress.

Feb. 23-Mar. 6 — Birmingham, Eng. British Industries Fair.

TRACTOR SHOWS

July 14-19—Wichita, Kan. Automotive Committee of National Implement Assn.

July 28-29—Columbus, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 1-2 — Piqua, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 18-22—Aberdeen, S. D. Sectional Tractor Demonstrations.

October—Ottawa, Ont., Can. Interprovincial Plowing Match and Tractor Demonstration.

CONTESTS

July 4—Hohokus, N. J. Dirt Track Event.

July 4—Tacoma, Wash. Annual speedway races.

July 4—Atlantic City, N. J.—Airplane races—Aeronautic Convention.

*July 19—Uniontown, Pa. Speedway race.

*July 26—Sheepshead Bay, L. I. Speedway race.

*Aug. 15 — Middletown, N. Y. Dirt track event.

*Aug. 22-23—Elgin, Ill. Road race.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Sept. 27—Allentown, Pa. Dirt track event.

*Oct. 1—Cincinnati, O. Speedway race.

*Oct. 4—Trenton, N. J. Dirt track event.

*Oct. 11—Danbury, Conn. Dirt track event.

*Tentative dates.
†Sanctioned.

CONVENTIONS

June 16-19—Detroit. American Society of Mechanical Engineers spring meeting, Hotel Statler.

June 23-28—Ottawa Beach, Mich. S. A. E. Mid-summer Meeting.

July 9-10—Buffalo. Motor and Accessory Mfrs. Assn. Mid-summer convention.

Sept. 22-24—Philadelphia. Annual Convention, National Association of Purchasing Agents. Bellevue - Stratford.

May 12-15, 1920—San Francisco. Seventh National Foreign Trade Convention.

January — Washington. Pan American conference.

De Palma in Packard Victor on Sheepshead Speedway

SHEEPSHEAD BAY SPEEDWAY, N. Y., June 14—Ralph De Palma, driving a 12-cylinder Packard, won the International Sweepstakes here to-day, covering the 50-mile course in 26:23:4, and establishing a new record for the track of 113.76 m.p.h. Ralph Mulford, in a 4-cylinder Frontenac, and Tom Milton, in a 4-cylinder Duesenberg, made local records in the 30 and 10-mile events, their times being, respectively, 16:01:20 and 5:20:20. Mulford also carried off the honors in the special 10-mile race.

Dave Lewis came in second and Joseph Boyer, Jr., third in the 50-mile event. Ralph Mulford was in second place and De Palma in third in the first race, a 10-mile event, which Tom Milton won. De Palma made second place and Joseph Boyer, Jr., again third in the 30-mile run, and in the special 10-mile event, which was won by Mulford; Joseph Boyer was second and Ralph De Palma third.

The winning Packard, equipped with a 24-valve engine with cylinders cast in threes, has a total piston displacement of 299.2 cu. in. The bore and stroke of the engine are 2 21-32 and 4½ in., respectively. The valves are located in the head, the pistons are of aluminum and there are two camshafts. The car has a 112-in. wheelbase and is equipped with the Delco ignition system.

The Frontenac, driven by a 16-valve engine of 3.87 in. bore and 6 in. stroke, has a 282.3 cu. in. piston displacement. The cylinders are cast in block, with valves in the head. The engine has a single camshaft, aluminum pistons, cone clutch and Bosch magneto. Its wheelbase in 110 in.

The Duesenberg also is equipped with a 16-valve engine, having the valves located in the head. The bore is 3¾ in., strokes, 6¾ in. and the piston displacement is 298.2 cu. in. It has two camshafts. The pistons are of Levett metal. Its other features include a cone clutch and Bosch magneto. The wheelbase is 116 in.

126,136 Motor Vehicles Held by A. E. F. According to Classified Inventory in Hanch Report of Trip Abroad

NEW YORK, June 16—A total of 126,136 motor vehicles, trailers and bicycles was in the hands of the A. E. F. in France, according to an analysis given by C. C. Hanch in his report to the National Automobile Chamber of Commerce recently. The report says that of this number, 7,368 were of foreign make, representing our purchases in Europe, practically one-half of which are motor trucks. We purchased 2,603 3 and 4-ton trucks from European makers.

The recapitulation is:

Type	American	Foreign	Total
Passenger cars	9,091	718	9,809
Light deliveries	10,110	41	10,151
½ and 2-ton trucks	12,651	681	13,332
3 and 4-ton trucks	19,285	2,603	21,888
5-ton trucks and over	2,696	78	2,774
Motorcycles	21,597	1,195	22,792
Ambulances	7,080	9	7,089
Tractors	144	125	269
Caterpillars	1,721	....	1,722
Trailers	3,745	1,552	5,297
Machine shop and repair trucks	1,575	16	1,591
Kitchen trailers	352	33	385
Omnibuses	14	3	17
Winch trucks	....	69	69
Reconnaissance cars	745	...	745
Fire engine and disinfectors	20	27	47
Laboratories	86	52	138
Machine shop trailers	94	15	109
Tank trucks	869	151	1,020
Anti-aircraft	20	....	20
Miscellaneous trucks	5	....	5
Bicycles	26,867	....	26,867
Total	118,768	7,368	126,136

GEORGIA DEALERS ORGANIZE

MACON, GA., June 14—Automotive dealers of this state have condemned a proposed bill to be introduced in the next legislature to assess truck license fees as high as $1,000 and $1,500 on trucks of 5- and 7-ton capacity. They are also against the Federal practice of confiscating cars carrying liquor. In order to handle these and other problems the Georgia Automotive Dealers' Association has been formed with about 200 members. R. C. Dunlap of this city is president. Harry C. Moock, St. Louis, business manager of the National Automobile Dealers' Association, spoke at the organization meeting.

S. A. E. SUMMER MEETING

Lighter Cars; Smaller Engines

S. A. E. Speakers Agree as to the Tendency of Design of Automobiles but Vary Many Pounds as to Their Ideas of the Net Result —Changes Favor the Car Owner

900-Pound Five-Passenger Car Is Seen as a Possibility

OTTAWA BEACH, Mich., June 25.

LIGHTER cars, with correspondingly smaller engines and with a trend toward closed bodies, are probabilities of the future in passenger automobile design, in the belief of experts who to-day contributed a symposium of papers to the summer meeting of the Society of Automotive Engineers.

The discussion dwelt also upon the necessity of mechanism designing intended to reduce fuel consumption and to permit utilization of lower grade fuels, economies to be enforced by the country's failing gasoline supply.

The papers forecast the passing of the 8 and 12-cylinder engine, except in occasional construction, holding up as the future standard the 6-cylinder motor for the larger cars and the 4-cylinder for the smaller types.

While foregoing an actual prediction, William B. Stout, consulting engineer of the United Aircraft Engineering Corp., declared it should be possible to build a 5-passenger closed car of present-day performance standard with a weight of 900 lb. Engineering and construction lessons taught by the war, he asserted, had laid the foundation for such an accomplishment.

Herbert C. Snow, engineer of the Winton Co., expressed the belief that the weight of the 7-passenger touring vehicle would be reduced to 3500 or 4000 lb. Resorting on a large scale to the use of alloy steels and aluminum alloy, he forecast, as well, that 5-passenger cars would be brought down to 2500 to 3500 lb., and the smaller machines to 1500 to 2500.

Improvement in car quality, both in design and workmanship, was anticipated by Henry M. Crane, vice-president and chief engineer of the Wright-Martin Aircraft Corp., in a paper which conceded a popular movement toward the closed car, in itself a factor opposing decreased weight. There was a growing demand, in Mr. Crane's opinion, for greater comfort in riding and a nearer approach to noiselessness in the operation of cars, conditions which would call into play the best in creative genius.

Mr. Stout on the 900-Lb. Car

The 900-lb., 5-passenger car, Mr. Stout contended, "should give 30 to 40 miles on a gallon of fuel and 10,000 to 15,000 miles on a set of tires. In riding ease it should surpass anything in heavyweight construction.

THE FUTURE CAR
WILLIAM B. STOUT

We should have a 900-pound, 5-passenger car that will be a better riding car than any now on the market. This will be made possible through war experiments for airplane construction. The body will be of plywood and the engine of 15-horsepower, 6-cylinder, weight 120 pounds. This car should give 30 to 40 miles on a gallon of fuel. The problems are in unsprung weight and axles and drives.

In cost, it should be built for no more money than cars of to-day of equal passenger capacity and performance. The care required to keep the car in shape should be far less than in present construction, and all parts could be oiled from the engine. Freedom from noise and rattles would be a feature, and the life of the car in proportion to its price much increased."

Engines could undergo a real revolution, not only in performance but in design, Mr. Crane stated, adding that a movement toward air cooling was likely, "as it is now possible to build air-cooled engines with a mean effective pressure as high as the best motor-car engines and cool them under motor-car conditions."

He continued:

"A car of 900 lb. weight—and this would mean a revision of some of our suspension ideas to entirely new fundamentals—would need but a good 15-hp. engine and other parts in proportion. This engine, being small, could call to itself the very best workmanship and material, and would not be a success unless it did.

"By the use of many small cylinders, not less than six, and some of the constructional and cooling ideas that have been proved during the war, this powerplant could be laid out as a real thermal job, with no cooling difficulties, and with wonderful economy. It would, of necessity, be radically different from the present-day air cooling to obtain the mean effective pressure desired. Its weight complete need not be over 8 lb. per hp., or 120 lb. for the complete engine with starting equipment. It should turn up to 2600 r.p.m. without undue vibration or power loss. Its cost per pound need not be over twice that of present engines in equal quantities. Since the motor car has become for us an all-the-year proposition there is more reason than ever for eliminating the radiator and its recurrent winter troubles. With the low total weight of the car and the small-bore engine, fuel economy would be far beyond present types."

Mr. Stout looked for wider employment of wood in passenger-car manufacture, declaring that in the production of airplanes for war "we found for the first time what wood was and how to use it, both for strength and for production. We found that wood, combined with the new waterproof glues into multiple units, as a dependable basis of structure under all weather conditions and under severe vibrations and stresses. We found that we could mold it, press it, cut it, and form it in a real production way, and obtain structures with a fraction of the weight for the same strength that was possible with steel. Of course, it had to conform to certain rules of structure, just as steel does, but the result has been proved, and the comparatively low production cost of plywood parts demonstrated. A 5-passenger body on a moderate wheelbase car, without glass, need not weigh over 200 lb., and still be a more permanent structure than a steel-wood combination."

On the question of comfort he said:

"To obtain riding ease the problem of unsprung weight would have to be studied all over again, and many ideas on axles and drive revised to new bases. The load of five passengers being such a large proportion of the total weight, some special type of suspension would become a necessity in the car outlined to obtain easy riding, whether full or part load were on board.

"As to cost of manufacture, this can be figured on a per pound basis, and would allow of higher-class work and materials without increasing the final cost of the car. Because of the lightness and small size of the power and transmission units, great accessibility could be had, while the car of the future, too, should be designed primarily with the owner in mind rather than the factory. This means a car that can be taken care of by the owner, with small outlay of effort or skill and infrequent oiling; a car with no grease cups or unlubricated joints, and an outside design such that a minimum of washing will keep it clean. This refers primarily to wheels, the hardest part of a car to keep looking right. For this reason alone the newer disk wheels have great possibilities.

"The motor car to-day, in its present form, has probably reached a maximum of performance. If we would obtain a radical economy or sales basis or performance, we must look to radical but balanced ideas. We must all admit that the car of to-day is still crude, and even though our shops at present are full of work and our desks of orders, we should remember that the firms which undertake research have always been the leaders, looking ahead, not only toward better engineering for its own sake, but that the per car cost of sales effort may be minimized and the line of sales convincement be more direct."

Mr. Snow for Reliability

In his paper, Mr. Snow regarded reliability, good performance and good appearance salient requisites of a good passenger car.

"In considering reliability," he said, "more attention will be paid to the automatic lubrication of every moving part throughout the chassis with minimum trouble to the owner. Parts which require attention will be made more accessible, minimizing the effort required to keep the car at its best, and enabling worn parts to be replaced more readily. More owners nowadays drive their cars than in the past, and the maintenance of these cars should be as simple as possible. The take-up points for the various adjustments should be located so that they can be reached with ease.

Limit of Acceleration Reached

"In the past 3 or 4 yr. a considerable improvement has been made in the high-gear performance of passenger cars. Acceleration and hill-climbing ability has been increased to a point which might well be considered a maximum for practical service. A car acceleration of from $3\frac{3}{4}$ to 4 ft. per sec. on direct drive, at speeds of from 5 to 25 miles per hr., with two or three passengers, should be ample. This is equivalent to climbing an $11\frac{1}{2}$ to $12\frac{1}{2}$ per cent grade at a constant speed between 5 and 25 miles per hr. On a lesser grade the car would have surplus power for acceleration. In addition to this low-speed performance a high-grade touring car should be capable of a maximum speed of 60 to 65 miles per hr. The number of miles per gallon of fuel should also be a factor in the performance of the car.

"In designing a car to give this performance, the total

weight of the car is a large factor. The weight of the car in turn is partly dependent on the size and carrying capacity of the body. The present seven-passenger body of a high-grade car is as large and roomy as could be desired, and there should be no need for further increase in size on future cars. This being the case, I believe that the total weight of the large seven-passenger car will be reduced to a point between 3500 and 4000 lb. To make this reduction in weight without any sacrifice in durability means the greater use of alloy steels as well as an increased amount of aluminum alloys. The medium size five-passenger car will weigh between 2500 and 3500 lb., and the small car between 1500 and 2500 lb.

Number of Engine Cylinders

"The size of engine which will give the desired performance to a car of given weight is dependent on the gear ratio and diameter of wheels; or, in other words, the engine revolutions per mile. If a low gear ratio is used, a smaller engine can give the same performance as a large engine with a higher gear ratio. However, the use of the low gear ratio requires a very high engine speed to obtain maximum car speed, and the power may drop off so much at these high engine speeds as to be insufficient to propel the car at the maximum speed desired. In this case it is necessary either to raise the gear ratio and sacrifice the low-speed performance, or to reduce the maximum car speed. By using a transmission with direct drive on the third speed and a geared-up drive on the fourth it is possible still to retain the low axle ratio and have good low-speed performance on direct drive and at the same time to have a higher maximum car speed available on the fourth gear. The objection to this type of drive has been the noise of the fourth-speed gears. I believe that in the future this type of drive will gain in popularity. It is possible that the silent chain will be used in the transmission with considerable advantage in providing a quiet drive for the top speed.

"I believe that the engine for the large car weighing 3500 to 4000 lb. will have a total displacement of between 300 and 400 cu. in. The largest percentage of these engines will undoubtedly have six cylinders. Cars of this class require the best that can be obtained in smooth running and perfect balance. The six-cylinder engine fills this requirement. It also gives good fuel economy and can be made very accessible. In the medium weight class I believe that this type of engine will predominate, but not to quite as great an extent as in the 3500 to 4000 lb. class. The remainder of these cars will be equipped with four-cylinder engines for the most part, as I doubt very much whether there will be many eight or twelve-cylinder engines in cars under 3000 lb. in weight. In the lightweight class I believe that it will be about an even break between four and six cylinder engines.

"Taking up the design of the engine, we can look for the greatest improvement to be made in the cylinders, valve ports, valve mechanisms, manifolds and carbureters. With the fuels growing poorer all the time, the manifolds must be designed to give better distribution, and more heat must be applied to the manifolds to vaporize the liquid fuel on the walls at the lower speeds. To maintain good torque at high speeds the resistance in the manifold, valve ports and in the cylinder around the valves must be kept as low as possible. At the same time the size of these passages should not be made too large, for a high gas velocity must be retained at low speeds. The resistance which the exhaust gases meet when leaving the cylinders is often very high, and considerably reduces the power output. This resistance can be lowered by good valve location, large valve openings, and large and smooth ports and passages. The exhaust valve located in the top of the cylinder head offers much more resistance to the outgoing gases than the L-head location. With the inlet valve the reverse is true. Improvements in the engine of the future cars will be toward an increase in power per cubic inch of displacement, smoother and quiet operation, with freedom from trouble and good economy.

> **THE FUTURE CAR**
>
> **HERBERT C. SNOW**
>
> **All cars will be lighter. The 7-passenger car weight will come below 4000 lb. There will be fewer 8 and 12-cylinder engines. The heavy cars will have 6 cylinders and the lighter cars 4 cylinders. Changes in the engine will be with a view of meeting requirements of low grade fuels.**

"The ignition system is also important to the satisfactory operation of the engine. The single ignition will be more common. While the battery has been adopted as the only source of ignition on a majority of cars, still the magneto will continue to be used, especially on the higher priced cars.

"The location of the transmission as a unit with the engine will, I believe, be the most popular. The majority of the transmissions will have three speeds, but I believe that the four-speed transmission will be developed."

Mr. Crane Sees No Chance to Standardize Types

The industry is likely to retain its present multiplicity of car types, according to Mr. Crane's paper.

"The varying tastes and requirements of different people are such," he said, "that with human nature as it is we will see no great change in this direction. On the other hand, the passenger car is being considered more and more from the sole point of view of a means of transportation, and with less regard as to what might be called its sporting characteristics. We are, therefore, seeing the so-called open car, which in the early days was the backbone of production, being replaced more and more by cars with various types of closed bodies. It is easy to remember when the completely inclosed car, such as the sedan, was extremely rare. To-day it is a standard body type in quantity production on cars of practically every grade of price.

Trend Toward Lighter Weight

"While there has been a continuous effort toward obtaining lighter weight, it has barely been possible in any given car to make up by superior chassis design for a constantly increasing weight of body and equipment. Electric starting and lighting and power tire pumps have had to be provided for, while the use of closed bodies has made absolutely necessary a very considerable increase in the weight of chassis frames. Furthermore, the demand for quietness combined with durability has made it difficult to lighten any of the principal parts of the power plant and driving gear materially, some parts, such as crankshafts, being heavier than ever before. The call for easier riding has made necessary a continuous increase in the weight of springs.

Improvement in Quality Expected

"I hope to see in the near future a very considerable improvement in the quality of our production, both as to

THE FUTURE CAR

HENRY M. CRANE

The trend is toward lighter cars. The closed bodies will be made in increased proportion. There will be a greater mileage per gallon of fuel. Maintenance must be made less of a problem for the car owner.

design and workmanship, in all grades of cars, due to much greater attention being given to ease of maintenance and economy of operation than has ever been given in the past. Many of our lower priced cars are far more expensive to operate than they should be, in view of their light weight. It seems to me that a car in ordinary service which will not give from 25 to 35 ton-miles per gallon is open to serious criticism, in view of our failing supply of gasoline. In the future, cars requiring more than 1 gal. of engine oil for each 100 gal. of gasoline are not operating with an economy that should be readily obtainable.

"I think that we will see an increased use of oil for lubricating other chassis parts outside of the engine, and that this use will be simplified, as it has been in many other commercial lines, by a design allowing for carrying a supply of oil at the various points required, which will need only occasional replenishment."

Torque Recoil and Car Weight

In a paper on "Torque Recoil and Car Weight," L. H. Pomeroy, vice-president of the Institution of Automobile Engineers, London, said:

"In the evolution of the automobile few factors have aroused such discussion among users and engineers as that of the desirable number of cylinders that an automobile engine should possess. Certain American makers have pursued the policy of crowding as many cylinders as possible under the bonnet, with a commercial success that has justified this somewhat peculiar method of meeting the conditions with which they were confronted. The buying public were readily persuaded to accept the multi-cylinder engine, for two reasons: First, the plausibility of the argument that high-gear performance depended upon the number of cylinders per se, and, second, the fact that the said high-gear performance with these engines was beyond all question of a very commanding nature.

"For slow-speed running either throttled down on the level or with open throttle on hills the high-gear performance depends upon the ability of the engine to run slowly and upon the gear ratio. The slow running ability of a four-cylinder engine is practically limited only by its flywheel weight taken as an engine, but when mounted in a car the whole mass of the car may be considered as flywheel mass, provided no definite reversal of torque takes place, such as may be due to misfiring.

"On the other hand, the slow running ability of either a six, eight or twelve-cylinder engine involves a much greater accuracy of valve timing, carburetion and ignition. In my experience I have been able to obtain much better slow-speed running with four-cylinder engines than with six or twelve-cylinder units. It is quite easily possible to throttle a high efficiency engine of the four-cylinder type down to 160 r.p.m., giving a speed of about 4 m.p.h. with a gear ratio of 4 to 1. The impressive slow running performance of the multi-cylinder cars is, in my opinion, much more a function of the gear ratio than of the number of cylinders.

"Without going to extremes, flywheels can be made heavy enough on four-cylinder engines so that when running slowly there is no noticeable variation of angular velocity and hence a jerky motion of the car as a whole. In other words, to judge the uniformity of torque given by a four-cylinder engine as compared with a twelve-cylinder one by superposing the torque diagrams is a gross misrepresentation of the facts.

"It is when the subject of torque recoil is discussed that the advantages of the multi-cylinder engine become manifest. The torque produced by the explosion spends itself in part by accelerating the flywheel, thus producing an equal and opposite recoil which is transmitted to the engine supports. At high speeds this recoil vibration is so rapid as to be practically continuous. The speed at which, other things being equal, this continuity is produced depends upon the number of cylinders and the magnitude of each individual recoil, i. e., at part throttle the effective continuity will occur at a slower speed than at full throttle and will also occur at a slower engine speed, for say an eight-cylinder engine than for a four cylinder. It is clear, however, that with any number of cylinders there is a point at which the torque recoil ceases to be noticed. The point at issue is as to how far it is really necessary to increase the number of cylinders to avoid the manifestations of torque recoil to such a degree as to excite the sensitiveness of the expert driver. Upon this subject the following observations may be made:

"(1) There is in fact what may be called a recoil flywheel effect due to the mass of the cylinders and crankcase. If these were of great weight the torque recoil would be absorbed by these to a large extent instead of being transmitted to the engine support almost in full as is the case with engines of normal weight, particularly at low speeds.

"(2) The mounting of the engine itself plays an important part in the impression of torque recoil continuity. By suitable means the effect of torque recoil in a four-cylinder engine can be damped out, so that even at low speeds it is almost imperceptible. I refer particularly to the method of mounting the engine upon a subframe, thus avoiding the direct recoil which occurs when the engine is mounted directly upon the main frame. It is not possible to reduce this effect to figures easily, but a little consideration will show that even at comparatively low engine speeds the periodicity of the torque recoil is sufficiently rapid that during the time the recoil from one cylinder is being absorbed and delivered to the main frame, another is being imparted, and so on.

"For a given engine speed and gear ratio the torque recoil as has been stated is proportional to the mean effective pressure and the number of explosions per unit time. Increasing the size of cylinder, but keeping the torque the same, will, therefore, not affect the torque recoil, owing to the consequent reduction in brake mean pressure for a given torque. Torque recoil then is independent of the cylinder size for any given torque. Increasing the number of cylinders, keeping the torque the same, will reduce the torque recoil effect in proportion to the increase in the number of explosions per minute.

"From the point of view of power and acceleration cars may be classified in terms of the power exerted by the engine, the road speed at which this power is exerted and by the total weight. These factors determine the acceleration or liveliness of the car, its capacity to climb hills and to accelerate. For any given gear ratio, then, the horsepower of the engine should be in proportion to

the total weight. The low limit of the high-gear ratio is determined by the maximum speed at which the engine will run and give a satisfactory road speed.

"For automobile engines of moderate size, say not exceeding 4-in. bore and 6-in. stroke, the limiting speed, or that at which the maximum power is attained, does not vary greatly, being somewhere between 2500 and 3000 r.p.m. For the purpose of discussion, there is no reason why the same gear ratio should not be used with an engine of say 4-in. bore and 6-in. stroke, as with an engine of 3½-in. bore and 5-in. stroke. It is clear, then, that for the same high-gear ratio power in proportion to the total weight may be read as torque in proportion to the total weight.

"From the user's standpoint the multi-cylinder engine is regarded as advantageous in respect to high-gear work on the hills and on the level, characteristics in which such engines have certainly no advantage in respect of the number of cylinders per se. The prevalence of this opinion is a costly one for both the industry and the owners, however useful it may have been as a sales policy to save a situation endangered from other causes. It will be interesting to see how far the economic considerations which are the basis of all sound engineering will ultimately affect design in the respects discussed.

"I am strongly of the opinion that in the near future the chassis will be designed to suit the body work and that there will be broadly two types of chassis, the one suitable for heavy closed and open bodies and the other suitable for bodies of the roadster type. Such a development would lead probably to the conclusion that the light chassis would be capable of dealing with considerably heavier bodies than those for which it was originally designed. This would allow the lightening process to be repeated without involving the commercial danger of marketing a light chassis for all purposes. As has been shown, a reduction in car weight would enable the existing standards of performance to be maintained and even improved with the use of four-cylinder engines for the lighter chassis and a maximum of six cylinders for the heavier type and all that this means in its tremendous advantages to the automotive industry and to the user."

THE FUTURE CAR

L. H. POMEROY

The 4, or at most, the 6-cylinder engine will meet all demands. This change will be of an economic value. The future chassis will be made in 2 types, one for heavy bodies, the other for roadster type. I look for the lighter chassis to be used with the 4-cylinder engine and the heavier body with the 6-cylinder as a maximum.

New British Low-Priced Car

A LIGHT car, assumedly built to compete with American productions both as regards price and scale of manufacture, has just made its appearance in England. It is the product of Wm. Cubbitts & Sons of London.

The engine is a four-cylinder monobloc, with the head separate and integral with the water outlet pipe. The bore and stroke are 80 x 140 mm. (3.15 x 5.5 in.), giving a capacity of 2185 cc. (133 cu. in.). The crankshaft is a forging ground on the journals only, and there are three main crankshaft bearings of great length. At the end of the crankshaft itself is a helical gear operating the camshaft. Connecting rods of H section are used, with bronze bushings for the piston pins. Special bronze buffer pieces are fitted at the ends of each piston pin, to prevent it scoring the cylinder walls. The cams and shaft are in one piece, which runs in three bearings, the camshaft being increased in diameter at these three points.

The valves are of nickel steel, and are operated by discended tappets having adjustable heads, the cams striking these tappets in such a manner as to cause them to rotate.

The ignition, lighting and starting sets are on orthodox American lines. No magneto is fitted, the current being taken through a battery and coil from the lighting dynamo. The starter is of the usual Bendix drive type.

Crank bearings are lubricated by an automatic pump run off the camshaft. Enough oil escapes from the big-end bearings to lubricate the cylinder walls and piston-pin bushings, and the lowest of the three piston rings is fitted with a skirt to prevent too much oil reaching the combustion chamber.

The oil pressure gage is of novel character, and most ingenious. Oil is led from the engine to one side of a thin steel diaphragm. Any oil pressure must therefore bend the diaphragm. On the other side of this diaphragm is a chamber filled with red liquid, and leading out of this chamber is a single glass tube. As the oil pressure rises, it forces the red liquid up the tube in sight of the driver, the tube being placed in a special socket on the dashboard. As this would be difficult to see at night, the back of the tube is coated with a luminous preparation, which makes it clearly visible even on the darkest night.

The cooling is by gear pump through a very high radiator placed in front of the car. The carbureter intake manifold is waterjacketed.

Housed in a special coned ring bolted to the cast-iron flywheel is an inverted, fabric-lined cone clutch. The cone itself is an aluminum casting, and the pilot bearing consists of two ball races. The universal joints are of the fiber, or fabric, type, one in front of and one behind the gearbox. The latter is of cast iron and carries four speeds forward and one reverse. There is an exceptionally large cast-iron lid for the gearbox, which makes the whole mechanism readily accessible. At the rear end of the gearbox is a contracting fabric-lined brake, operated by a cam mechanism connected with a pedal. The arms for the forward fabric disc joint of the propeller shaft form part of this brake drum, and the propeller shaft itself is taken direct from this joint to another, similar in every way, bolted to the pinion shaft of the back axle. The back axle is of the helical-gear type.

The wheels are of the pressed-steel disc type and are easily detachable by unscrewing five nuts on the hub. From the owner's point of view the chassis lubrication of the car is exceptionally good, there being not a single grease cup on any part of the mechanism.

The standard body is a five-passenger touring, built entirely of steel by the Messrs. Cubbitts. An idea of the size of the machine may be gained from the fact that it has a 126-in. wheelbase.

The car will be completely equipped with a self-starting and lighting set, five lamps, top, adjustable windshield, and spare wheel with tire and tube. The price is $1,100 and it is hoped to produce more than 20,000 cars next year.

THE manufacture of parts to gages, so as to make them interchangeable, is believed to have been introduced by Colonel Colt in the manufacture of rifles at the time of the Civil War.

S. A. E. SUMMER MEETING

How the Automotive Industry Can Help Avert a Fuel Crisis

Do Not Attempt to Solve This Problem by Trial and Error, but Organize, Study and Build Co-ordinately for Industrial and Scientific Achievement, Advises Authority

OTTAWA BEACH, Mich., June 24.—Prof. Joseph E. Pogue made an earnest appeal at the S. A. E. Summer Meeting today for prompt and concerted action by the automotive industry toward solving the fuel problem. He said that the industry should assume its share of the responsibility for meeting the coming shortage of motor fuel, which he regarded as increasingly serious.

Prof. Pogue's paper was supplemental to his article published in AUTOMOTIVE INDUSTRIES on June 12 (Engineering Issue). In that paper he presented his reasons for believing that the shortage was inevitable, due to the shortage in the basic supply of petroleum and that this shortage, unless overcome, would develop into a serious handicap on the industry. The speaker represented the Division of Mineral Technology, U. S. National Museum.

In his paper read today Prof. Pogue outlines what he believes should be undertaken. He said in part:

"The automotive industry has an unescapable concern in the problem because the highly specialized fuel requirements of the prevailing type of automotive apparatus limits the quantity of engine fuel that may be commercially produced from the output of crude petroleum. * * *

"The low thermal efficiency or high fuel consumption of the prevailing type of automotive apparatus contributes strongly to the demand for engine fuel, requiring gasoline to be produced in far greater quantities than would be necessary if the fuel were more efficiently utilized. Every gain in thermal efficiency, therefore, means a corresponding increment to the fuel supply. Increased thermal efficiency may also be made to compensate the consumer for such advances in fuel prices as may develop. Thermal efficiency, therefore, has a pivotal bearing upon the quantity and price of engine fuel and though now tending to work to the disadvantage of the automotive industry may be turned to its advantage.

"On four counts, the automotive industry finds itself responsible in respect to fuel where it had no concern in the past. If the conclusion is correct that fuel is now to dictate to the engine, the engine should listen well to all that fuel has to say.

What Has Been Done

"In the past few years there has been a growing recognition that the rapid advance in automotive construction was creating a fuel problem which the automotive interests themselves would have to share in solving. This feeling, however, was scattered and ill-defined and did not find official recognition until the 1919 Annual Meeting of the Society of Automotive Engineers, when a session was devoted to a consideration and discussion of the engine-fuel situation.

"In the spring of 1919 the second stage in the solution of the problem was entered upon with the establishment of a committee of the Society of Automotive Engineers charged with considering ways and means for active work on the fuel problem. A fuel research organization was projected by this committee and the organization, scope and program of the new agency are now (June) under formulation. At the same time the newly formed American Petroleum Institute, representative of the oil industry, has under advisement the establishment of an agency of contact and co-operation with the automotive activity. Thus the initial machinery has been established." * * *

Functions of a Research Organization

According to the speaker the action necessary to secure a solution of the problem involves three stages:

1—Economic analysis to determine what is needed to be done.
2—Material research to build up new technology.
3—Co-ordination between the industrial activities concerned to facilitate the adoption of a new technology and to remove cross-purpose development.

"It cannot be emphasized too strongly that the problem is not one that will yield to dissociated research alone. The activity connoted by the term 'research' has unfortunately taken on a very narrow meaning in the popular mind, at the same time that it has assumed a sort of magic quality as being a panacea if only applied intensively enough. The gravest danger at the present stage in the development of a fuel research organization is that it will be projected along conventional lines too narrow to admit the full range of technique—analysis, material research, co-ordination—essential to adequate progress.

The Role of Economic Analysis

"The part that economic analysis should play in connection with material research has not been absolutely ignored in the past, but it has not been accorded its due rank as a matter open to rigorous scientific cultivation.

"It should be clearly appreciated that the factors in

the engine-fuel situation are in course of constant change, and no program of work can be effective which is not based upon careful, scientific evaluation of these variables. The problem, being composed of variables, then, is distinctly not a static matter, and accordingly it cannot be treated as if it were a fixed specific issue.

"More specifically still, it is conceived to be the function of economic analysis to study and interpret the various engine fuels, such as gasoline, kerosene, fuel oil, benzol,, alcohol, shale-oil distillate, etc., in respect to resources, production, trend of prices, economic status, interrelationships, technical development and so on. At the same time, in the light of their bearing upon fuel, the various automotive developments should be appraised, in respect to output, efficiency, trend of changes, price relationships, etc.

The Role of Research

"Research is a tool for building up technology in any direction desired. To be effective, it should be applied to critical and pivotal points. Results are too laggard and costly, if research is not directed by economic need, although the term should be given a broad interpretation in this respect.

"Enough is already known of the economics of the engine-fuel situation to feel that among the matters calling most insistently for research are carburetion to permit the use of difficulty vaporizable fuels and combustion to increase thermal efficiency.

"To secure proper research attention to these and related matters will require the co-ordination of the many individual research activities—industrial, governmental and university laboratories, etc., which now have facilities for conducting research; and a central laboratory to devote adequate attention to the more basic and elaborate lines of work not adequately being handled by the individual agencies.

The Role of Co-ordination

"There must in addition be a bringing together, a co-ordination, of the various industrial activities concerned under a consistent and harmonious policy, which will insure an appropriate adoption of technologic advances and especially smooth out such competitive cross-currents as may be blocking a favorable development of the matter. The utmost in investigation and research will avail nothing, if the aggregate of policy is not brought under a measure of scientific control sufficient to insure a harmonious development in respect to fuel.

"Since both fuels and engines are in course of change, though periodically standardized, it is obvious that a paramount problem is to insure, so far as possible, a parallel and complementary development of the two.

"If it should turn out that trucks and tractors adopt the heavy-oil engine as an outcome of experience, a remedial loss will have been sustained if this is allowed to come about by a process of trial and error.

"On the basic issue of fuel policy, competitive effort may advantageously give way to co-operation. As an illustration, the fuel policy most advantageous for the tractor industry is contingent upon the fuel policy adopted by the truck industry, and in turn is not unaffected by what is developing in respect to passenger cars. Without the closest understanding between the three, the tractor policy would stand only the vaguest chance of being correct.

The Type of Organization Requested

"It is probable that many who have given attention already to the engine-fuel problem have felt disappointed that a more definite and specific program for attack has not been offered. The present undeniable state of perplexity as to exactly what should be done is due to the fact that no one knows, nor can know, in advance, exactly what should be done. I think that the practical step now is to establish an organization broad enough to attack the problem at all its vulnerable points. If this is done on a scale commensurate with the magnitude of the issue and with a personnel equal to the responsibility, the industry may feel assured that it has taken the only practical step toward bringing the full quota of modern scientific methods to bear on the matter."

Lively Discussion of Dr. Pogue's Paper

In opening the discussion of Dr. Pogue's paper, Chairman Bachman outlined the activities of the S. A. E. in connection with the fuel problem since last February. Two meetings, he said, had been held, one at Washington and one at New York, at which the outlook had been discussed jointly by representatives of the automotive and of the oil industry. A joint committee was established, Mr. Bachman said, which would lay out a program of work somewhat as outlined in Dr. Pogue's paper.

Mr. Hinkley complained that engine builders were asked to design their engines to use very divergent fuels. The city of Detroit had approached the fuel problem and drafted comparatively simple specifications based on the distillation characteristics which the fuel sold in the city must meet. This had solved the problem there for the time being. The engine builders wanted "a mark to shoot at," he said, and would like to have the subject of fuel characteristics settled for five years at least. If a man bought a first-class car, he sometimes deluded himself that it would last him a lifetime, but in a few years it would not burn the fuel then available.

Mr. Cardulls said there were five lines of attack on the fuel problem that had occurred to him:

1—To forbid the use of the lighter petroleum fractions in fuel oil.
2—To encourage the development of an automatic gas generator for producing a fixed gas from the heavier hydrocarbons for use on trucks and tractors.
3—The development of engines and carbureters for heavy oil.
4—The induction of more economical vehicles, possibly of reduced high gear ability, and having a greater number of gears.
5—The production of a sympathetic fuel, drawing upon all the various fuel sources available.

Mr. Smith said that it was up to engine designers to meet the problem. Local restrictions would not solve it. It was also pointed out in the discussion that the public should be exhorted to economize.

As an instance as to what expenses we have gone in powering passenger vehicles, it was stated that on a certain high-grade car the throttle was opened 12 degrees 50 minutes when running at 50 m.p.h., over a smooth level highway. Another fact that tends to enhance the scarcity of motor fuel is that gas companies are using fuel oil to enrich their gas, as the practice

S. A. E. SUMMER MEETING

Visualizing the Future Truck

Why It Will Have 4-Speed Transmission
Changes for the Pneumatic Tires
Developing an Ability Formula

OTTAWA BEACH, MICH, June 24—The future of the truck was the chief topic at the morning session. Louis P. Kalb discussed the relative high and low gear ability of the truck of the future and the changes that must be made in the design of the truck to make pneumatic tires an economical part of the equipment.

Mr. Kalb, who was assistant supervisor of engineering of the Standard Parts Co., Cleveland, Ohio, presented his paper under the title, "The Relation of Motor Truck Ability to the Trend of Design," as follows:

This article is intended, however, to treat the subject of motor truck ability from the standpoint of its relation to present trend of motor truck design, attempting to set forth some of the fundamental considerations involved therein.

All engineering calculations are based upon what may be termed "factors of experience." For example, in calculating the section of a front-axle I-beam, a formula is used containing that stress which experience has shown to be safe for this particular duty. The purpose, then, of an ability formula when applied to automotive vehicles is to determine a "factor of experience" from which the proper engine size and gear ratios can be calculated.

Measurement of Performance

The performance of automotive vehicles is properly measured by their comparative ability to perform the function for which they are intended. It is logical then that passenger car performance be measured in terms of speed and acceleration. In the case of motor trucks, however, these are not the most important considerations, it being almost universal practice to limit the speed by a governor, which in itself minimizes the importance of acceleration. Furthermore, wind resistance is negligible, so that practically the only resistances to be overcome by a motor truck are road friction and the force of gravity. The performance of motor trucks can therefore be measured simply by their ability to overcome these two forms of resistance.

Now both road and grade resistance are in direct proportion to the weight carried and can be expressed in unit terms such as pounds per pound and pounds per ton of total load.

If the tractive force which the driving wheels of a truck are capable of exerting be expressed in the same terms, it then becomes a simple matter to compare the resistance to be overcome with the force available for doing it. This unit tractive force is therefore the best index of the ability of a motor truck.

It might be well to call attention to the incorrectness of the idea held by some that a truck's ability is affected by the location of the driving wheels and the distribution of the load. The fact is that it makes no difference whether the drive be through the front, the rear, or all four wheels, or whether the load be carried on the truck or on a trailer; the total resistance and consequently the force required to overcome it will be the same. There are in more or less general use a number of ability formulas of indisputable merit, and, in addition to these, many engineers have their own pet ways of expressing ability which best serve their own purposes. All of these formulas are based upon the same fundamentals and to consider the subject in an intelligent manner, let us get a correct understanding of these fundamentals by building up from first principles.

Ability Formula

The maximum tractive force available at the tires of the driving wheels is expressed by the following formula:

$$F = \frac{2\,GA\,R\,E}{D} \text{ where} \qquad (1)$$

F = Tractive force in lb.
GA = Maximum brake torque of engine in in.-lb.
R = Total reduction of ratio of engine to wheel speed
E = Efficiency between engine and wheels
D = Diameter of driving wheels in in.

Now the engine torque may be expressed in terms of piston displacement as follows:

$$GA = \frac{Pb\,V}{12.56} \text{ where} \qquad (2)$$

GA = Engine torque in in.-lb.
Pb = Brake mean effective pressure in lb. per sq. in.
V = Total piston displacement in cu. in.

Substituting this value for GA in equation (1), we have the tractive force expressed in terms of piston displacement.

$$F = \frac{V\,R\,Pb\,E}{6.28\,D} \qquad (3)$$

The tractive force per unit of weight may be expressed

$$T = \frac{F}{W} = \frac{V\,R\,Pb\,E}{6.28\,D\,W} \text{ where} \qquad (4)$$

W is the total weight of the vehicle, body and load. Now if W is expressed in tons, T will be the tractive force in pounds per ton, and if in pounds T will be expressed in pounds per pound. Both methods of expression have their advantages. Road resistance being commonly expressed in pounds per ton, it is, of course, convenient to express ability in the same terms. However, as will be

shown later, grade resistance is more conveniently expressed in pounds per pound. It also seems that the formula should contain only one unit of weight. In my estimation, therefore, the best measure of truck ability is the tractive effort in pounds per pound.

All of the factors involved in equation (4) can be readily determined with the exception of mean effective pressure and efficiency. Both of these quantities are rather indeterminate. Not only do different designs of trucks vary considerably in respect to these features, but even trucks of the same make and type are quite likely to show an appreciable difference.

Pb being the index of engine output per unit of piston displacement, is, of course, affected by all the factors by which engine output is controlled, such as carbureter setting, ignition and valve timing, condition of valves, pistons, etc. Efficiency is also affected by many factors, such as design of transmission and axle, type of drive, effectiveness of lubrication, etc.

When possible it is, of course, desirable to use values determined by actual tests made on the truck under consideration. This generally involves much time and effort, which makes this information rather difficult to obtain. To make this formula general in its application and easy to apply, we will assume certain values of *Pb* and *E* which approximate as closely as possible the average values for various designs of engine and types of drive. A good average value for *Pb* is 85 lb. per sq. in. A number of truck engines develop more than this on the block, some giving as high as 93 lb. per sq. in. However, very few engines give this later output on the road, and the lower figure approximates very closely what can be expected from most truck engines in service.

It has been quite common to assume *E* to be 85 per cent on direct drive and 70 per cent in gear. Recent tests show that a more correct assumption would be 90 per cent on direct drive and 85 per cent in gear. Substituting these values in equation (4) we have

$$T = \frac{12.15\, V R}{D W} \text{ in direct drive} \qquad (5)$$

$$T = \frac{11.5\, V R}{D W} \text{ in gear.} \qquad (6)$$

to distinguish *T* from other factors for expressing ability, I shall hereafter refer to it as the "ability coefficient."

The hill-climbing ability of a truck may be expressed in terms of ability and road resistance by the following formula:

$$G = T\left(\frac{1 + R^2}{\sqrt{T^2 - R^2 + 1} - T R}\right) - R \text{ where} \qquad (7)$$

G = Per cent grade truck can just climb with road resistance R
T = Ability coefficient in lb. per lb.
R = Road resistance in lb. per lb.

For the average values of *T* and *R*, the quantity in the parenthesis is so close to unity that for all practical purposes, the formula can be expressed

$$G = T - R \qquad (8)$$

In other words, the grade that a truck will climb is equal to the net drawbar pull expressed in pounds per pound.

Let us compare equations (4), (5) and (6) with some of the other ability formulas now in use. H. K. Thomas's ability formula is expressed as follows:

$$Q = \frac{3000\, d^2 s n r}{D W}$$

C. T. Myers's vehicle coefficient is expressed

$$V C = \frac{8 n d^2 s r}{D W}$$

while the formula suggested by Mr. Roebuck is

$$K = \frac{14{,}550\, d^2 s n r}{D W}$$

The similarity of all these formulas is apparent. Each one involves piston displacement per unit of weight moved a unit distance and differs only in the constants and assumed values for engine output and efficiency.

The vehicle coefficient of Mr. Myers and the ability coefficient expressed in equations (4), (5) and (6) possess the advantage that they represent a concrete quantity and can be used to determine drawbar pull and hill-climbing ability. If it were desired to make the expression for ability an abstract quantity which could be used for comparative purposes only, the formula

$$K = \frac{V R}{D W}$$

would answer all requirements. This formula involves only known variables and is reduced to the simplest terms.

As stated previously, any expression of ability involves piston displacement per unit of weight moved a unit of distance. A rearrangement of equation (4) will illustrate this point.

$$T = \frac{Pb\, E}{2} \times \frac{V R}{\pi D W}$$

and the second factor equals cubic inches of piston displacement per pound moved 1 in. Motor truck fuel consumption is generally expressed in pints per ton-mile. On account of the varying throttle openings, it cannot be said that fuel consumption will vary directly as the piston displacement; nevertheless, other things being equal, the greater the piston displacement, the greater the amount of fuel drawn into the engine during a given number of revolutions, and consequently, the greater the ability, the greater will be the fuel consumption per ton-mile. Therefore the penalty that must be paid for ability is reduced fuel economy.

If road and grade resistance were constant it would be quite a simple matter to design for an ability just sufficient to overcome this resistance and we would thus have a maximum economy at all times. However, hills do exist and road resistance varies widely. In some localities the grades never exceed 6 per cent, while in others they run as high as 30 per cent. Road resistance varies from 0.0075 lb. per lb. for good asphalt, to 0.1800 lb. per lb. for a sand road, loose sand and plowed ground going even higher than this.

High-Gear Ability

To determine in advance just what the ability of a truck should be would appear a rather difficult task. In general, it can be said that high-gear ability should be sufficient to overcome average road resistance with a sufficient surplus to climb the grades that are encountered with such frequency that gear shifting would be objectionable. The low-gear ability should be sufficient to overcome practically the worst conditions of grade and road.

A study of the abilities of existing trucks shows that practice varies widely upon this point. In the smaller sizes, ranging from 1000 to 2000 lb. capacity, there seems to be a tendency toward passenger car ability. This seems quite logical, for most of these trucks run on pneumatic tires and at speeds which call for that ability necessary for acceleration and overcoming wind resistance.

Some of the most successful vehicles in this class have a high-gear ability coefficient of from 0.085 to 0.090. It might be noted that this is greater than foreign practice for passenger cars, but somewhat lower than American passenger car practice, which varies from 0.085 to 0.105.

In the larger sizes of truck, that is, from 1½ to 6 tons capacity, operating at moderate speeds and on solid tires, abilities vary from about 0.06 to 0.08 lb. per lb. A good average of present successful practice would be around 0.0675 to 0.074.

In determining the proper ability coefficient to use in new designs, it would be unwise to follow present practice blindly. In fact, it is my opinion that the proper high-gear ability for a truck is much lower than the average figure given above. There are a number of causes which tend to make the average engineer lean toward excessive ability. The fact that it is so difficult to determine just what proper ability is, leads the engineer toward unnecessarily high ability just for the sake of being on the safe side.

Until recently, the great majority of trucks on the market had three-speed transmissions with rather limited low-gear reductions. Undoubtedly excessive high-gear abilities were necessary in many cases to have anything like adequate ability on low gear. Furthermore, the great majority of truck buyers judge a truck merely by its power, forgetting entirely the effect that excessive ability has upon economy.

Engineers must, of course, design what the public wants or thinks it wants. An effort should be made, however, to educate users on this point and bring them to understand that high ability costs money. Some consistent propaganda along this line would undoubtedly cause truck users to modify their demands appreciably.

The use of trucks in country districts is increasing, but it is hardly right to penalize the great majority of trucks which are operated on improved roads for the sake of the few that operate in rural districts over unimproved roads.

The fuel problem is one which is becoming more serious daily, and the constantly increasing number of trucks in service is certainly not tending to alleviate the situation. If this growth is to continue unhampered, something must be done both to improve truck economy as well as to enable trucks to operate upon the poorer grades of fuel which are now available.

The truth of this statement is shown by the fact that marine engines, whose power factors are much lower than those of passenger cars or trucks, operate satisfactorily on kerosene. This has never been successfully done with either trucks or passenger cars.

Ideal Design of Truck

The ideal design of a truck is one which combines maximum economy with adequate ability. Now, since trucks operate at least 90 per cent of the time on high gear, the interests of economy will be served if we keep high-gear ability down to the minimum. In my opinion, the ability coefficient in high gear should be about 0.063 to 0.066 lb. per ton. As stated previously, the low-gear ability of a truck should be sufficient to overcome the worst conditions of road and grade. This is a requirement which it is impossible to fulfill entirely. The best that can be done is to utilize all of the ability that the adhesion of the driving tires will permit. This can be done by making the low-gear ratio sufficient to almost slip the wheels under full engine torque.

The coefficient of adhesion of solid tires to dry macadam is about 0.60, while on a sand or mud road it would not exceed 0.45. It is on the latter type that the greatest ability is required. Therefore, if the tractive force be made about 45 per cent of the load on the rear wheel, we will have the maximum ability that the traction of the driving tires will permit.

The proportion of total weight on the rear tires is about 77 per cent. The low-gear ability coefficient should therefore be

$$T\,L = 0.770 \times 0.450 = 0.346 \text{ lb. per lb.}$$

The low-gear ratio of the transmission should then be

$$r = \frac{0.346 \times 0.900}{0.063 \times 0.850} = 5.8 \text{ to } 1$$

Such a low-gear reduction as this would, of course, require a four-speed transmission. About the maximum ratio obtainable with a three-speed transmission is 4 to 1, and anything greater than this would cause very unsatisfactory gear changing. Four-speed transmissions have in the past been the exception, and even those which did exist did not have anything approaching the proper low-gear ratio. In fact, the idea of utilizing all of the available traction on low gear seems to have become popular in the last few years.

The Class B truck is, in a way, responsible for the rapid growth of the idea, although not for its inception, as it afforded engineers a large scale demonstration of the principle. Anyone who has seen the B truck negotiating roads and grades over which other very good trucks were unable even to move could not but be impressed.

Increasing Low-Gear Ability

Increasing low-gear ability will, of course, require a proportionate increase in the size of torque-carrying members back to the transmission, such as propeller-shafts and live axles. However, the design of such parts to meet these conditions is a very simple and exact proposition. Since the torque required for slipping the wheels is a definite proportion of the load upon the tires, the torque and load-carrying members of the axle can be proportioned accordingly. Since it is impossible to impress a torque upon the axle greater than the adhesion of the tires will transmit, it will be impossible with an axle so designed to over-stress the torque-carrying members no matter how large an engine or how low a gear ratio is used.

Propeller-shaft brakes also cease to be a bugaboo, for tire adhesion limits braking torque just as much as it does propelling torque. The advantages of this should appeal to axle manufacturers. Even without increasing the strength of the torque-carrying members increased low-gear ability should tend to reduce rather than to increase the strain on these parts. With adequate low-gear ability it is no longer necessary to speed up the engine and drop in the clutch suddenly to get out of bad holes. Instead, an even, steady torque is applied, which does much less harm than the shock of a suddenly applied torque. I know of an instance where the breakage of live axles was actually eliminated in a fleet of trucks operating in a very severe service by increasing the low-gear ability.

The objection raised to reducing high-gear ability is that such a move would not meet with favor in the eyes of truck users. To judge the merits of this objection, let us compare the hill-climbing abilities of two trucks, one with a high-gear ability coefficient of 0.072 and a three-speed transmission with a low-gear reduction of 4 to 1 and the other with a high-gear ability coefficient of 0.063 and with a four-speed transmission having a low-gear reduction of 5.8 to 1. Assuming that the road resistance is 0.03 lb. per lb., the three-speed truck will

be able to climb a grade of 4.2 per cent on high gear. On low gear this truck will have an ability coefficient of 0.272 lb. per lb., and will be able to climb a grade of 24.2 per cent. The truck with the four-speed transmission will be able to climb a grade of 3.3 per cent on high gear. On low gear this truck will have an ability coefficient of 0.345 lb. per lb., and will be able to climb a grade of 31.5 per cent.

Now where is there a driver who can distinguish between a 3 and a 4 per cent grade? The difference between a 24 and a 31 per cent grade, however, is quite appreciable.

The maximum ability of a truck is that on low gear, and consequently the power of a truck will be judged more by its low-gear than by its high-gear ability for the same reason that the speed of a truck is judged from its maximum or high-gear speed.

Any trend of design, to survive, must be fundamentally correct. I have endeavored to set forth some of the principles upon which the present trend toward four-speed transmissions is based and to show why the trend is bound to grow in spite of the inertia which all radical changes in design must overcome.

There is another trend in the motor truck field in connection with which the matter of ability should be given some careful consideration. That is pneumatic tires for large trucks. I will not attempt to discuss all of the problems involved in this subject which are perplexing truck engineers at the present time, such as brakes, turning radii, body height, etc., but will confine myself to the problems in which the question of ability is involved.

The strongest reason for the use of pneumatic tires on heavy trucks is to be able to increase the speed and consequently the ton-miles per day without injury to the vehicle. From a standpoint of dollars and cents, I do not see how pneumatic tires can be sold to replace solid ones unless this is accomplished. Undoubtedly the cost of pneumatic tires is higher than that of the solid type, and unless the owner is able to get an increased return on his total investment, due to an increase in ton-miles, he cannot be induced to invest the extra money in pneumatic tire equipment. Increasing the truck speed means an increase in engine speed or a reduction in gear ratio. It certainly is not desirable to increase engine speed, for, as surely as this is done, an increased amount of trouble will result.

Now any reduction in gear ratio will result in lowered ability. No one knows whether road resistance is more or less with pneumatic than with solid tires. This much we do know, however. When the speed of a truck is appreciably increased, the ability should approach closer to that of passenger cars. Road and grade resistance are no longer the only forms of resistance to be overcome. Not only does wind resistance become a considerable factor at higher speeds, but the car must have an ability reserve to accelerate to this increased speed within a reasonable length of time. Thus, the use of pneumatic tires calls for not only increased speed, but increased ability. Power being the product of force by velocity, it is evident that the engine must develop horsepower. It being inadvisable to increase the engine velocity, it is evident that the engine must develop greater horsepower. It being inadvisable to increase the engine speed, there is only one thing left to do, and that is to increase the size of the engine. This means a corresponding increase in the transmission drive shafts, and, in fact, in all the power-transmitting parts of the chassis. There is no doubt that the use of pneumatic tires will permit an appreciable reduction in the weight of all load-carrying parts of the chassis. I am inclined to believe, however, that this saving will be offset by the increase in the engine and other power-carrying members, so that there will be n ultimate saving in weight or cost.

PNEUMATIC TIRE TRUCK

KALB *says:*

The added cost of tires must be covered by the increased ton-miles per day by speed.

Reduction in gear ratio means less ability, so speed must be gained by larger engines.

Pneumatic tires will permit reduction in weight of carrying parts, but this will be overcome by heavier engines.

To operate successfully on pneumatic tires, the truck chassis should have characteristics of large passenger chassis.

Let us compare a 3½-ton truck, intended to operate on solid tires, with one designed especially for the pneumatic type. The specifications of the solid-tire truck may be assumed somewhat as follows:

Total weight of vehicle, lb.	15,300
Rear tire size, in.	36 x 5 dual
Speed, miles per hr.	14
Engine size, in.	4½ x 5¾
Piston displacement, cu. in.	365.8
Axle ratio	8¾ to 1
Engine speed, r.p.m.	1141
Ability coefficient, lb. per lb.	0.07

For the pneumatic-tire truck, let us assume a speed of 20 miles per hr. At this speed we should have an ability of about 0.08 lb. per lb. in order not to exceed 1200 r.p.m. engine speed. With 44 x 10-in. rear tires the axle ratio should be approximately:

$$\frac{1200}{152.6} = 7.87 \quad \text{say } 7\tfrac{3}{4} \text{ to } 1$$

The piston displacement would then be

$$V = \frac{D\,W\,T}{12.15\,R} = \frac{44 \times 15{,}300 \times 0.08}{12.15 \times 7.75} = 578 \text{ cu. in.}$$

This is approximately the displacement of a 5½ x 6 or a 5¼ x 6½-in. engine, and is even larger than is used for a 5-ton truck on solid tires.

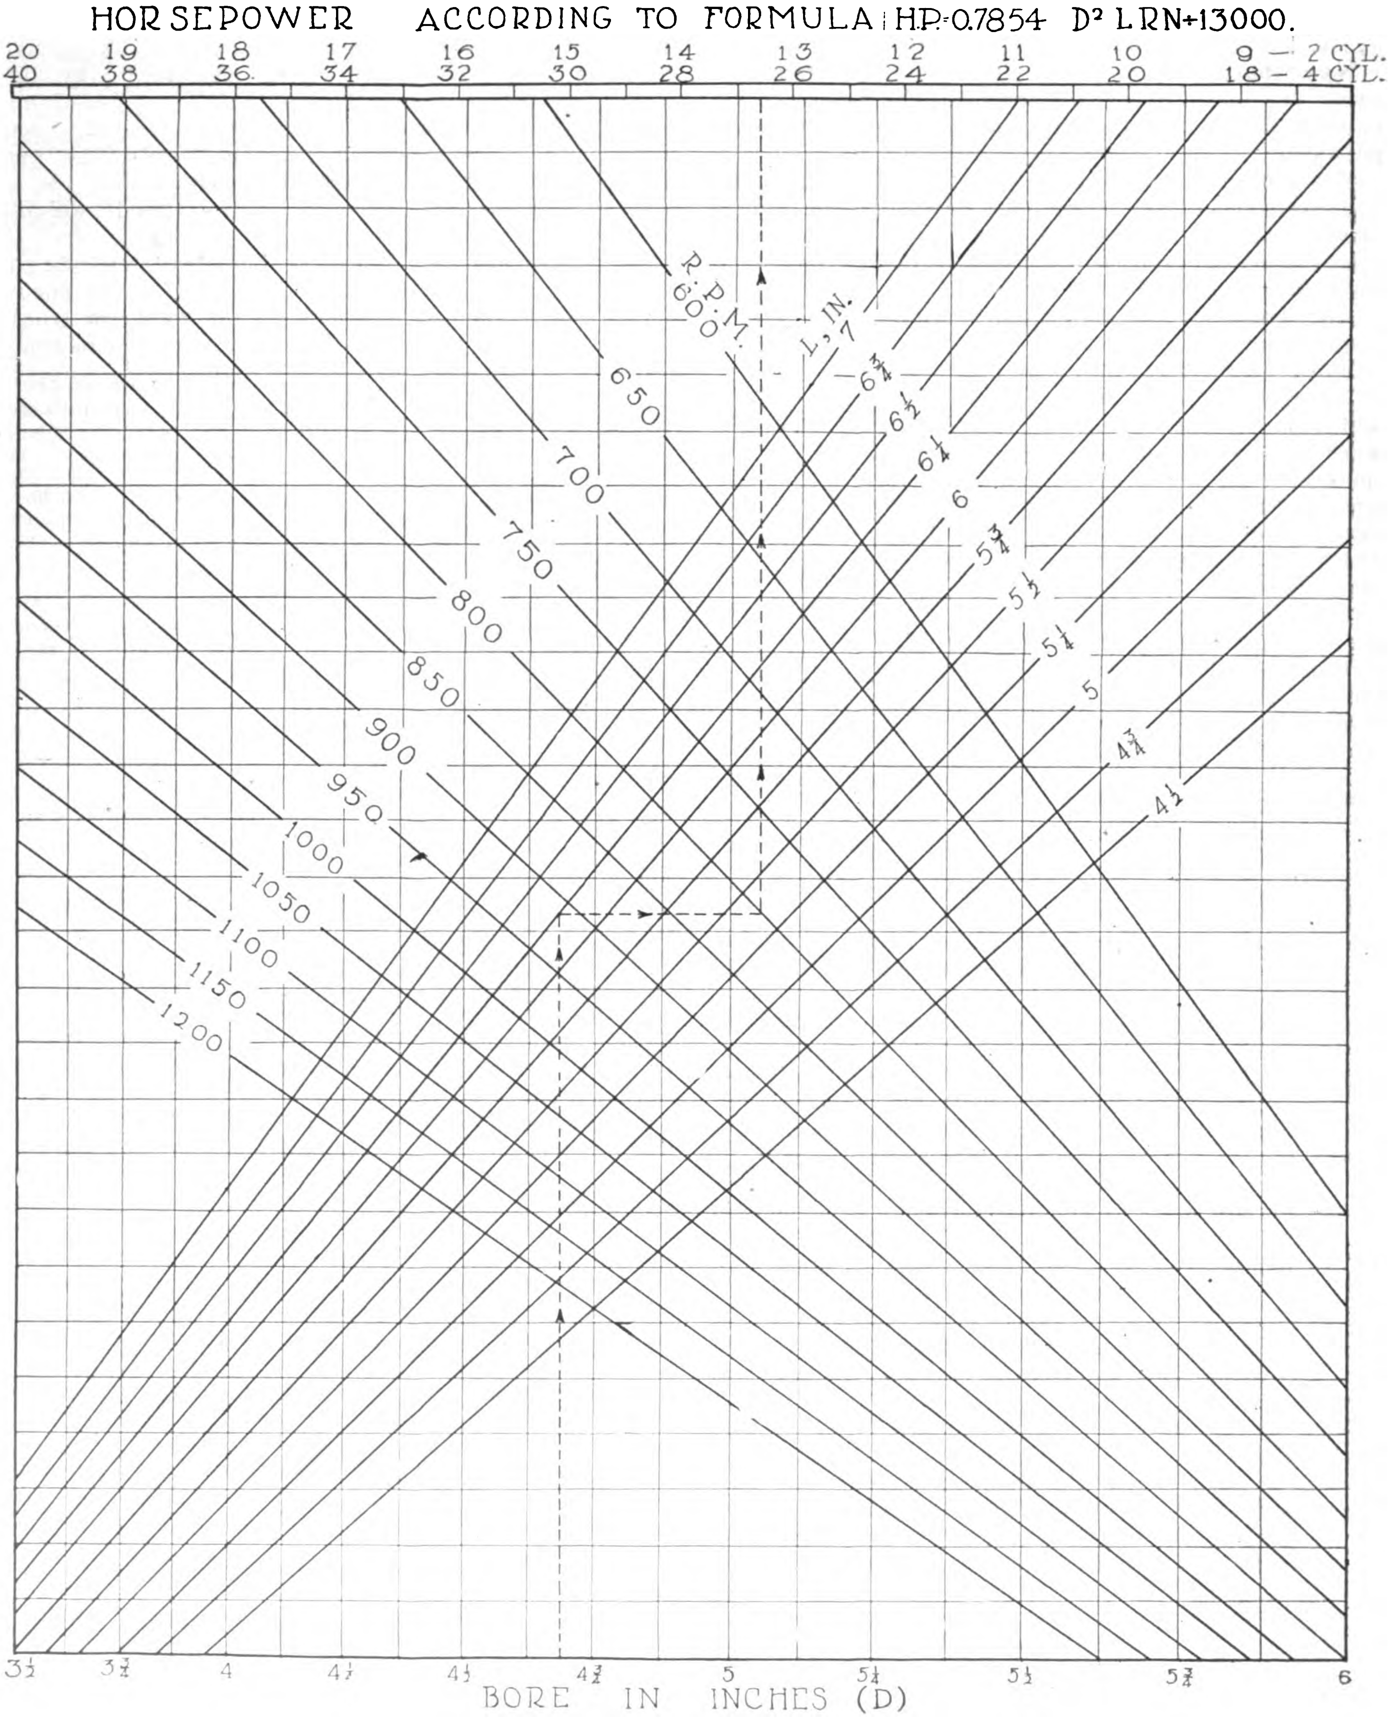
I do not wish to be understood as opposing pneumatic tires for trucks. In fact, I believe that the increased use of pneumatic tires will greatly widen the field of usefulness of motor trucks, and should be encouraged by all truck builders. **The point that I wish to bring out, however, is that high-speed pneumatic-tire trucks and slow-speed solid-tire trucks are fundamentally two very different propositions and should be treated as such. To operate successfully on pneumatic tires a truck should be especially designed for this service and should partake more of the characteristics of a large passenger chassis than do the trucks now operating on solid tires.**

In conclusion, I want to impress upon you the fact that ability is not an abstract quantity of purely academic interest, but is a factor having a direct bearing upon the most important problems of motor-truck engineering.

The Discussion

President Moseley asked A. B. Bachman, chairman of the Standards Committee to take the chair for the discussion, because of his practical knowledge of the truck situation. The rooms were filled to capacity for this session, as it was understood that there were to be interesting developments. (*Continued on page* 1451)

Tractor Rating Chart Prepared by the S. A. E.



S. A. E. SUMMER MEETING

Standards Committee Rejects Only One Proposal of Divisions

Tank and Radiator Cap Recommendation Fails—Lively Discussion Over Adoption of Formula Engine Rating as Suggested by Tractor Division

OTTAWA BEACH, MICH., June 23.

THE sharpest discussion in the session to-day of the Standards Committee considering the recommendations of the various divisions was brought about by the suggestion that the S. A. E. should depart from its usual practice and adopt a formula of engine rating as recommended practice. The question came up in connection with the tractor division report, particularly as regards the horsepower formula for tractor engines.

H. L. Horning expressed the view that the S. A. E., as an engineering body, should not depart from its precedents in this regard. He cited the action of the Society in not endorsing the A. L. A. M. formula and said he thought this was a question for the industry to solve, rather than this body. Dent Parrett gave notice of an appeal to the Society for action on the question, on the basis that the tractor division of the S. A. E. is the only technical body representing that industry.

John R. Cautley suggested that the committee do not pass the recommendation as a standard or as a recommended practice, but commend it to the manufacturers of tractors and stationary engines as a fair commercial rating. This met the approval of the committee.

The committee rejected only one recommendation, that of the tank and radiator cap. The suggestion made with the rejection was that S. A. E. threads be adopted if possible. J. J. Aull made this suggestion.

The remainder of the report of the miscellaneous divisions was approved with the comment that the drawing of the steering wheel hub was out of scale and should be revised.

Report of Divisions as Revised and Approved by Standards Committee

The standard battery ratings shall be established at a standard temperature of 80 deg. fahr.

The rated capacity of storage batteries for farm lighting service shall be based on a final voltage of not less than 1.75 volts per cell.

The period of elapsed time at which the rated ampere-hour capacity is available shall be definitely stated.

In rating farm lighting batteries, the maximum available capacity can be obtained intermittently, or over prolonged discharge periods shall be limited to that obtainable over a

NOTE:—The Terminals as Formed in Fig. 1. may also be Formed as shown in Fig. 2.
These Terminals are not intended for Use on Ignition Distributors.

Spade-type cable terminal for generators, switches and meters

period of 72 hours. The capacity which can be obtained over a continuous discharge period of 8 hours shall be stated.

The standard test shall be at a rate of 1/24 of the ampere-hour capacity of the battery for an initial period of 4 hours, followed by a 16-hour rest; and then by two 8-hour periods, each followed by a 16-hour rest. After the last rest the final discharge period shall be 4 hours.

Note: All of the above is applicable to nickel iron batteries, except the final voltage per cell, which applies to lead batteries only. The short periods at the beginning and at the end of the test permit it to begin at noon of the first day and end at noon of the last day.

Barrel Mounting of Starting Motors

The present recommended practice for barrel mounting of starting motors is revised in that definite limits for the gear location of the starting motor with respect to the flywheel are provided, a pitch line clearance of 0.015 to 0.025 in. instead of 0.015 in. being recommended.

Focusing Lengths of Incandescent Lamps

Tolerances are placed on the location of the filament within the bulb with respect to the lamp axis, as follows:

Deviation along axis of base .... ± 3/32 in.
Deviation at right angles to axis of base .... ± 5/64 in.

It is recommended that the above deviations be reduced by the incandescent lamp manufacturers so that the allowable deviation from the axis of the base is no greater than one-half of the base of the filament field for any type of incandescent lamp.

Lens Sizes

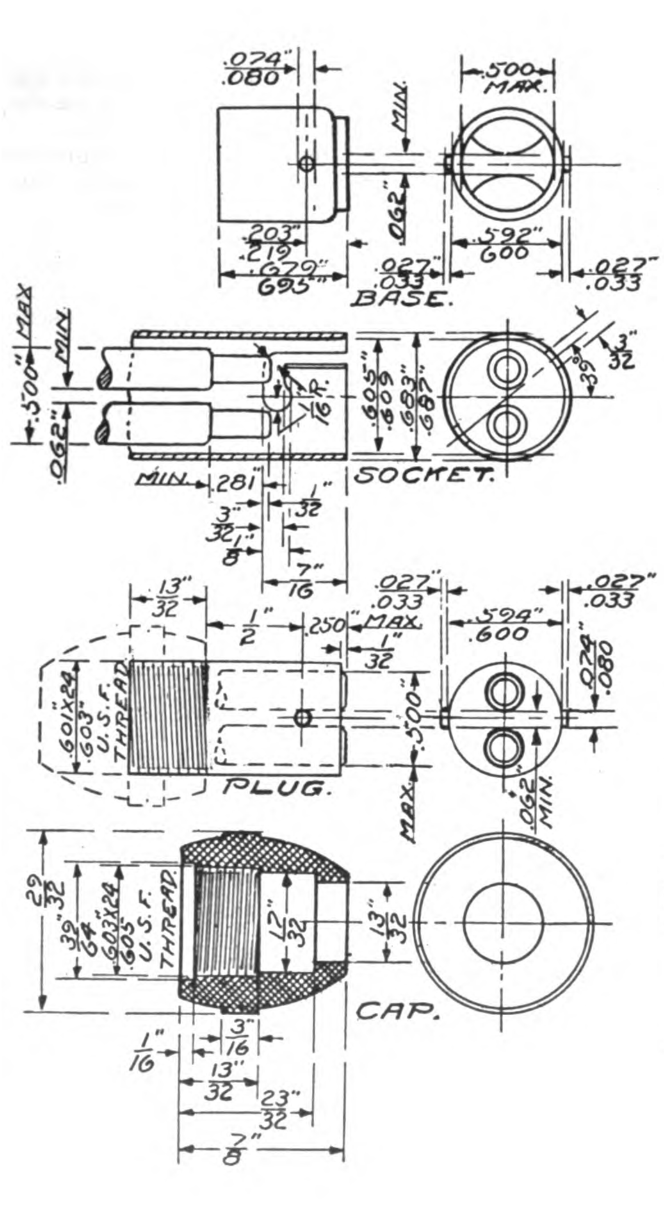
The following standard outside diameters and diameters of prism area are recommended:

Outside Diameter of Lens	Diameter of Prism Area
8⅛ + 1/32, — 0	6⅞ ± 1/32
8½ + 1/32, — 0	7¼ ± 1/32
9 + 1/32, — 0	7¾ ± 1/32
9½ + 1/32, — 0	8¼ ± 1/32

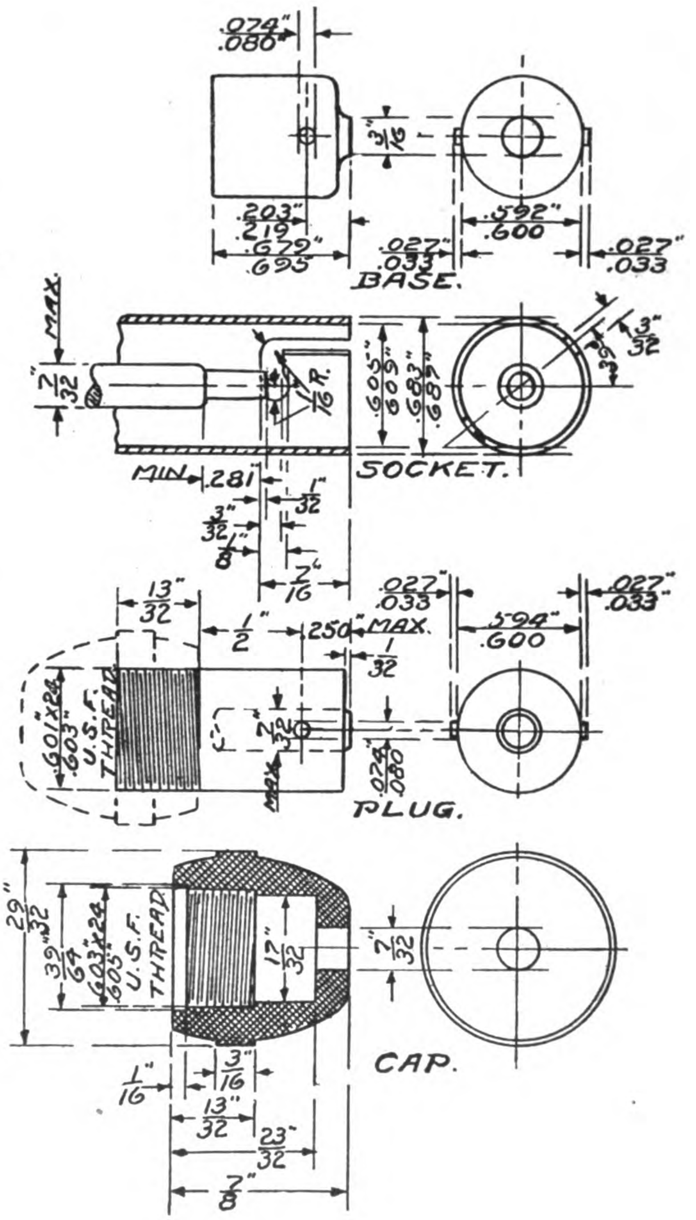
Thickness of bevel edge for all sizes is to be ⅛ in., plus 1/32, minus 0. This is commonly known as double thick American glass.

Bases, Sockets and Connectors

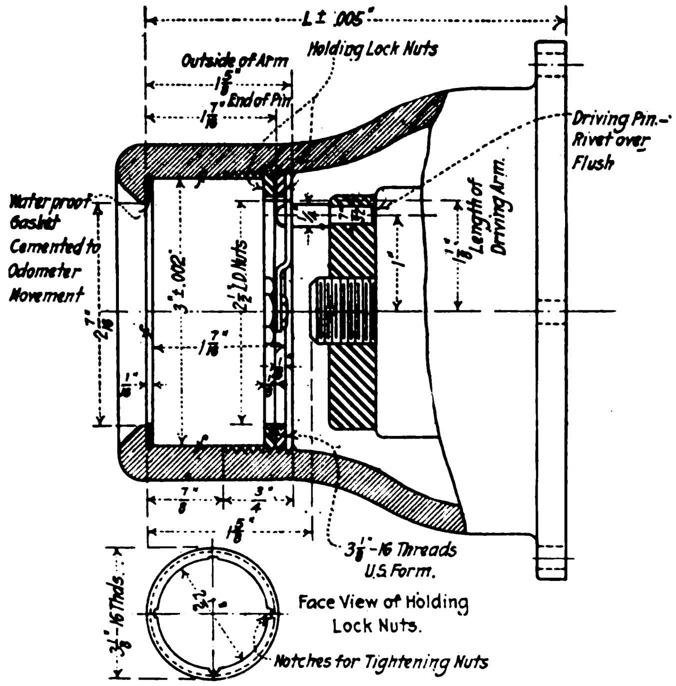
Revisions are recommended in the specifications for bases, sockets, plugs and caps for insulated- and ground-return sys-



Electric base, socket, plug and cap for insulated-return system



Electric base, socket, plug and cap for ground-return system



Hub odometer

tems, these revisions bringing the S. A. E. standards in line with present practice. The two accompanying cuts show the new standards.

Screw Stock

Two screw stock materials are recommended, both corresponding with specifications of the American Society for Testing materials. These are No. 1112, Bessemer screw stock, and No. 1120, open-hearth screw stock, these superseding No. 1114 S. A. E. specification, which included both Bessemer and open-hearth stock. These two steels are intended for general automatic screw machine products not requiring more particular properties.

S. A. E. Specification No.	Carbon	Manganese	Phosphorus	Sulphur
1112	0.08 to 0.16	0.60 to 0.80	0.09 to 0.13	0.075 to 0.15
1120	0.15 to 0.25	0.60 to 0.90	0.06 maximum	0.075 to 0.15

Chromium Steels

S. A. E. Specifications Nos. 5195, 51120 and 52120 are eliminated and the chromium limits of Specifications Nos. 5120, 5140 and 5165 are changed from 0.65 to 0.85 per cent with 0.75 per cent desired to 0.60 to 0.90 per cent with 0.75 per cent desired. Specification No. 5295 is replaced by Specification No. 52100 with the analysis given below. Steels that do not appear to be necessary are thus eliminated and replaced with one fully representative type of oil-quenching steel.

The S. A. E. Standard for chromium steels as thus revised by the Division is as follows:

	Carbon		Manganese				Chromium	
S. A. E. Specification No.	Minimum and Maximum	Desired	Minimum and Maximum	Desired	Phosphorus (Maximum)	Sulphur (Maximum)	Minimum and Maximum	Desired
5,120	0.15 to 0.25	0.20	*	*	0.04	0.045	0.60 to 0.90	0.75
5,140	0.35 to 0.45	0.40	*	*	0.04	0.045	0.60 to 0.90	0.75
5,165	0.60 to 0.70	0.65	*	*	0.04	0.045	0.60 to 0.90	0.75
52,100	0.95 to 1.10	1.00	0.20 to 0.50	0.35	0.03	0.03	1.20 to 1.50	1.35

*Two types of steel are available in this class, one with manganese 0.25 per cent to 0.50 per cent (0.35 per cent desired), and silicon not over 0.20 per cent; the other with manganese 0.60 per cent to 0.80 per cent (0.70 per cent desired), and silicon 0.15 per cent to 0.50 per cent.

Nickel-Chromium Steels

A change is to be made in the specification numbers, as follows:

Present Specification No. X3315 to be changed to No. 3415, No. X3335 to No. 3435, No. X3350 to No. 3450. The object of these changes is to obviate mistakes in telegraphic orders, etc.

Tungsten Steels

Two tungsten steel specifications, suitable for high tungsten steel for exhaust valves, are recommended, these corresponding to Signal Corps specifications W-60 and W-60-A. They are as follows:

	Carbon						
S. A. E. Specification No.	Minimum and Maximum	Desired	Manganese. Maximum	Phosphorus. Maximum	Sulphur. Maximum	Chromium	Tungsten
7060	0.50 to 0.70	0.60	0.30	0.035	0.035	3.00 to 4.00	12.00 to 15.00
7160	0.50 to 0.70	0.60	0.30	0.035	0.035	3.00 to 4.00	15.00 to 18.00

Hub Odometers for Trucks

It is recommended to standardize the housing dimensions as per the drawing below.

Steering Wheel Hub

The following table in connection with the dimension diagram gives the proposed steering wheel hub standards.

The nut dimensions in the table, which are submitted as general information only, allow for the proper seating of the nut on the pad (diameter F):

All Threads U. S. F.

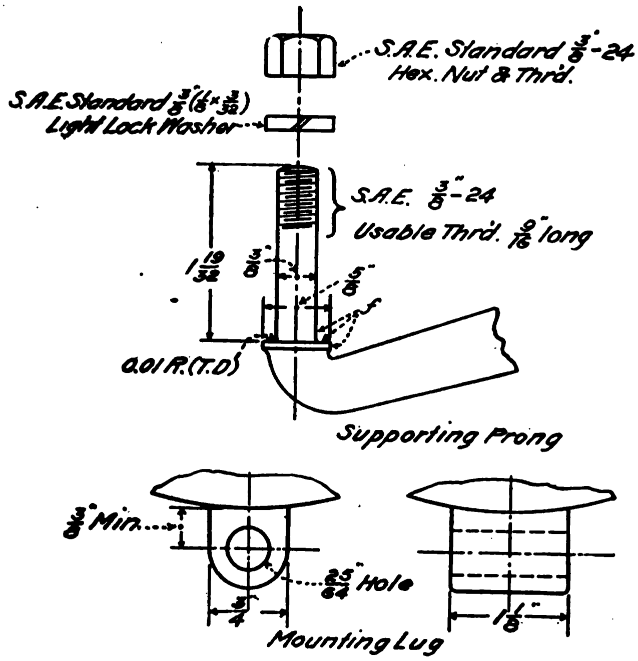
Steering wheel hub

Committee ruled drawing out of scale

Headlamp Mounting Lugs and Supporting Prongs

The following, which is established practice, is recommended as S. A. E. standard and to replace the present S. A. E. Recommended Practice on the subject:



Headlight mounting lugs
and rounded-edge taper holes

Motorcycle Chains

Motorcycle driving chains shall be of the roller type with the following dimensions: Pitch, ⅝ in.; roller width, ⅜ in.; roller diameter, 0.40 in.

Motorcycle Adoption of Existing S. A. E. Standards

The approval of the following existing S. A. E. standards and recommended practices for motorcycle practice is suggested:

Cotter pins, screws and bolts, screw threads, square broached fittings, taper fittings, 4-spline fitttings, taper fittings with castle nuts, steel specifications, babbitt metal, bearing metals, brass casting metals, cast manganese bronze, manganese bronze sheets and rods, hard cast bronze, gear bronze, aluminum alloys, brass sheets and strips, brass rods, Tobin bronze rods, non-ferrous metal tubing, nomenclature of roller-chain parts, roller chain dimensions, test specimens for iron and steel, cold-drawn seamless steel tubes, steel bands and strips, brake linings, annular ball bearings, light series; annular ball bearings, tolerances; electric bulbs oversize cylinders, piston-ring grooves.

Stationary Electric Engine Rating

The Tractor Division recommendation on nominal tractor engine ratings is proposed for adoption as S. A. E. standard for stationary engine practice.

Voltage and Capacity Ratings Electric Lighting Outfits

Farm lighting plant voltage and capacity ratings shall be according to the accompanying table.

Normal Ratings in K.W.	Nominal Voltage (16 cells)	Eng. and Gen. R.P.M. (Direct Coupled)
½	32	1200
¾	32	1200
1	32	1200
1½	32	1200
2	32	1200
3	32	1200
5	32	1200

S. A. E. Engine Testing Forms

The present S. A. E. Standard Engine Testing Forms are suitable for stationary engine work with certain additions and changes, as follows:

Sheet A—No additions or changes.

Sheet B—(a)—Addition of "Normal Horsepower" after "Name and Model."
(b)—Addition of "Normal R.P.M." as Item No. 2a.
(c)—Addition of the sub-division "Cooling System" after "Lubricating System" with the following items:
Air-Cooled .....Water-Cooled. { Radiator, Capacity, Gal....Lb...
Tank, Capacity, Gal....Lb...
Hopper, Capacity, Gal....Lb...
(d)—Addition of "Nominal Rated Horsepower" formula in Item No. 3:

$$\frac{0.7854\ D^2LRN}{13000}\ \ldots\ldots$$

Sheet C—Addition of "Weight of Water Evaporated" after "Temperature of Jacket Water-Out" under "Brake Horsepower and Fuel Consumption" and "Friction Horsepower" subdivisions.

Sheet D—Addition of R.P.M. ordinates from 0 to 1300 above that part of the present ordinates reading from 200 to 2800.

It is understood that these additions will be marked so as to refer to footnotes on all sheets reading "For use with stationary, gas and farm engines only."

Round Pipe Flanges for Stationary Farm Engines

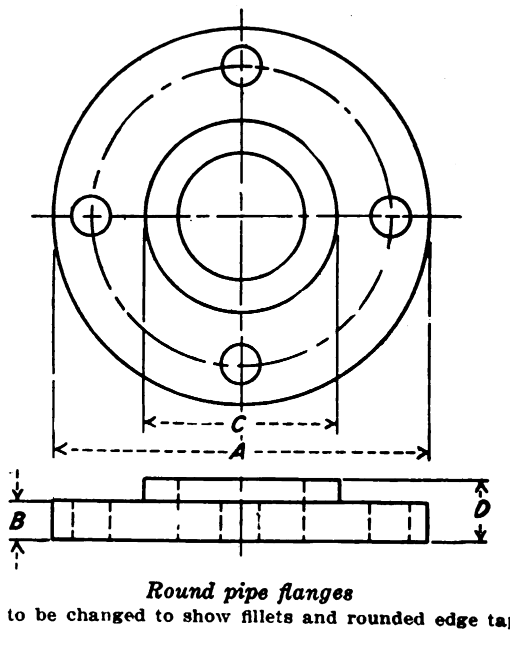
Size of Pipe in Inches	External Diameter, A	Thickness, B	Diameter of Hub, C	Length of Hub, D	Diameter of Bolt Circle	No. of Bolts	Size of Bolts
1	4	7/16	1 15/16	11/16	3	4	7/16
1¼	4½	½	2 5/16	¾	3⅜	4	7/16
1½	5	9/16	2⅝	⅞	3⅞	4	½
2	6	⅝	3⅛	1	4¾	4	⅝
2½	7	11/16	3⅝	1 1/16	5½	4	⅝
3	7½	¾	4 5/16	1⅛	6	4	⅝
3½	8½	13/16	4⅞	1 3/16	7	4	⅝
4	9	15/16	5⅜	1 3/16	7½	4	⅝
4½	9¼	15/16	5 13/16	1¼	7¾	8	¾
5	10	15/16	6 7/16	1 5/16	8½	8	¾
6	11	1	7 9/16	1 7/16	9½	8	¾

NOTE.—These dimensions conform with the A. S. M. E. and the American Manufacturers' Standard for 125-lb. American Standard Flanges.

Threads to be American Briggs Standards taper pipe threads (A. S. M. E. Sept. 17, 1913).

Motorcycle Spark Plug Shell

The ⅞-in. hexagon spark-plug shell and tapped hole dimensions and tolerances for the ⅞"-18 U. S. F. thread, are recommended for an S. A. E. motorcycle standard. As the tapped hole tolerances given are considered too wide for motorcycle practice, the following complete specifications for S. A. E. Recommended Practice are suggested:



Round pipe flanges
Drawing to be changed to show fillets and rounded edge taper hole

Spark Plug Thread Dimensions

Diameter	Maximum Mm.	Maximum Inch	Minimum Mm.	Minimum Inch
Outside (full)	....	0.709	....	0.706
Pitch (effective).....	....	0.670	....	0.667
Root (core)	....	0.626	....	0.623

Tapped Hole Dimensions

Diameter	Maximum Mm.	Maximum Inch	Minimum Mm.	Minimum Inch
Outside (full)	....	0.719	....	0.717
Pitch (effective) ...	....	0.674	....	0.672
Root (core)	....	0.636	....	0.634

These tolerances are now being specified and are suitable for standard, requiring only a little better grade of workmanship allowed in using the aeronautic tolerances.

Solid Tire Sizes

Inches	Mm.	Inches	Mm.
32x3	75/660	36x 6	150/762
32x3½	90/660	40x 6	150/864
34x3½	90/711	36x 7	176/762
36x3½	90/762	40x 7	175/864
32x4	100/660	36x 8	200/762
34x4	100/711	36x10	250/762
36x4	100/762	40x10	250/864
34x5	125/711	40x12	300/864
36x5	125/762	40x14	350/864
40x5	125/864		

NOTE—These tire sizes have already been adopted by N. A. C. C. and the Rubber Association of America.

Solid Tires for Single and Dual Wheels

The following definite front and rear wheel application of the proposed solid tire sizes is recommended as supplementary to the proposed standard:

Tires for single wheels		Tires for dual wheels		
32x3	36x4	36x4	36x 8	(Single tire fits 36x4 dual wheel)
32x3½	34x5	36x5	36x10	(Single tire fits 36x5 dual wheel)
34x3½	36x5	40x5	40x10	(Single tire fits 40x5 dual wheel)
36x3½	36x6	40x6	40x12	(Single tire fits 40x6 dual wheel)
32x4	36x7	40x7	40x14	(Single tire fits 40x7 dual wheel)
34x4				

Carrying Capacity of Solid Tires

Solid tire width	Up to and including 36 in. diameter	40 in. diameter
3	1000	....
3½	1300	....
4	1700	....
5	2500	2600
6	3300	3500
7	4200	4500

6	27/32	6⅞	±1/32	7/16	32	0.185	5 59/64	6 1/16	9/128
7	27/32	7⅞	±1/32	7/16	36	0.192	6 59/64	7 1/16	9/128
8	⅞	8⅞	±3/64	7/16	40	0.196	7 27/32	8	5/64
10	⅞	10⅞	±3/64	7/16	50	0.196	9 27/32	10	5/64
12	⅞	12⅞	±3/64	7/16	60	0.197	11 27/32	12	5/64
14	⅞	14⅞	±3/64	7/16	70	0.197	13 27/32	14	5/64

NOTE.—The above values correspond to those adopted by the War Service Committee of the Rubber Industry of the U. S. A.
*Either mill corrugated or dovetail facings may be used.

Solid Tire Sections

The 3-in. solid tire sectional area is to be included in the present standard so that it will conform to the proposed solid tire standard.

Solid tire widths, in.	*Minimum total sectional area or rubber, sq. in.
3	....
3½	6.75
4	7.75
5	10.75
6	13.75
7	16.75
8	19.75
10	25.75
12	31.75
14	37.75

*Includes both hard and soft rubber.
NOTE—The above values correspond to those adopted by the Solid Tire Division, War Service Committee of the Rubber Industry of the U. S. A.

Section Dimensions of Single and Dual Solid Tire Wheels

The steel band thickness for the felloe bands for the 3½ and 4-in tires be changed from ¼ to 5/16 inches.

Pneumatic Tires and Rims for Passenger Cars and Commercial Vehicles

Nominal tire and rim sizes Inches	Mm.	Oversize tire Inches	Mm.	Tire-seat dia. (rim) Inches	Mm.	Type of rim

Power Take-Off

The Truck Standards Division recommended for adoption as S. A. E. Recommended Practice for Power Take-Off the recommendation of the Transmission Division on Tire-Pump Mounting.

Referred Back to Sub-Committee

Nominal Tractor Engine Rating

$$\text{Nominal rated horsepower} = \frac{0.7854D^2LRN}{13{,}000} \quad \text{where}$$

D = piston diameter in inches
L = stroke in inches
R = r.p.m. of crankshaft
N = number of cylinders.

Nominal Tractor Draw Bar Rating

The tractor drawbar rating shall be 50 per cent of the tractor engine (belt) horsepower rating.

If desired, this may be expressed

$$\text{Drawbar rating} = \frac{0.7854\ D^2LRN}{26{,}000}$$

$$\text{Drawbar pull, lb.} = \frac{\text{Rated drawbar horsepower} \times 375}{\text{miles per hour}}$$

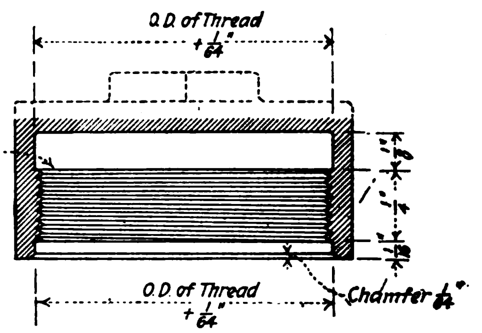
*These data are submitted as general information only as representing good present-day practice.
All pneumatic tires to be of cord construction.

Rejected by Committee

Use of S. A. E. Threads Suggested

Tank and Radiator Caps

Fifteen diameters, all having the same screw pitch, 16 U. S. F., are proposed for standardization, the diameters being, 1, 1⅛, 1¼, 1⅜, 1½, 1⅝, 1¾, 1⅞, 2, 2¼, 2½, 2¾, 3, 3½ and 4 in.



Tank and radiator cap

Testing Motorcycle Engines

IN the British motorcycle factory of J. A. Prestwich & Co., Ltd., all engines are given a fan dynamometer test. After the engine has been clamped in position on the test stand by means of two bolts, a chain is fitted on the sprocket wheel on the camshaft from a magneto on an adjustable bed, and the bed is adjusted to give the correct tension to the chain. The gasoline and exhaust pipes are then coupled up to the exhaust pipe leading into a main behind the bed. The final operation is to couple up a Walker fan brake and the starting gear.

How Germans Raided a Belgian Automotive Factory

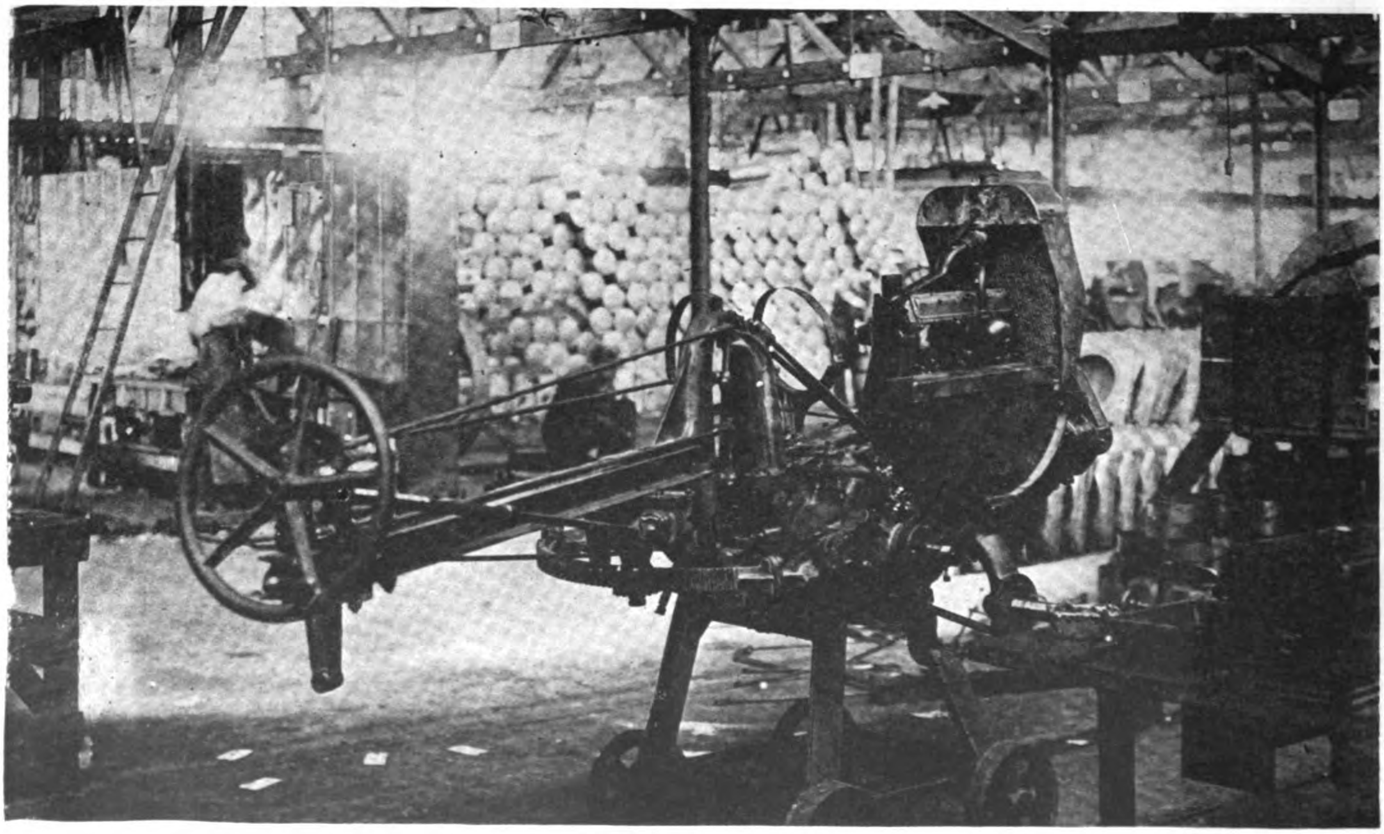
Beginning of the transmission assembly line



Primary assembly nearly completed

Putting the Human Element Into a Tractor Assembly Plan

LAST week Mr. Heldt told how the Moline tractor was produced. This week he tells how it is assembled. There is a thoroughness about the system that suggests an older industry; but, best of all, in two points the human elements are considered—first, in the pay of the men; second, in the daily conferences of the men responsible for the tractor.

By P. M. Heldt

IN assembling the Moline tractor, first comes the transmission housing, which is placed on a transport truck, made up of two castings, which are bolted together by means of three heavy steel bars. These transport trucks are fitted with four metal wheels, and are of such design that the transmission housing fits to them exactly. The wheels run on the cement floor between guide rails, hence the trucks keep absolutely in line.

In putting in cap screws, use is made of a speed wrench, which consists of a socket wrench with a large flywheel. This flywheel is set to spinning and not only turns the screw to place, but also draws it up with the requisite force.

Along the line on which the assembly transport trucks move there are benches, especially designed, to hold the parts that go onto the tractor. Back of these benches there are so-called substations, where small assemblies are made up before they are put on the main assembly.

All assembly work is done on the piece price system. That is to say, a certain sum is paid for assembling each tractor, and the amount due for assembling each week is equally divided among the men engaged in this work. The object of this system is co-operation. While the work is divided among the different operatives as nearly equally as possible, it is impossible to prevent some of the men running behind occasionally with their jobs, and

under this system they will be helped by their "neighbors," so that all keep busy at all times.

The engines and radiators are put on the main assembly at the end of the first assembly line, the engines being conveyed to the line by means of a monorail trolley system.

All engines are thoroughly tested before they are put into tractors, and quite a large testing room is required. At the time of the writer's visit, a considerable addition to the test room was under way, to allow for the increase in production contemplated. At that time there were 39 stands for engine tests in the room. Coal gas is used for making these tests instead of gasoline. The whole scheme of the test room is well worked out, and the latter presents a comparatively clean appearance, being free from the multitude of pipes, wires, etc., which one generally finds in a test room laid down without any prearranged plan.

The water and fuel pipes lie in a trench at the front of the stands, and there is a storage battery back of each stand. Only two pipe connections are required, one for water and one for gas, as the water, after leaving the engine jacket, runs into a trench centrally below the stand, whence it drains into the sewer pipe. There are two kinds of stands in the testing room, one for running in the engines, the other for testing them under power. The engines are started by means of a portable electric motor.

All of the painting is done by means of the air spray. The tractor unit, on its transport truck, stands in the forward part of a spray booth, in the rear of which there is an electrically driven exhaust fan, which draws the excess paint and varnish out through a stack. Two coats of paint and one of varnish are applied.

Owing to the enormous amount of storage space required for air drying, the company, at the time of the writer's call, was installing an oven-drying system, with continuous chain conveyor.

After the tractors have passed through the paint department, they go into the final assembly, alongside of which there is a large stockroom in which are kept such parts as generators, motors, gasoline tanks, strap bolts, nuts, electric wiring, searchlights, battery boxes, carbureters, drive wheels, etc.

The tractors are taken off the paint line into the final assembly. Here are 15 stations. At each of these stations certain parts are added, and then the machine, on its wheeled truck, is moved on to the next station. One of the interesting features of the final assembly department is an arrangement whereby the cooling systems of the tractors can be filled without the use of a floor hose, which is usually very short-lived because of the way in which it is handled, and the use of which is generally accompanied by considerable slopping. A water tank is built on a rafter above the point where the assembly work is completed, and is provided with a flushing valve, so made that when a string is pulled an amount of water exactly sufficient to fill the cooling system is released. The tank, of course, refills automatically.

In one corner of the building, housing the final assembly department, there is a battery room 50 x 60 ft. Among the equipment of this department may be mentioned a water-distilling apparatus which has a capacity of ½ gal. per hr., and a 25-kw. motor-generator set for transforming the charging current. The batteries used on the Moline tractor are of the 6-volt type, and 13 batteries are connected in series for charging in the battery room. All batteries arrive at the plant from the battery makers in the dry state.

After the wheels have been put on the tractor the latter is removed from the transport truck by means of an air hoist, and it is then taken over to the test shed. Here each tractor is given a 5-hr. test under its own power, on a special design of test block. These test blocks are of cast iron and are provided with a wood lining, on which the engine of the tractor slips the wheels. On the opposite side of the building the tractors, after the tests have been completed, receive their final inspection and are tagged.

A noteworthy feature of the organization is the dining room for department foremen and factory heads, in a dwelling adjacent to the plant. It is operated by the company. Here all of the department foremen and factory heads take lunch every day, for which there is no charge. The departments represented here are engineering, accounting and inspection. Among the problems discussed at these gatherings are those pertaining to manufacture, discipline and policy, complaints from customers, difficulties met with in inspection, contemplated shop alterations and improvements, tooling and methods. Topics discussed but not disposed of at one meeting are carried over to the next day. These meetings are presided over by Mr. Keith, the factory superintendent, who calls upon the different foremen to report on subjects pertaining to their respective departments, or on subjects which have been assigned to them.

Gluing Veneer at High Moisture Contents

It is common practice among plywood manufacturers to dry veneer down to very low moisture contents before gluing it. The object in doing so apparently is to prevent shrinkage of the veneer and consequent marring of the appearance of the finished panel. The drying is done in plate redriers, textile driers or similar apparatus, and adds appreciably to the cost of manufacturing panels.

That such preliminary drying may not be necessary is indicated by the results of a recent investigation by the Forest Products Laboratory. Veneer panels were glued with casein glue at various high moisture contents (some over 50 per cent), and in various tests proved as strong and as desirable as those made under drier conditions. In fact, in the moisture resistance tests a considerable proportion of the veneer which had been dried before gluing showed signs of failure, whereas veneer glued at a moisture content of 15 per cent or higher gave practically perfect results. Panels made at high moisture contents checked if dried too rapidly, but this difficulty could be avoided by proper operation of the kiln.

It seems possible, therefore, that the cost of producing panels of certain kinds may be very materially lessened through the use of water resistant glue and the reduction or even elimination of preliminary drying. Very dry veneer is more likely to break or split than damp veneer; an additional saving is therefore possible through a reduction of waste.

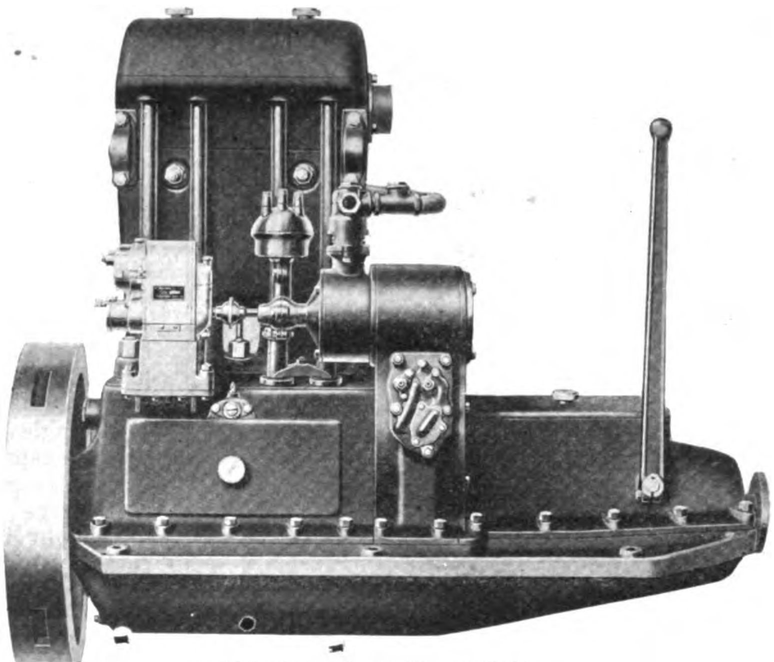
The use of moist veneer, of course, is not practicable for some purposes, but it is quite certain that much of the veneer which is now being painstakingly dried before gluing might advantageously be glued at a higher moisture content.

Novel Features in a Two-Cylinder Marine Set

Engine Is Combined with Reverse Gear in a Single Unit—Complete Inclosure of the Working Parts—Heavy Combustion—Force Feed Lubrication—Bilge Pump, Which Can Be Used as Cooling Water Pump, Is Supplied Extra

A TWO-CYLINDER marine set, comprising an engine and a reverse gear in one unit, is an interesting development. All the components of this set are of very substantial dimensions, and the engine is capable of working steadily under full load. The cylinders are of 5-in. bore and 8-in. stroke, and the engine is rated at 12 hp. at 400 r.p.m. and 25 hp. at 800 r.p.m.

The valve-in-head form of construction is used, which is generally associated with maximum power and fuel economy. One other advantage of this construction is that the entire compression chamber can be machined all over. The two cylinders are made in one casting of vanadium gray iron, and are heat-treated and seasoned. Heavy holding down lugs are cast on the cylinder block, and the studs for these lugs are screwed into substantial bosses in the upper half of the crankcase.



Trego marine unit complete

Both sets of valves are mechanically operated through tappet rods and rock levers, and the entire valve mechanism is completely inclosed and automatically lubricated. The cam followers are of the roller type, and there are long bearing surfaces in the push rod guides, which latter are secured to the crankcase by means of crow-foot clamps. The tappet rods are provided with ball and socket connections at both ends, and there is a simple and accessible adjustment at the upper end.

The entire valve mechanism is lubricated by oil under pressure from the main reservoir, which is forced through the hollow rocker arm shaft to the center of each rocker arm bushing. The surplus oil from these bearings lubricates the springs and other parts, and then returns to the engine base through the tappet rod tube and push rod guide, thus also lubricating these parts. The lubricating oil is carried in a tank separate from the engine, which permits of carrying a larger amount of oil than has been customary in marine installations. This tank is provided with a gage showing the amount of oil it contains. The tank can be filled or drained without disturbing the oil lines or other fittings. The surplus oil, accumulating in the crankcase bottom, is returned by a separate pump to the tank, and all oil is strained three times while making one complete circuit.

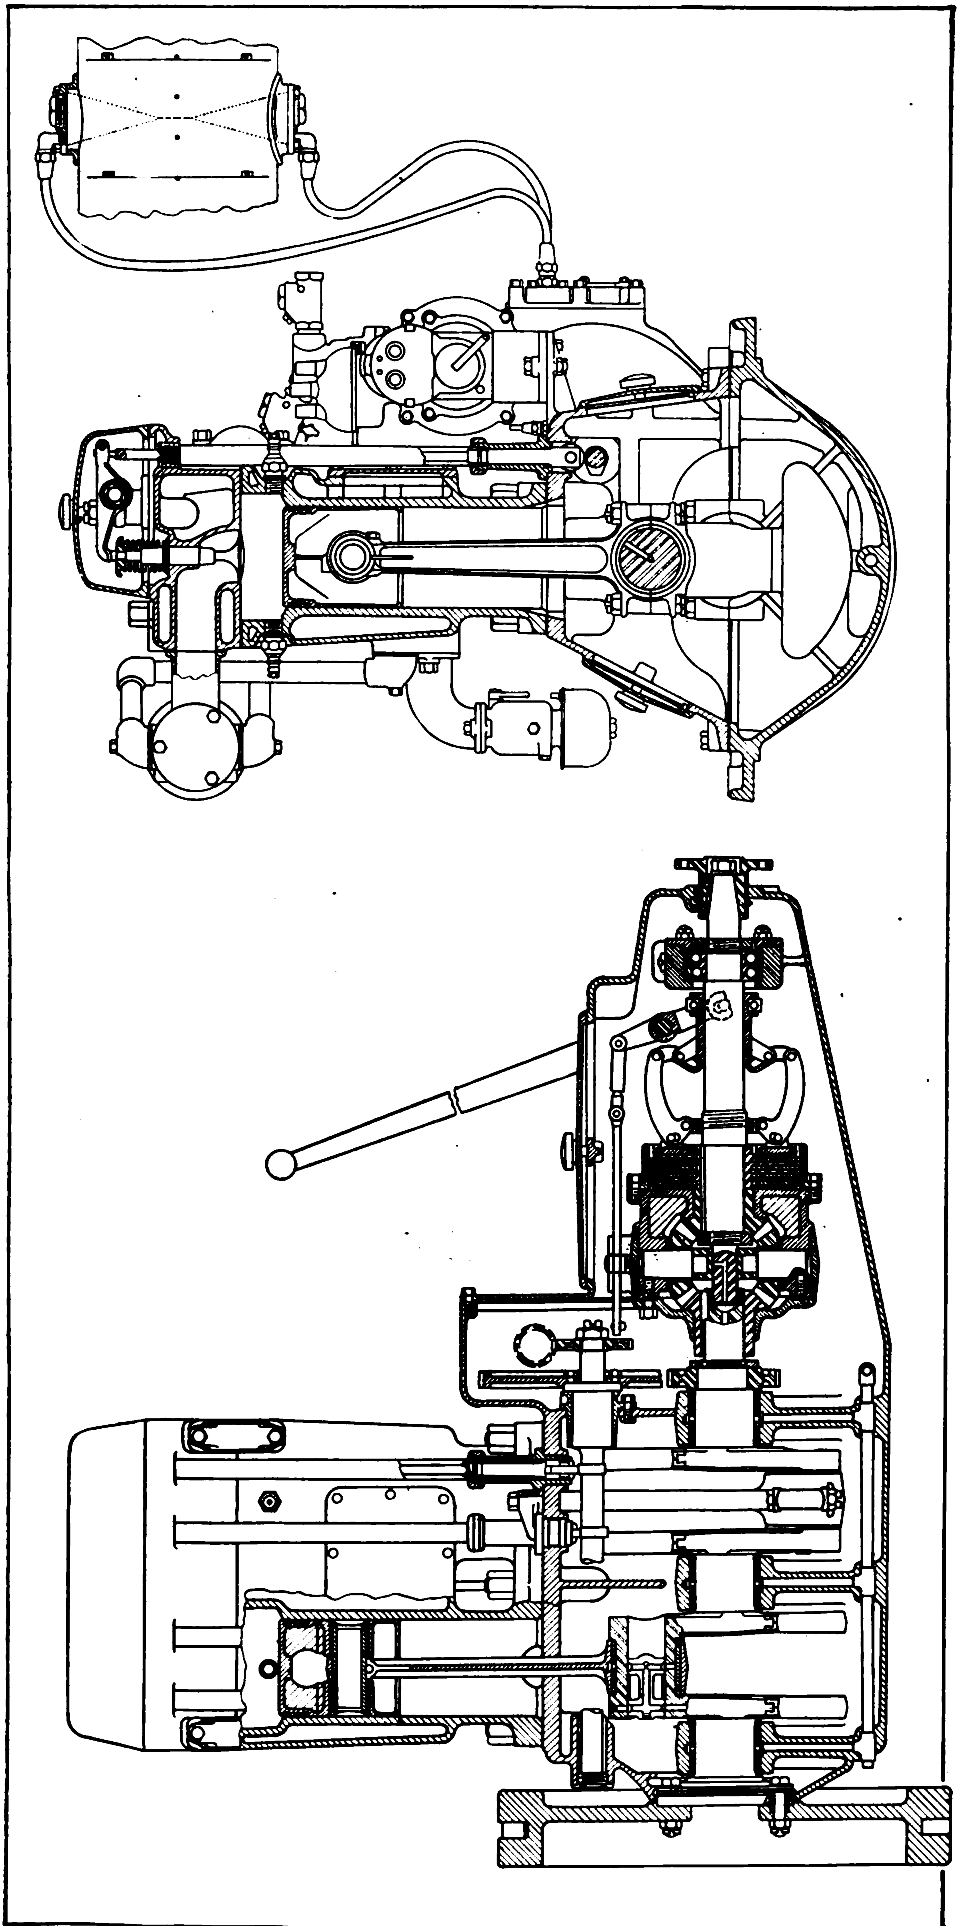
Force feed is used for the main and crankpin bearings, the reverse gear and the valve-operating mechanism, the pressure of feed being regulated by means of an adjustable by-pass valve. Cylinders, camshaft bearings and gears, distributor shafts and gears, water pump and accessories are lubricated by spray from the crankpin bearings. In addition to the main oil pump, which feeds oil under pressure to the main bearings, there is an auxiliary pump, which returns the surplus oil to the tank, and both pumps are combined in one assembly and can be instantly removed. An oil pressure gage, adapted to be mounted on the steering wheel, is furnished with the set.

The cylinder head is removable, which obviates the necessity for valve cages, and insures more thorough cooling of the valve seats. Cooling water is carried from the cylinder jacket to the head jacket through by-passes bolted to the sides of the cylinder blocks. This obviates the necessity for ports in the cylinder head gasket. The cast iron exhaust manifold is fully water jacketed. The inlet pipe is inclosed within the cylinder blocks, whereby a uniform temperature of the mixture entering the cylinder is insured for all seasons of the year. A kerosene attachment, which is said to give very satisfactory results, can be supplied as an extra.

There is a large hand hole on the water jacket, which permits of cleaning out the jacket and also serves to prevent injury to the cylinder castings by a freeze up, as the cover plate is of light material.

Before entering the cylinder jacket the cooling water is circulated through the jacket of the exhaust manifold, thereby greatly reducing the volume of the exhaust gases, and cutting down back pressure and noise.

A bronze plunger-type water pump is employed, the working parts of which are fully inclosed and lubricated



Longitudinal sectional view and cross-section of Trego marine unit

by splash, a dipper on the eccentric shaft dipping in the oil.

As an extra, the Trego Motors Corp., the manufacturer, also makes a bilge pump, which is a duplicate of the cooling water pump, and can be used for the purpose of the latter in an emergency. This bilge pump is provided with a clutch, operated by a hand button, and therefore operates only when required. All water piping is of brass, and all connections are of the flange and bolted type, the water inlet and outlet being both ¾-in. pipe sizes.

The pistons are made of gray iron castings, with 8 radial ribs inside, designed to distribute the heat. Three piston rings are fitted above the piston pins, and there are also a number of oil grooves on the piston. The piston pin, which is 1¼ in. in diameter, is made of steel, hardened and ground; it is securely locked in the connecting rod, and rocks in two bronze bushings secured in the piston bosses. Each bushing has an effective bearing length of 1 9/16 in. There are oil pockets in the piston bosses over the bearings. Conventional drop forged I-section connecting rods are used. The crankshaft is of very substantial design, and is fully counter-balanced. All main and crankpin bearings are of bronze, babbitt-lined, the dimensions of each bearing being 3 x 3 in.

Two sizes and weights of flywheel are furnished, 19½ in. and 23 in. in diameter respectively. These wheels are bolted to an integral flange on the crankshaft, the bolt passing through hardened steel dowels. The flywheel is located at the forward end of the power unit.

A single camshaft is used, which has the cams forged integral with it. The bearings of this camshaft are of extra large size, and are lubricated by oil caught in pockets directly above them. Gears with helical teeth are used for driving the camshaft.

There are large hand holes in the upper half of the crankcase. The latter is made of gray iron. The handhole plates are held in place by thumb nuts and are easily removed, whereupon access may be had to the main and crankpin bearings.

The lower half of the crankcase, which is made in one piece with the reverse gear extension, is also of gray iron. This casting is provided with a strong projecting ledge on either side, provided with heavy bosses for holding down bolts, and arranged with an oil trough to insure cleanliness. The crankcase is so designed that the bed timbers can be carried continuously from the bow to the stern, without interfering with the flyweel, except that when the 23-in. flywheel is used the bed timbers must be notched.

The reversing gear is of the Trego company's own design, and is of the bevel-gear type, employing heat-treated nickel steel gears. The tail shaft telescopes into the crankshaft, the latter being provided with a bronze bushing.

A multiple disk type of clutch is used, and is provided with a single nut adjustment and positive lock. The clutch is thrown in and out by a hand lever fitted to the outer end of a cross shaft. The entire reverse gear is completely inclosed, and runs in oil, which is forced outward from the center of the bearing by means of the oil pressure pump. There is a large handhole plate on the reverse gear housing, which can be instantly removed by unscrewing a single pump nut.

A double-thrust ball bearing is mounted inside the reverse gear housing, and runs in oil. There is a forged steel coupling with male and female members at the rear end of the reverse gear.

A standard float-feed carbureter is fitted, and the engine is furnished with two independent ignition systems, a high-tension inclosed waterproof type magneto and a battery system provided with waterproof boot. There are two spark plugs in each cylinder head, in water-cooled bosses.

Lively Discussion of Dr. Pogue's Fuel Paper

(*Continued from page* 1431)

to specify the b.t.u. per cubic foot, rather than the candle hours, is coming into use.

Road oil, which has been used in large quantities to lay dust, also contains some of the lighter fractions suitable for motor fuel.

How much fuel is wasted by incomplete combustion was illustrated by the remark that there had been cases in which forty per cent dilution had been found in crankcase oil after 200 miles driving.

Taking up Hinkley's request for the stabilization of fuel characteristics, Dr. Pogue said the situation was similar to that of a naval gunner who said he could make a hit all right if his own ship could be stopped and the enemy ship, forming the target, could also be compelled to stop. Fuel will always change and automotive engineers will have to shoot from a moving base at a moving mark.

Hugo Gibson suggested that if the fuel research committee has any funds at its disposal, it should set aside a certain sum for the development of a device for producing a combustible gas from the heavier hydrocarbons. He pointed out that the heavy fuels must be heated slowly and must not be over-heated, and this would call for the use of a thermostat to by-pass any excess heat.

Mr. Horning, who said he had attended every meeting of the fuel research committee, informed the meeting that the committee would be able to tell the character of the fuel to be marketed a year or two in advance. He depreciated the policy of furnishing alarming statements regarding an impending fuel shortage to the press.

First, because there was no ground for alarm during the present generation;

Second, because we are just beginning to apply remedial measures which may change the situation.

He said the only thing the public should be told was to use fuel economically.

Fuel Problem Prominent in the Truck Discussion

(*Continued from page* 1435)

The discussion was opened by H. L. Horning, general manager of the Waukesh Motor Co., who told of some experiments made to improve the fuel economy of a certain 5-ton truck. This truck was loaded to 8 tons and then run at a speed of 18 m.p.h. "to stimulate normal operating conditions," Mr. Horning said, jestingly, over a stretch of road 16⅛ miles, containing various classes of pavements and hills up to 9 per cent.

On the first trip 8 miles of gasoline were consumed. After some adjustment of the carbureter were made the run was repeated and the gasoline consumption reduced to 7 gallons. The truck had been fitted with a vacuum fuel feed and this was eliminated. Another saving of fuel was made on the next trip. Next a combination manifold was applied, which heated the charge, and this resulted in cutting the fuel consumption down to 5½ gallons. The fuel tank in the last experiment was located rather high and by bringing it to a lower lever this fuel consumption was reduced to 5 gallons 1 pint which was improved to 5 gallons ½ pint by very close adjustment of the carbureter.

Next the compression was lowered to sixty pound and kerosene was used as fuel 5 gallon 1½ pint being consumed on the 16⅛ mile run.

Mr. Hale of the Goodyear Tire & Rubber Co., gave some information on that company's experience with pneumatic tired trucks. They usually put a 5-ton truck power plant into a 3½-ton truck. This had a bearing on the formula presented in Mr. Kalb's paper and Mr. Hale counseled truck designers that, whatever results were arrived at by formula, they should be checked by comparison with practical results. The Goodyear Company has 5 trucks running without a differential on the rear axle and, although they have been in service for quite some time, no difference was noted in tire wear as compared with trucks having a differential.

Asked by Joseph Husson regarding the tire mileage obtained with the Goodyear company's pneumatic tired-trucks in service between Akron and Boston, Mr. Hale said that while he could give no definite figures the mileage was not very satisfactory, was due to the fact that the trucks were driven night and day by alternate drivers and the 750-mile trip was made practically without stop.

In the Canton-Cleveland service, where the roads are well paved and there are no hills, a mileage of 10,000 to 12,000 is obtained from 10-inch tires, which are still in the development stage and 15,000 to 20,000 from eight-inch tires. The company uses a 2-ton truck equipped with a 3½-ton power plant and pneumatic tires and loads it to 3½ tons.

Going to Advertise Abroad? Practice on Cuba

IN THESE days when so many American firms are trying their wings at export business there are many experiments to be tried. Our goods first went abroad because the other countries needed them? Now we have competition. If our merchants are to hold the trade against the before-the-war favorites they must advertise and create a demand.

This is an experiment which each merchant must try for himself. Here is some helpful advice, with the main facts set forth.

CUBA is a fine place to try out an export selling advertising campaign. Advertising abroad is a new field for a good many American firms and most of those who go into it will have to learn by experience. There are a number of reasons why Cuba may be the laboratory for this experiment.

One point, the Island is comparatively small and a campaign will not be as expensive as in larger countries. Another reason is that the Cubans are friendly and a mistake will not be as disastrous as in more critical countries. Finally, there are considerable data to guide the advertiser in Cuba.

So now, while European markets are practically closed to our automotive merchandise, the manufacturers must look elsewhere for an export market. Naturally they turn to Latin-America, where the first task is to create an American market of the demand that once was supplied by European manufacturers. This must be done by advertising. The Latin-American countries do not regard advertising as this country does, so the advertiser must learn new ways.

Cuba is essentially a Latin-American country. It is the nearest and the most friendly. It is more accustomed to American ways. So why not get the experience there?

Preparation for Campaign

But an advertising campaign in Cuba—or any other country—must not be undertaken without preparation. Unless complete investigation precedes the advertising, the money will be a waste. The value of Cuba as the "tryout" for American advertising to Latin America and the methods for such advertising are described at length by Trade Commissioner J. W. Sanger of the Bureau of Foreign and Domestic Commerce, Department of Commerce, in a bulletin describing advertising methods in Cuba. This pamphlet is the first of a series which will deal generally with advertising in all of the important Latin-American countries.

In his general description of the Cuban market, Mr. Sanger points out that the language of the island is Spanish and a knowledge of Spanish is essential for the transaction of general business, although many business men understand English and the latter language is taught in the schools.

Cuba is on a gold standard basis and its monetary system is modeled on that of the United States. The metric system is in general use, but other units are common. Postage rates between Cuba and this country are the same as our domestic postage. Mail distribution is prompt and the remote districts are reached by reasonably good service. Telegraph and telephone lines operate comprehensively. The population of Havana, which is the most important business center, is 95 per cent Latin and 75 per cent of its total business is in the hands of Spaniards.

American influence and business practices are gaining an increasing grip here, but business is generally conducted in a small way and is basically Latin in organization. Fixed prices are the exception and generally the price paid depends on the patience and shrewdness of the shopper.

The daily papers published in Havana are, practically speaking, the only island-wide media for news and advertising, says Mr. Sanger. There are no weeklies or monthlies similar to the American publications. The dailies carry considerable Cuban advertising, often crude and not always in good taste or truthful. Few American trade marks are known. No goods are asked for by name or brand, nor are prices displayed or advertised.

The leading merchants of Havana are almost unanimously of the opinion that the "bargain sales" methods of the United States would be useless in Cuba. They assert that native women, particularly, are not careful buyers. The natives buy for to-day and disregard to-morrow. Consequently offering of a quantity at a reduced prices does not appeal to them, because they can't use the increased quantity at one time. The Cuban woman is not the head of her home, as is the American woman.

Advertising in the Island comprises copy for the trade and for the consumer. The demarkation between the two is not always clear. Mr. Sanger found that consumer advertising frequently brings increase from the trade and vice versa.

American Export Journals

The use of American export journals printed in Spanish is approved by Mr. Sanger, who says that when these publications gain the proper standing they are used by the Cuban dealers as catalogs. Many manufacturers who have never had personal representation in foreign fields have received orders from advertisements in export journals. Because a number of export journals are of a questionable character, he suggests that advertisers should first inquire into the circulation of each issue in each Spanish speaking country, method of obtaining circulation, class of readers, affiliation with the Audit Bureau of Circulations, if

papers are sent in bulk or individually, source of the editorials and news articles, and if "write-ups" are permitted in the editorial pages, before buying space.

Personal letters, folders, small catalogs, etc., are freely used throughout the Island, not only as a means of reinforcing campaigns, but often as the main substance of the campaign itself. Sales letters from America should have the appearance of being written individually, must be courteous and friendly, yet should not take on that degree of familiarity used in this country. Familiarity implies lack of dignity and an ignorance of the proprieties to the Latin American. The letters should be signed individually and the higher the title of the signer the better. Under no circumstances should letters be marked, "dictated but not read," or "signed in the absence of."

Properly prepared catalogs have a value that scarcely can be overestimated in creating prospects, preparing the ground for salesmen and for aiding merchants to duplicate their orders. American merchants have used catalogs in Cuba successfully. A courteous, personal letter in the same mail with the catalog is important and aids a friendly reception. Not only Spanish, but idiomatic Spanish, should be used, and not the "so-called correspondence school Spanish," which Mr. Sanger states the Latin American "politely endures." Single catalogs sent by mail are not subject to customs duties, but printed matter in bulk, intended for distribution by the dealer, must pay Cuban tariff.

Havana daily newspapers are equal, mechanically, to American papers. Both the daily and Sunday editions are excellent mediums. They are well edited and compare favorably in appearance and text with papers published in the same size cities in the United States. The explanatory word "advertisement" is not required by law at the bottom of advertising reading notices, neither is a distinctive type used and, as a consequence, many papers carry paid items disguised as news. Cuban papers are willing to carry free publicity in connection with advertising.

The population of Havana is 400,000 and should support two morning and two evening papers, whereas thirteen dailies struggle for the circulation among a limited number of readers. The best papers in Havana, according to Mr. Sanger, are the El Mundo, Diario de la Marina, La Discusion, La Lucha and Heraldo de Cuba. These five dailies fairly well cover Havana, which means that they cover Cuba.

Copy Adapted to Conditions

Cuban copy must be written to conform to the Island idioms. It must be pictorial and it must portray enjoyment of emotions whenever possible. The "common sense copy" or the "reason why copy," common in the United States, finds little response in Cuba, excepting in the advertising of articles distinctly technical in nature. Cuban women do not read newspapers and take small part in home, club, civic or national affairs.

The necessity for giving full consideration to climate and social conditions is emphasized by Mr. Sanger, who cites, for example, the advertisement of an American manufacturer of cleaning wax for automobiles, in which the illustration pictured the man of the house and his wife deeply interested in cleaning their car. In Cuba, the work is done by the chauffeur or in a public garage. Even the cheapest automobiles are driven by chauffeurs, and the owner exerts no appreciable influence as to the kind of cleaning fluid or polishing wax used.

The free and easy, friendly and intimate copy much used in American advertising would be misunderstood and, in fact, regarded as impudent in Cuba. It is also well to remember, states the bulletin, that "United States" is preferable to the use of America or American, because America frequently means all of the two continents in the Latin-American countries. Coined words used as trademarks or trade names are not always advisable. They may be unpronounceable in Spanish or have a distinctly unfortunate meaning.

The Cuban has an almost Oriental tendency to speak and act indirectly. He talks and writes at great length. He will never make a plain answer of "No." His method is more courteous and roundabout. His tendency is not to be scientific or mechanical. He is less analytical than the Anglo-Saxon, and more easily impressed by an attractive picture. He is impressionable and likely to act on impressions; consequently a picture or illustration, indirect and simple, unhampered by technical arguments or "reason why" copy, is the surest to appeal to him.

Methods of placing advertising in Cuba vary. It can be done through Havana advertising agencies, through the local sales agents or dealers, or through United States advertising agencies. The latter has been found the best by Mr. Sanger. Advertising through local dealers is likely to produce waste. As a rule the dealers have no knowledge of advertising practice. The advantage of dealing through the Havana agency includes translation, placing of business, check of insertions, adjusting differences between publishers and advertisers and final settlement. These agencies, however, make no effort to analyze American conditions nor give the valuable co-operation extended by American advertising agencies. The more progressive American agencies have thoroughly analyzed the Cuban market, employ men who not only speak Spanish but know the Cuban idioms, habits and customs and are, consequently, to be preferred.

Practically all of the motion picture houses display advertising slides. The average theater is not open during the day, but has performances from 7 p. m. to midnight. Fees charged are from ten cents to twenty cents. There are no organizations in Havana through

When Advertising Abroad:

Remember that advertising is more highly developed in this country than elsewhere.

Study closely the people and the country you would reach.

Do not be imposed upon by mere translators.

Write your copy for and at the particular people you would reach.

Beware of local superstitions.

Study local prejudices as to pictures and colors.

Never translate an American advertisement; write local ones.

Advertising is not an international art, but always a national one.

UNVEILING THE SALMSON ENGINE MYSTERY

THE Salmson engine! You remember hearing much about it during the war. You heard, you well recall, that it was the only French engine that proved to be entirely satisfactory for airplane use. But you did not hear what you wanted to know about this engine. To most of us on this side it was a war mystery.

But the mystery is dispelled. W. F. Bradley, the European Correspondent of AUTOMOTIVE INDUSTRIES, *has lifted the veil. He has sent to us a comprehensive set of pictures of this engine and a technical description. He tells about the "water-cooled cylinders mounted around a single crankcase" and other outstanding features. Mr. Bradley was familiar with the performance of this engine before the war and he knows its history as well as its mechanical features. His article, with the pictures, will appear in an early issue.*

which advertising slides might be placed and it is necessary to make arrangements with each theater separately. The rates have not been standardized. Practically all of the motion picture houses in Havana are well patronized and screen advertising should be as effective as in the United States. There is an excellent opportunity for the use of motion picture films rather than slides.

Street car advertising in Havana cars is controlled by a New York firm. In addition to this card space in the cars, every street car in Havana carries advertisements in colored glass across the top of the windows, which can be read from the outside only.

Poster and painted-board advertising exists only in Havana, where its volume equals that of similar cities in the United States. This offers excellent opportunities for the use of pictorial copy. The colors should be the primary ones, the treatment simple and strong, and with the trademark reproduced in the same colors as the automobile.

Electric signs, hand bills, calendars and novelties can also be used to advantage. Because of the climate, the average store window is arranged for comfort rather than display purposes. The fronts of the stores are formed by rolling iron shutters. But often in these stores, cut-outs, signs and other advertising can be so placed that it attracts the passerby. Some of the newer class stores have plate glass windows.

In Cuba the rights of propriety in trademarks are derived entirely from the law and depend entirely on the registration of the mark and, once registered, its ownership is fixed for 13 years. The cost of registration is $12.50, with renewal at the same price. If a new trademark is selected for special use in the Latin-American countries, it is wise to select one that is easily pronounceable in all languages. Spanish has certain pecularities. It has no letter "W" and seldom uses the letter "K".

The greatest simplicity in trademark design is advised. and the design should be colored effectively. Mr. Sanger recommends registration of the trademark in every Latin-American country at the beginning of the export business. An International Bureau for trademark registration at Havana has been established. The payment of $50 obtains registration for the trademark in all of the countries represented in the Bureau.

Summarizing, Mr. Sanger declares Cuba is the logical "first point of attack" for any contemplated Latin-American advertising campaign. It is buying American goods in increasing quantities every year, is exporting most of its products to the United States. is a close geographical neighbor and is friendly to this country.

Small packages of engraving matrices or printed matter can be sent from the United States to Cuba without payment of duty. Copper electrotypes are dutiable at the rate of 20 cents per 2.2 lb. Duty is based on gross weight with a tare allowance of 13 per cent for cases and 5 per cent for other ordinary receptacles. Articles not especially mentioned, including type and electrotype of zinc or lead, are dutiable at 15 cents per 2.2 lb. Wooden electrotypes are dutiable at 25 per cent ad valorem. In each case the duty from the United States is one-fourth less than from all other countries.

Appendix attached to the bulletin includes a list of all of the publications, daily, weekly and monthly, in Cuba.

The following table shows the tariff numbers, the general rate of duty, and the rate for United States goods, on various articles of interest to advertisers:

Tariff No.	Articles	General rate	Rate on United States goods
		Per 100 kilos.	Per 100 kilos.
155	Books, bound or unbound, and similar printed matter (gross weight)	$1.625	$1.30
157	Pictures, lithographs, chromolithographs, oleographs, etc., printed from stone, zinc, aluminum, etc., used as labels, flaps, bands and wrappers for tobacco or other purposes:*		
		Per kilo.	Per kilo.
	a. 1 to 3 printings, including bronze (bronze printing counted as 3 printings) but not metal leafwork, other than maps and charts	$0.065	$0.0455
	b. 4 to 7 printings, inclusive, not including any metal leafwork, other than maps and charts	.26	.182
	c. 8 to 13 printings, inclusive (not metal leafwork), other than maps and charts	.52	.364
	d. More than 13 printings, including all metal leafwork, other than maps and charts	1.04	.728
		Per cent	Per cent
315	Chromolithographs for advertisements, provided the advertising renders them unfit for other purposes. ad valorem	32.5	26
345	Lithographs, posters, manufacturers' catalogs, calendars and folders for advertising purposes only, having no commercial value and intended for free public distribution	Free	Free

Articles classified under No. 345 are those only which have no commercial value, such as advertisements in the cheapest form, presented in small quantities. Those which come as an ordinary importation of merchandise or as part or the whole of an invoice and manifested consignment are dutiable under the appropriate tariff numbers. Articles excluded from No. 345 on account of having commercial value shall be classed under No. 315, unless dutiable as printed matter.

*Duty based on gross weight with tare allowance of 10 per cent for cases and 3 per cent for other receptacles.

Are You Considering

INDUSTRIAL REPRESENTATION?

IF you are, here is something well worth your reading? It is the fearless plan adopted by the Goodyear Tire & Rubber Co., with an introductory statement by Mr. Tipper, who has been making a study of this industrial development. No employer can afford to ignore this question to-day.

By Harry Tipper

FOR some time articles in these columns have noted progress in the adoption of plans calling for industrial representation in the factories in the automotive field and other fields. One of these plans which has several new points of significance is the plan adopted by the Goodyear Tire & Rubber Co. and was reported fully by them in the last issue of their publication.

It will be seen that this plan, for the first time in any industrial plan for joint consideration of working conditions, differentiates between executive powers and legislative powers as required in the industrial organization.

Those who have been following the articles which have been appearing in AUTOMOTIVE INDUSTRIES upon the subject of industrial organization, with particular reference to the human relations, will remember that one article, in the issue of Dec. 5, was devoted solely to the exposition of the two fundamental necessities in all human organizations—those required to govern the operating or executive functions of organization and those required to deal with the legislative necessities.

This fact has been recognized to some degree in political organization, but it has not received the attention it deserves in connection with industry, and it is vaguely understood by many manufacturers who confuse the machinery for legislative purposes with the machinery for executive or operating purposes. This is seen in the constant fear, before the average manufacturer, that legislative machinery will eventually assume operating control.

It will be noticed that the first two provisions of the Goodyear plan, which is given in detail here, differentiates carefully and clearly between the executive powers and the legislative powers. The wording of the first paragraph, in relation to executive powers, is thoroughly in accordance with the requirements of orderly industrial organization and carries into the plan the sense of the paragraph in the article printed in AUTOMOTIVE INDUSTRIES of Dec. 5, which states:

> "The operative functions require continuous decision, supervision and obedience to that supervision. They require the lodgment of large powers in the governor or leader and an equally large measure of acquiescence in those who are subject to the government."

It will be seen that the plan of the industrial representation is in all respects, as far as its operation is concerned, modeled upon the political plan which is contained in the Constitution of the United States.

It will be noted also that in Clause 9, the House and Senate by a two-thirds majority can pass a ruling or regulation for the factory over the veto of the factory manager. This is an interesting departure and is along the lines of the veto provision adopted by William Filene & Sons a number of years ago.

In paragraph 8 of the regulations is a provision allowing a bill to become a factory regulation within 30 days if the factory manager fails to sign it, so that no demand of the House and Senate can be permitted to die by inaction.

An additional feature of this plan, which is out of the ordinary, is indicated in paragraph 13 in the requirement of an oath of office. It has been found valuable in all government work and in all positions of public responsibility to require of the participants in that responsibility solemn agreement to the general provisions under which they are to work. The character of the oath in this case seems to be of the right kind and the demand upon the representatives and senators to agree to the provisions stated, by taking oath thereto, is only in accordance with public practice which has been justified by long experience.

YOU CANNOT AFFORD TO MISS THIS!

MANY questions are being asked regarding the program of the radicals of labor and the reasons for their apparent ease in turning unrest to their advantage.

These questions indicate that there is a great deal of interest in this particular development and next week Mr. Tipper's article will deal with the program of the radicals, their methods of working and the way in which they have used the prevailing unrest to further their purposes.

INDUSTRIAL REPRESENTATION PLAN

Proposed by the Council of Industrial Relations of the Factory of The Goodyear Tire & Rubber Co., Akron, Ohio

This Plan of Industrial Representation is unanimously approved by the Council of Industrial Relations, comprised of the following:

P. W. Litchfield	E. S. Rose	B. W. Waugh	D. R. Stevens
O. P. Kidder	E. Hartman	C. McClister	C. Slusser
H. D. Hoskin	F. B. Campbell	H. O. Allman	W. C. State
C. R. Johnson	F. H. Fuller	H. Grow	Wm. Stephens

THE Council of Industrial Relations, composed of representatives elected by Goodyear men and women, foremen elected by Goodyear foremen, and executives appointed by the Goodyear factory management, after having thoroughly considered the subject of industrial representation for securing justice to both men and management through co-operative methods has evolved the following plan for industrial co-operation at Goodyear, and presents this plan to Goodyearites in the sincere belief that its acceptance by management and men of the Goodyear factory will prove beneficial to all.

PLAN
For Akron Factory of The Goodyear Tire & Rubber Co.

1. Executive Powers.

All executive powers for operation of the Goodyear factory shall be vested in the management, and shall not be abridged in any way except in accordance with the legislative powers granted in this Industrial Representation Plan.

2. Legislative Powers.

All legislative powers granted in this Industrial Representation Plan shall be vested in an Industrial Assembly of the Goodyear factory which shall consist of two (2) houses, namely, a Senate and a House of Representatives.

3. The Industrial Assembly.

The Industrial Assembly shall be composed of forty (40) Representatives and twenty (20) Senators, elected by the Industrians of the Goodyear factory, who shall meet separately or jointly, on the first Monday in each month in Goodyear Hall. Representatives shall be elected for one year and Senators shall be elected for two years.

Each Representative and each Senator shall have one vote.

Each House shall vote independently of the other.

Each House shall determine rules for its proceedings and shall keep a record of its proceedings.

4. Unit of Representation—Precinct and District.

The Goodyear Factory shall be divided into forty (40) precincts. Precincts shall be determined so as to include substantially an equal number of people, and with due regard to departmental classification of the factory.

Each precinct shall have the right to elect one Representative.

The precincts shall be further arranged into groups of four, and each group shall be named a district, and each district shall have the right to elect two Senators.

5. Method of Election and Recall of Senators and Representatives.

Election of Senators and Representatives shall be held in the Goodyear Factory annually on the second Monday in October by secret ballot, and the Assembly shall be convened on the first Monday in November. At each annual election there shall be forty Representatives and ten Senators elected, except in the first election, when there shall be twenty Senators elected.

A Representative or Senator may be recalled on petition signed by two-thirds of the voters in his precinct or district, and approved by two-thirds of the House of which he is a member.

Upon severance of employment with the company, a Representative or Senator shall immediately and automatically cease to hold office.

6. Qualifications of Representatives and Senators.

No person shall be a Representative who shall not have attained the age of 21 years and who shall not be an Industrian of Goodyear, and not have had one year's continuous service record in the factory immediately prior to date of election.

No person shall be a Senator who shall not have attained to the age of 25 years, and who shall not be an Industrian of Goodyear, and not been in good standing on the pay roll of The Goodyear Tire & Rubber Company for five years, the last two of which shall have been a continuous service record immediately prior to election.

If vacancies in the seats of Representatives or Senators happen by resignation or otherwise, the one who shall have received the next highest number of votes from the precinct or district in which the vacancy shall have occurred shall fill the vacancy.

7. Qualifications of Voters and Definition of Industrian.

A Goodyear Industrian must be 18 years of age, must be an American citizen, understand the English language, and have a six months' continuous service record in the Goodyear Factory immediately prior to election. Each Goodyear Industrian is entitled to vote. [CONTINUED ON NEXT PAGE]

Industrial Representation Plan

[CONTINUED FROM PRECEDING PAGE]

8. Power and Procedure of The Industrial Assembly.

The Articles of Incorporation of The Goodyear Tire & Rubber Company and the laws of the State of Ohio fix the final authority and responsibility for management of the company in its Board of Directors. Therefore, subject only to the right of the Board of Directors to veto or annul, the power of the Industrial Assembly shall be as follows:

The Industrial Assembly shall have legislative power to make changes in Factory Rules and Regulations which from time to time have been or shall be made by the management as provided in Article 1, on the subject of wage adjustments, working conditions, and the adjustment of grievances in accordance with the following procedure:

Every bill which shall have passed the House of Representatives and the Senate, shall, before it becomes a Factory Rule or Regulation, be presented to the Goodyear Factory Manager. If he approves, he shall sign it, but if not he shall return it with his objections to the House in which it shall have originated, who shall enter the objections at large upon their record, and proceed to reconsider it. If after such reconsideration two-thirds of that House shall agree to pass the bill, it shall be sent, together with the objections, to the other House, by which it shall likewise be reconsidered, and if approved by two-thirds of that House it shall become a Factory Rule or Regulation. But in all such cases the votes of both Houses shall be determined by yeas and nays, and the names of the persons voting for and against the bill shall be entered on the record of each House respectively. If any bill shall not be returned by the Factory Manager within thirty days (Sundays excepted) after it shall have been presented to him, the same shall be a Factory Rule or Regulation in like manner as if he had signed it, unless the Assembly by failure to provide proper means to receive it shall prevent its return, in which case it shall not be a Factory Rule or Regulation.

9. Approval and Veto Powers of the Factory Manager.

Every order, resolution, or vote, to which the concurrence of the Senate and House of Representatives may be necessary (except on a question of adjournment) shall be presented to the Factory Manager of the Goodyear Company, and before the same shall take effect shall be approved by him, or being disapproved by him, shall be repassed by two-thirds of the Senate and House of Representatives according to the rules and limitations in the case of a bill.

10. Joint Conferences.

On matters of joint interest to men and management, such as wage adjustments, working conditions, and the adjustment of grievances, Joint Conferences may be called where representatives of the men meet an equal number of representatives of the management. Frequent conferences are desirable for the consideration of constructive suggestions of mutual interest.

11. Joint Conferences, How Formed.

The Industrial Assembly shall appoint six (6) Industrians, three from the Senate and three from the House of Representatives, and the Factory Management shall appoint six (6) Industrians to meet as a joint conference. Persons thus selected shall be duly accredited representatives of the Goodyear factory men and management for consideration of and co-operation upon subjects of mutual interest. The Industrial Assembly shall maintain standing committees composed of three members of each house to facilitate quick action in securing a joint conference.

12. Industrial Representation Plan — How Amended.

The Industrial Assembly whenever two-thirds of both Houses shall deem it necessary shall propose amendments to this Industrial Representation Plan, which shall be valid to all intents and purposes as a part of this plan when approved by the Factory Manager. In case amendments have been passed by a two-thirds vote of both Houses over the veto of the Factory Manager, such amendments must be approved by the Board of Directors of The Goodyear Tire & Rubber Company before becoming valid.

13. Oath of Office.

Before entering upon his duties, each Representative or Senator shall take and subscribe to the following oath, which shall be administered by any officer empowered to administer oaths under the laws of Ohio: "I solemnly swear (or affirm) that I will faithfully support the Constitution and laws of the United States and the State of Ohio and the Industrial Representation Plan of The Goodyear Factory, and that I will to the best of my ability faithfully and conscientiously discharge the duties incumbent on me as a Representative (or Senator) under such plan."

14. Guarantee Against Discrimination.

There shall be no discrimination against any Goodyearite on account of membership or non-membership in any labor organization, or against any Representative or Senator for action taken by him in performance of his duties as outlined in this Plan.

15. Industrial Representation Plan—How Ratified.

This Industrial Representation Plan shall become effective when a majority of the Industrians of the Goodyear Factory and the management of the Goodyear Factory shall have authorized the present Industrial Relations Council to place their signatures hereon.

How to Reach Congress

AMERICAN manufacturers are to-day aware of the needs of industry for constructive action by Congress to promote business along the new lines. Especially is this true of manufacturers who are entering the export field. The needs have been stated recently at conventions and are developing from day to day in business experience.

Never before has there been so great a need for clean-cut co-operation between industry and Congress. There are problems of railroad transport, marine transport, tariffs, commercial aeronautics, parcel post, and numerous other subjects, none of which can be solved by business without Congressional action and none of which Congress can properly handle without the advice of business.

But individual protests, criticisms or suggestions, sent singly and at spasmodic intervals, to the legislators at Washington are wasted energy. The Congressional Record prints daily petitions of this character, read into the Record by a Congressman, clipped and sent to the petitioner whose only satisfaction is reading his protest in print.

When the farmers set out to have the day-light law repealed, they did not employ such haphazard methods. They used concerted efforts. When labor wants legislation, members of unions do not write individual letters. Labor's demand is made through organization. And industry vitally in need of legislation—a legislation important to the entire public—must work concertedly with Congress to gain its end. Congress heeds popular demand. Popular demand is the employment of concerted effort.

Patent Office Needs

THE Patent Office Society has recently entered the lists of those seeking publicity. This society was organized by employees of the U. S. Patent Office with a view, according to the society statement, of improving the service of this office to those seeking patents and those using patents—or rather it might be put to the honest persons in these two classes. One of the important objects is to make possible more certain profit to the inventor and better protection for the legitimate buyer of a patent.

With these worthy objects in view, the society has published some exceedingly interesting pamphlets. One of these tells the history of the U. S. Patent Office and another tells of the legislation that the society members think is needed to carry out their objects.

The history of the patent office is an important document. It reviews briefly the patent history of the colonies, but the story really begins in 1790, when the first patent statute was written. Patents were placed under the care of the Secretaries of War and State and the Attorney General. Thomas Jefferson, as Secretary of State, was a member of that first board, and it is testified from the handwriting in the record books that Mr. Jefferson was a very active member.

By degrees the statutes were changed until the protection thrown around the inventor was fairly complete and then, the pamphlet says, the patent laws of this country began to attract attention of the world. The writer says that "all of the civilized nations of the world, save one, have modeled their patent laws after those of the United States."

There is an interesting bit of history in that part of this story which reviews the influence of inventions on the history of the country. The climax of this story is quoted from an Englishman, Sir Robert A. Haffield, himself a noted inventor, who tells of a conversation with a Japanese statesman. The Japanese told Sir Robert that when the leaders of that country set about making their country great, they looked up the history of the great companies and found that the United States had made the most rapid and substantial growth. They analyzed this development and concluded that it was due to "patents." So Japan modeled her patent laws after the United States.

This story, as told by the Society of the Patent Office, leads up to the great objective; that is—to get certain legislation passed by Congress. This proposed legislation is outlined as follows:

(1) The establishment of a single Court of Patent Appeals to take over the appellate jurisdiction now lodged in the nine independent Circuit Courts of Appeal.

(2) The establishment of the Patent Office as a separate institution independent of the Department of the Interior.

(3) An increase in the personnel of the Patent Office to enable it to render prompt and efficient service and an increase in the salaries to approximate those paid in outside patent work so that qualified examiners may be kept in the public service.

(4) A change in the law relating to damages in infringement suits to answer one of the most common and strongest reproaches against the patent system, namely, that a patent does not ordinarily pay the inventor any money.

Certainly no group has better reason to ask definite and well defined patent legislation and practices than the automotive industry. Patents are the vital factor in the present manufacture and in the advancement of the industry.

The object of this presentation of the subject is to interest the men of the industry in the U. S. Patent Office, so that they will investigate its needs and help to define a policy that will make for as great a scope of usefulness as is possible. We commend the publications of the Patent Office Society as a good place to begin this study.

Supply and Demand

THE material situation is rapidly getting back to a supply and demand basis. Since 1917 the market has more or less been controlled by the Government and even where this control has not been directly exerted, it has had a marked influence on the market. We are now practically free from any form of Government regulations and as a result the market is seeking its own level. Conditions more nearly approach an open and free market than they have since the war really got under way.

During the stage of readjustment to actual purchasing conditions, there are going to be sharp fluctuations, or, what amounts to the same thing, wide differences between purchase prices of material of a similar nature brought from different sources. This will soon readjust itself, however, and while prices can be expected to remain high, due to the placing of large orders, nevertheless the buyer has more of an opportunity to shop than he has had for four years. Taken as a whole, industry may be said to really welcome the return of the buyers' market. Conditions were extremely difficult during the period when the market was entirely on the sellers' side.

One important result is sure to be longer time buying, which ought to have a steadying influence on the market.

Cost of Tractor Plowing

THE complete cost of tractor operation involves a good many items, such as interest on investment, depreciation, etc., which it is difficult either to determine accurately for a given period or to apportion properly to the acre of ground plowed. However, two of the chief items of cost—at least if there is plenty of work for the tractor so that the pro rata fixed charges are low—are labor and fuel. In a recent demonstration at Delavan, Wis., these two items of cost were determined, and the results arrived at are interesting as throwing some light on the question of how the cost of plowing varies with the size of the machine used—that is, the number of plows pulled.

The great majority of the tractors demonstrated were three-bottom machines, and the figures of cost arrived at for this type may therefore be regarded as a good average of what may be expected. In the other classes the number of individual machines was smaller, and the average cost figures therefore do not bear quite so much weight. Each outfit was operated by one man. In estimating the results, labor was figured at 60 cents per hour, kerosene at 12.7 cents per gallon and gasoline at 23.7 cents per gallon.

One thing that tends to prevent a logical comparison of the different classes on the basis of cost per acre plowed is that some of the machines ran on gasoline, which costs about twice as much per gallon as kerosene. Both of the tractors in the single bottom class burned the more expensive fuel, as did one of the four tractors in the two-bottom class.

As might be expected, the cost of plowing decreases as the size of the machine used increases (if only the items of labor and fuel are considered), the average cost figures for the four sizes of machines demonstrated being as follows: Single-bottom, $2.67 per acre; two-bottom, $1.20 per acre; three-plow, $1.14 per acre; four-plow, $1.12 per acre. The very large difference in the plowing cost between single-bottom and two-bottom tractors and the comparatively slight difference between the cost with the other tractors are explained by the fact that both single-bottom tractors used gasoline for fuel, which practically doubled their fuel cost, while, on the other hand, most of the two-plow tractors plow at considerably higher speed than the rest, which tends to keep down the labor cost with them. These two factors, one forcing the single-bottom plowing cost up and the other the two-bottom plowing cost down, are together responsible for the wide gap between the two figures.

There is one rather peculiar item in the published data of the demonstration. These data are arranged in tabular form and the last column of the table gives the fuel and labor cost per acre per bottom. This means that the fuel and labor cost per acre, which is undoubtedly the factor that most interests the farmer, was divided by the number of bottoms used—for what reason it is hard to conjecture. The quotients thus obtained are certainly without any practical value.

Summer Meeting at Ottawa Beach Pleases Engineers

Entertainment Vies with Discussion in Attracting 800 S.A.E. Members and Families

Fuel Situation Given Prominent Attention, Dr. Pogue's Paper Leading Open Talk

OTTAWA BEACH, MICH., June 26—As a climax to the program of entertainment and recreation arranged to lighten the technical side of the summer meeting of the Society of Automotive Engineers, 800 members and their associates, with the wives and families of many, witnessed or took part to-day in the field sports. With the cares of the wartime period laid aside, the engineers entered heartily into the day's events and into the tournament that began on Monday and will continue until the final session to-morrow.

Division of the meeting into sections gave virtually unlimited opportunity for discussion of papers, at the same time adding to the hours of pleasure and sociability, of which the members and their companions took full advantage. The Lake Michigan resort, combining water and shore life and offering an endless variety of amusements, proved popular with the visitors, who patronized in large numbers the golf courses, tennis courts and ballrooms, also "seeing Michigan," in a limited degree at least, in tours over the automobile highways.

As a means of entertainment, along with practical demonstration, E. H. Colpitt, assistant chief engineer of the Western Electric Co., talked to the engineers and their guests on the wireless telephone, coincidentally putting the apparatus into operation between the auditorium and a motor boat a mile and a half off shore. A sound intensifier had been installed, and the audience heard the conversation between the lecturer and the boat crew, which was followed by an exchange of questions and answers between the boatmen and persons in Chicago, part of the way over a wire circuit.

Mr. Colpitt reviewed the development of the wireless telephone and discussed its future use, at the same time stating its limitations.

Under the sectional plan, the members found the technical papers grouped logically, with opportunity for informal discussions intended to assist the development of the various branches of the industry. There were spirited sessions on the passenger car and motor truck situations, with large attendances.

Keenest interest was shown in Dr. Joseph E. Pogue's fuel paper, and the discussion following it emphasized the necessity of concerted action to insure a continued supply and to make available advance information regarding impending changes in its character. It was felt that the action of the automotive and fuel industries in naming a committee jointly to study the problem would dismiss tendencies toward panic over the situation, and prove of assistance to engine and carbureter designers who must know in advance the fuel which their products must be made to utilize. The meeting room was crowded during the discussion.

The standards committee's meeting on Monday resulted in submission of a considerable number of proposed standards and recommended practices to the society.

Following the custom of previous meetings, section reports were printed and distributed to members in advance of the time set for their consideration, facilitating discussion and voting.

DAYTON-WRIGHT SOLD

WASHINGTON, June 24—Attempts made yesterday in Congress to prevent the purchase of the Dayton-Wright Airplane Factory, Dayton, Ohio, for $3,260,000, which was appropriated last week in the Army appropriation bill, were defeated. The sum appropriated will buy the factory and adjoining land, which includes 1586 acres. The factory and land will be used as an Air Service Engineering Experimental Station.

REO PLANS EXPANSION

LANSING, June 22—The Reo Motor Car Co. is breaking ground for a new machine shop, 200 x 514 ft., containing 132,518 sq. ft. of floor space. This is the first step of an expansion program which will revolutionize production and increase the pay-roll by 1500 men. The completion of this program will occur in the fall. A part of the building will be 3 stories high while the rest will be 2 stories. When this building is completed the motor building department will be moved to the former truck plant. It is the plan to build engines complete.

BETHLEHEM IN MERGER

NEW YORK, June 24—Formation of a company under the laws of Delaware, to purchase the stock of the Bethlehem Motors Corp., Allentown, Pa., and the North American Motors Co., Pottstown, Pa., is announced.

The new company, which will have an authorized capital of 130,000 shares of stock of no par value, is headed by Arthur T. Murray, with D. G. Dery, S. C. Potter and H. B. Hall, vice-presidents; treasurer, Martin E. Kern, and secretary, M. H. Deary. Allan A. Ryan, recently chosen head of the Stutz Motor Car Co. of America, is one of the directors.

A report of the new company after refinancing shows: Cash in banks and on hand of $1,494,188; notes receivable, $29,301; accounts receivable net, $293,227; notes payable, $868,757; accounts payable, $184,291; common stock, no par value, and surplus, $3,393,966, and total assets and liabilities of $4,466,039.

Plan to Build Up S. A. E. Membership

Society to Seek Out Unenrolled Among 20,000 Prospects—President's Address

OTTAWA BEACH, MICH., June 24—The question of future membership came up prominently in the business session of the S. A. E. summer meeting last night. By C. C. Hinkley's report for the membership committee it was shown that the roster on June 1 contained 4,045 names of all grades, a gain of 772 during the last year. It was stated that there were almost 20,000 eligibles in the country, and plans to recruit these prospective members were discussed.

The present membership includes 4,045 members of different grades, 99 offiliated members of different grades, 99 affiliated point was raised as to the advisability of limiting the section associates in proportion to the number of full members of each section. This question is a result of the rivalry of the Metropolitan and Detroit sections. There was a difference of opinion as to whether a section associateship should be limited to one year or two years.

The treasurer's report, read by Coker F. Clarkson, showed a balance of $128,281.99.

G. P. Dorris of St. Louis, C. C. Hinckley of Detroit, and W. H. Conant of Cleveland were made members-at-large of the nominating committee to serve with members from the sections in arranging at once for organization.

A summary of the standards committee report, as read by A. B. Bachman, was adopted, making all the material in the issue S. A. E. standard, subject to ballot of the membership.

David Beecroft reported for the meetings committee that the large number of reservations for the summer session, aggregating 750, had dictated choice of the Ottawa Beach meeting place, which he characterized as likely to prove satisfactory, despite some disadvantages. Charles M. Manly, president of the society, declared, in his annual address, that opportunities and obligations facing the automotive industry called for earnest devotion of talents and energies, particularly to solve problems connected with the resumption of peace.

Of the future of the industry, Mr. Manly said:

"In the subdivision of automotive engineering work having to do with motor trucks, the real work of the engineer has hardly as yet been begun. True it is that motor trucks are being sold and are daily hauling thousands of tons of merchandise and general freight, but the careful study and collection of data for accurately pre-determining the best operating equipment, organization and personnel to meet given conditions at a definitely predetermined cost has hardly been started. This single phase of automotive engineering presents more problems for the engineer

French Automotive Restrictions Lifted

Cars, Tires and Parts May Be Exported Freely — New Ad Valorem Surtax Applied

WASHINGTON, June 23—The restrictions against the importation of automobiles, tires and parts have been lifted by France and these commodities can now be exported from the United States to that country freely. This information was received officially by the Department of Commerce here to-day.

It is expected by Government officials here that Great Britain, as a result of France's action, will also remove restrictions in the near future and allow automobiles to be imported from the United States.

Information also received by the Department of Commerce provides for a new ad valorem surtax, based on c.i.f. or landed values at French customs houses. Twenty per cent ad valorem is the extreme limit of the surtax under the minimum and 40 per cent ad valorem under the general tariff. The amount of surtax to be applied to pamphlets could not be learned here, but it is anticipated that regardless of the tax, automobiles will be ordered in great quantities.

Although it is not known in Washington just what plans the Liquidation Office of the American Expeditionary Force has formulated for the disposition of the motor trucks and cars in France, it is understood here that the removal of the motor restrictions will allow the taking over of trucks and cars by the original manufacturers if they so desire, and if the War Department should consent to the resale of these trucks and cars to consumers in France upon payment of the French duties. It is also possible, under the new regulations, that the War Department may sell trucks and cars to consumers in France upon payment of French duties. What disposal will take place has not been determined.

France has decreed that all trucks and cars sold to consumers for use in France by the American Expeditionary Forces will entail the payment of the French duties, but if these cars and trucks are sold in France for use outside of French territory, there is no necessity for payment of French duties.

—

Another View

PARIS, FRANCE (*Special Cable*), June 20—From date automobiles weighing a minimum of 5511 lb. can be imported into France on pre-war duties, plus an ad valorem tax of 20 per cent maximum and 10 per cent minimum. The rate on tractors is 40 per cent maximum and 20 per cent minimum.

Automobile parts are now admitted on a pre-war basis plus an ad valorem tax varying from 20 to 30 per cent per ton to 15 per cent minimum, according to the nature of the article. The decree covering these changes does not especially mention touring cars, and while the situation as governing these is obscure, it is believed that they are still subject to 70 per cent duty.

Pre-war French duties on all automobiles were 70 francs general and 50 francs minimum per hundred kilos.

—

The foregoing is a reproduction of a cablegram received from W. F. Bradley, special representative of AUTOMOTIVE INDUSTRIES in France. It seems to indicate that the new ruling applies to trucks, as the minimum weight limit of 5511 lb. obviously is too great to affect the majority of passenger cars. As a kilogram equals 2.2046 lb. it is apparent that the new French ruling applies to vehicles in excess of 2500 kilos.

The restrictions mentioned in the Bradley cable are not noted in the cables received by the Department of Commerce at Washington from the commercial official attache at Paris. These official cables make no mention of weight restrictions but, as told in a dispatch from Washington on this page, indicate that all restrictions except duty have been removed. The Department of Commerce, when informed of the cable from Bradley, undertook to verify it, but at time of publication a reply had not been received from Paris.

PROPOSED SAXON PURCHASE

DETROIT, June 25—At the meeting of Saxon creditors called for to-day, a proposed purchase plan of the Saxon Motor Car Corp. will be outlined, according to information gained from an official of the company. No details are available for publication at this time. Should the deal go through, it is understood that Saxon financial interests would be in a strong position, and all creditors will receive payment in full.

MASSACHUSETTS AMENDS BILL

BOSTON, June 23—The Massachusetts truck and trailer bill, which caused so much protest because of its prohibitive fees, was amended June 12, passed in the House and is now in the Senate. The bill, as amended, materially reduces fees for the larger size trucks, but they still remain nearly three times the present fees. Fees for capacities over 7 tons probably relate to trailers as the law in this state prohibits gross weight in excess of 28,000 lb. This schedule, as applied to trailers, is still prohibitive.

The amended schedule follows:

Before Amendment, Capacity		After Amendment, Capacity	
1 ton or less	$10	1 ton or less	$10
Over 1 ton to 1¼ tons	15	Over 1 ton to 2 tons	20
Over 1¼ to 2 tons	20	Over 2 to 3 tons	30
Over 2 to 2½ tons	25	Over 3 to 4 tons	40
Over 2½ to 3 tons	30	Over 4 to 5 tons	50
Over 3 to 3½ tons	40	Over 5 to 6 tons	60
Over 3½ to 4 tons	50	Over 6 to 7 tons	70
Over 4 to 4½ tons	75	Over 7 to 8 tons	80
Over 4½ to 5 tons	100	Over 8 to 9 tons	90
Every additional ½ ton	50	Any capacity over 9 tons	100

Rules for French Show Next October

Regulations Received by N.A.C.C. Place American Exhibitors at Disadvantage

NEW YORK, June 25—The National Automobile Chamber of Commerce has received application blanks and regulations governing the International Automobile Show to be held at the Champs Elysées October 9 to 19.

Applicants are required to agree not to enter any other show in France before 1921, a prohibition which would stand against American exhibitors participating in an American exposition in France. To be rated on a par with the French, foreign exhibitors must have shown at three previous French exhibitions and be from countries imposing no greater than 15 per cent import duty prior to 1914.

On the latter provision, the N. A. C. C. says: "This places American exhibitors at a disadvantage, for the inference is that some provision will be made for them only after the others are cared for."

There will be 12 classes of exhibitors: Automobiles and chassis complete, motor trucks and buses, engines, etc., bodies and their parts, automobile dealers (established at least six months), bicycles and motorcycles, tires and tubes, accessories and parts makers, accessories parts dealers, forges and furnaces, sporting goods, automobile schools.

Plan to Build Up S. A. E. Membership

(*Continued from page* 1460)

to solve than if all of our records and data were suddenly swept away in railroad transportation engineering and it became necessary to immediately reestablish such data for the determination of proper freight rates.

"Similarly, in that newest of the branches of automotive engineering, which is destined to grow to be one of the biggest of the brothers in the family of giants spring from the union, under the magic influence of the electric spark, of atmospheric air and petroleum in the internal combustion engine, the commercial operation of aircraft, the scope and importance of the problems that must be given immediate and careful attention and study by the engineer are so great that I venture the prediction that within the next ten years there will be a larger number of engineers engaged exclusively on them than there are to-day in the total membership of this society."

FACTORY ADDITIONS

PORT HURON, MICH., June 21—Work on the first new unit of the Holmes Foundry Co. is well under way and will be completed by July 1. A new foundry plant is nearing completion at the United Brass & Aluminum Co. This plant is also building a large storehouse.

Goodyear Industrial Plan Put in Effect

Organization Follows Lines of National Legislature—Will Regulate Factory Conditions

AKRON, OHIO, June 24—Voice in the management of the Goodyear Tire & Rubber Co. has been given its employees by a new industrial representation plan. At a special election Monday, 92 per cent of the workers voted for it. The plan as outlined by the Council of Industrial Relations at the factory follows the lines of the national and state legislatures.

Executive powers are vested in the management, and legislative powers in the Industrial Assembly consisting of a House and Senate. The House is composed of 40 members and the Senate of 20, all elected by the workers. Members of the assembly are elected for 1 year, and members of the senate for 2 years.

An assemblyman must be not less than 21, and in the continuous employ of the company for not less than 1 year. A senator must be not less than 25, and in the continuous employ of the company for not less than 5 years. They may meet separately or jointly on the first Monday each month. Each representative and each senator has one vote.

A representative or senator may be recalled on petition signed by two-thirds of the voters in his precinct or district, and approved by two-thirds vote of the house of which he is a member. Upon his severance of employment with the company, a representative or senator automatically ceases to hold office.

Voters must be not less than 18, and in the continuous employ of the company for not less than 6 months.

The final authority for the management of the company, it is stated, is fixed by the laws of Ohio, in the board of directors. But subject only to the right of the directors to veto and annul, the industrial assembly shall have the power to make changes in factory regulations on the subject of wage adjustments, working conditions and grievances.

Provision is also made to consider such questions by joint conferences where the men meet an equal number of representatives of the management.

Legislative power of the assembly is exercised by the adoption of resolutions and measures which are signed or vetoed by the factory manager. When vetoed by the factory manager the bills may be passed by a two-thirds vote in each house, when they become a part of the factory rules and regulations. It is planned that there shall be no discrimination against any one whether a member in a labor organization or not, or against any member because of any vote he may cast.

WESTERN GOODYEAR PLANT

AKRON, OHIO, June 24—It is said here that the Goodyear Tire & Rubber Co. has secured options on 480 acres of land in Los Angeles, Cal., and will build a branch plant there. A capitalization of $7,500,000 is contemplated and has already been underwritten by a banking syndicate.

F. A. Seiberling, president of the company, stated that an option has been taken on Pacific coast land, but no definite decision has been made on the erection of a plant.

If the move materializes it will be the first expansion of any of the Akron rubber companies outside of this city. Los Angeles is on the route to the Goodyear rubber plantations in the Far East, and not far from the company's cotton plantations in Arizona.

WRIGHT-MARTIN MERGER

NEW YORK, June 26—Stockholders of the Wright-Martin Aircraft Corp. and the International Motor Truck Corp. will vote shortly on the proposed merger of the two companies, for which the following detailed plan has been worked out: Wright-Martin preferred will receive International first preferred, par for par, and accumulative, dividends to date not earlier than Sept. 1, 1919, nor later than date of issuance of new stock; Wright-Martin common stock will receive 2.8 shares of International second preferred and two shares of common of no par value for each 100 shares of Wright-Martin; Wright-Martin common will be reduced so that for each 100 shares now outstanding 25 shares will remain in hands of holders in addition to International stock received in exchange.

WADSWORTH PRODUCING AGAIN

DETROIT, June 24—The Wadsworth Mfg. Co., whose production has been greatly curtailed by a strike for several weeks, had practically a full force of new workers on the job. This fact so aroused the strikers that nearly 1000 stormed the plant, smashed 100 windows and badly beat a score of employees. Police reserves scattered the mob and made several arrests. The police have placed heavy guards at the plant and there has been no more rioting. This is the second riot at this plant.

PUBLIC AVIATION FIELD

DETROIT, June 24—Morrow Aviation Field, which cost the government $500,000, was opened to the public Saturday. This field was turned over by the War Department to the Universal Aviation Co., of which Henry M. Leland of the Lincoln Motor Co. is president. During the day several flights were made. The aviation company has four planes on the field. Six more are expected soon. The field's nine hangars will hold about 60 airplanes.

Regular passenger service between Detroit and Cleveland will start at once. Private owners of airplanes are making arrangements to keep their machines in Morrow field hangars. The field will be a landing and general service station for all visiting aviators.

Willys-Overland in Full Production

Normal Output Expected in 30 Days — Operating on 48-Hour Week

DETROIT, June 24—The Toledo, Elmira and Elyria plants of the Willys-Overland Co. are in full operation. Protected by the United States Government, the company believes that the crisis in their 2 months' labor difficulty has been passed. Approximately 5000 men are back in the Toledo plant, and fully 75 per cent of employees have returned in Elmira and Elyria. All departments are now in operation and production is being gradually increased.

Monday saw the first completed cars leave the Toledo plant's assembly line since the calling of the strike. While production is small at present, it will be back to normal within 30 days if present conditions continue. The company has invited all old employees to return with the exception of the radical leaders. The plants are operating on an 8-hr. 36-min.-a-day basis, and one half day Saturday, making a labor period of 48 hr. per week. The day the strike was called there were 13,000 men in the Toledo plant.

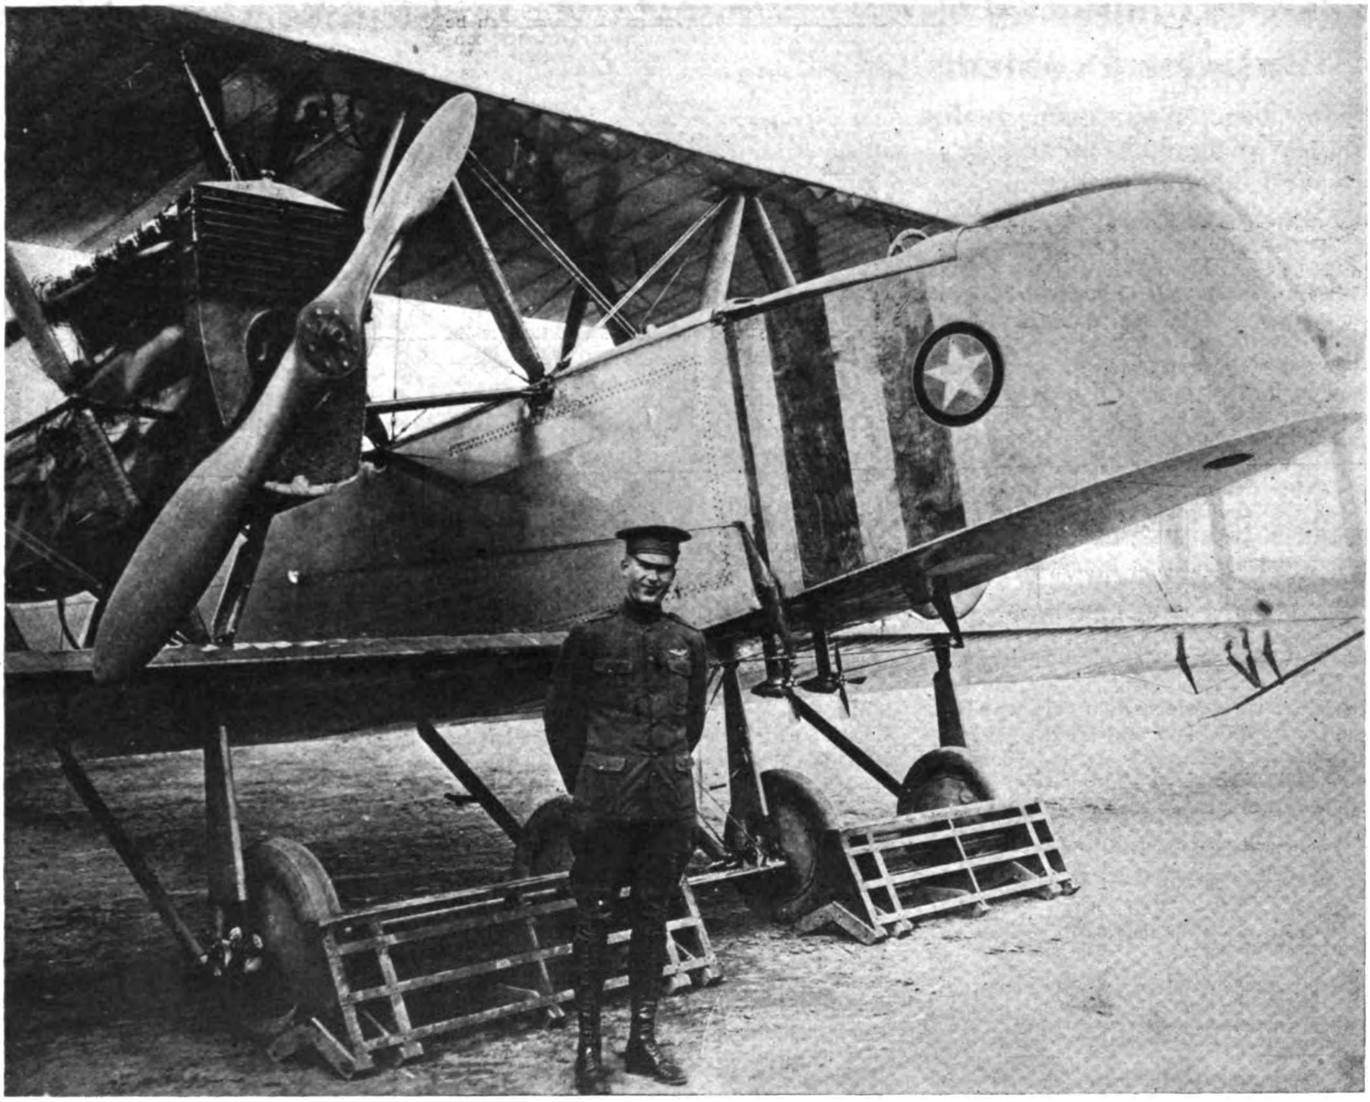
The injunction issued by Judge John M. Killets of the United States District Court, which ordered the Willys-Overland Co. to resume operations at once and continue the plant in operation for a period of 10 days, has been made permanent. This injunction also limits picketing and provides the deputizing of a large number of United States marshals to enforce the order. The action was brought in the United States Court by the Dail-Overland Co., distributer in a Southern state. This company named the Willys-Overland Co., the Toledo Lodge 105 International Association of Machinists, Automobile District Council, and 50 labor leaders as defendants in the action. This injunction will be lifted at the discretion of the court.

For 2 or 3 days following the enforcement of the first temporary injunction there was more or less trouble with strikers, but nothing serious. Several arrests were made.

S. F. BOWSER CO., LTD.

TORONTO, ONT., June 23—S. F. Bowser Co., Ltd., manufacturer, has been organized in Canada as a separate concern under the United States company. It has for a number of years been manufacturing and selling Bowser gasoline and oil pumps, tanks and storage systems under the control of the parent company at Fort Wayne, Ind.

H. C. Christie, who has been for a number of years connected with the Canadian factory of the Bowser company, recently as sales manager, has been elected manager, and R. E. Cummings, factory manager. Other officers are: President, S. F. Bowser; vice-president, S. B. Bechtel, secretary, H. J. Grosvenor; treasurer, W. G. Zahrt.



Capt. Roy N. Francis and the Martin Bomber in which he expects to make a one-stop flight from the Mineola field to San Francisco under the direction of the War Department. The plane carries U. S. Martin twin motors

Labor Approves of Scientific Research

Federation of Federal Employees Passes Resolution to Aid and Support Federal Research

ATLANTIC CITY, June 25—The newest section of the American Federation of Labor, the Federation of Federal Employees, has made its presence felt in the larger body by bringing about the adoption of the following resolution in the convention here:

"Whereas, scientific research and the technical application of results of research form a fundamental basis upon which the development of our industries, manufacturing, agriculture, mining, and others must rest; and

"Whereas, the productivity of industry is greatly increased by the technical application of the results of scientific research in physics, chemistry, biology and geology, in engineering and agriculture, and in the related sciences; and the health and well-being not only of the workers but of the whole population as well, are dependent upon advances in medicine and sanitation; so that the value of scientific advancement to the welfare of the nation is many times greater than the cost of the necessary research; and

"Whereas, the increased productivity of industry resulting from scientific research is a most potent factor in the ever-increasing struggle of the workers to raise their standards of living, and the importance of this factor must steadily increase, since there is a limit beyond which the average standard of living of the whole population cannot progress by the usual methods of readjustment, which limit can only be raised by research and the utilization of the results of research in industry; and

"Whereas, there are numerous important and pressing problems of administration and regulation now faced by federal, state, and local governments, the wise solution of which depends upon scientific and technical research; and

"Whereas, the war has brought home to all the nations engaged in it the overwhelming importance of science and technology to national welfare, whether in war or in peace, and not only is private initiative attempting to organize far-reaching research in these fields on a national scale, but in several countries governmental participation and support of such undertakings are already active; therefore be it

"Resolved, by the American Federation of Labor in convention assembled, that a broad program of scientific and technical research is of major importance to the national welfare and should be fostered in every way by the Federal Government, and that the activities of the Government itself in such research should be adequately and generously supported in order that the work may be greatly strengthened and extended; and the Secretary of the Federation is instructed to transmit copies of this resolution to the President of the United States, to the President pro tempore of the Senate, and to the Speaker of the House of Representatives."

This resolution is of peculiar interest to manufacturers whose business is confronted with the needs of research and who have been, during recent months, depending largely upon government bureaus to aid with this work. The Federation of Federal Employees includes in its membership many scientists and others who have been considered far separated from the average members of the Federation of Labor. But these men believe that their work is common with those who would improve labor conditions and they have enlisted. In the passage of their resolution, they were assisted by the teachers' organization.

P. G. Agnew of the Federal Federation, who was one of those who appeared before the resolutions committee, says that the sponsors of the resolution were closely questioned by the practical workers on that committee and that the practical miners, metal workers and other skilled trades questioned them sharply as to the nature of the work done by the bureaus.

WELLS ADDS TO MACHINE SHOPS

KENOSHA, WIS., June 20—The Frank L. Wells Co. is adding to its plant at a cost of about $50,000 fully equipped.

Allies to Confer on Business Problems

U. S. Chamber of Commerce Invites England, France, Italy and Belgium to Meeting

WASHINGTON, June 21—Invitations have been sent by the Chamber of Commerce of the United States to the United Kingdom, France, Belgium and Italy to send joint commercial missions to the United States in the fall as guests of the Chamber. The missions will arrive some time in October and will include representatives of the four governments. Full details are yet to be received from representatives of the Chamber abroad, who are arranging for the trip. The Executive Committee of the Chamber appointed a committee to-day to arrange entertainment for the missions and for conferences between members of the missions and American business men.

A canvass to-day by the Executive Committee of the Chamber shows that 12 of the 13 principles of industrial relations, sent to a referendum vote April 16, was carried. The thirteenth, recommending a system of national employment offices, received a majority vote, but not the two-thirds necessary to carry.

The principles submitted to vote are as follows:

1. Industrial enterprise, as a source of livelihood for both employer and employee, should be so conducted that due consideration is given to the situation of all persons dependent upon it.

2. The public interest requires adjustment of industrial relations by peaceful methods.

3. Regularity and continuity of employment should be sought to the fullest extent and constitute a responsibility resting alike upon employers, wage earners and the public.

4. The right of workers to organize is as clearly recognized as that of any other element or part of the community.

5. Industrial harmony and prosperity will be most effectually promoted by adequate representation of the parties in interest. Existing forms of representation should be carefully studied and availed of in so far as they may be found to have merit and are adaptable to the peculiar conditions in the various industries.

6. Whenever agreements are made with respect to industrial relations they should be faithfully observed.

7. Such agreement should contain provision for prompt and final interpretation in the event of controversy regarding meaning or application.

8. Wages should be adjusted with due regard to the purchasing power of the wage and to the right of every man to an opportunity to earn a living at fair wages, to reasonable hours of work and working conditions, to a decent home, and to the enjoyment of proper social conditions.

9. Fixing of a basic day as a device for increasing compensation is a subterfuge that should be condemned.

10. Efficient production in conjunction with adequate wages is essential to successful industry. Arbitrary restriction on output below reasonable standards is harmful to the interests of wage earners, employers and the public and should not be permitted. Industry, efficiency and initiative, wherever found, should be encouraged and adequately rewarded, while indolence and indifference should be condemned.

11. Consideration of reduction in wages should not be reached until possibility of reduction of costs in all other directions has been exhausted.

12. Administration of employment and management of labor should be recognized as a distinct and important function of management and accorded its proper responsibility in administrative organization.

13. A system of national employment offices, with due provision for co-operation with existing state and municipal systems, can be made, under efficient management and if conducted with due regard to the equal interests of employers and employees in its proper administration, a most helpful agency, but only if all appointments are made strictly subject to the Civil Service law and rules. Policies governing the conduct of a national system of employment offices should be determined in conjunction with advisory boards—national, state and local—equally representative of employers and employees.

Reorganization of the Chamber into departments to conform with the industrial, economic and social divisions of its membership is proceeding and will be completed this year. The best men obtainable for the places will be secured as heads of the departments.

The Chamber's board of directors will hold its meeting in Seattle in July. Members of the board living in the East will travel to Seattle together from Chicago, stopping at Denver, Salt Lake City and California cities for conferences with business interests. The return trip will be made by way of Minneapolis.

INDUSTRIAL CONFERENCE

WASHINGTON, June 20—A national conference for the consideration of industrial problems and the adjustment of differences between capital and labor is proposed in a joint resolution offered in the House by Representative Kelly of Pennsylvania.

It provides that the President be authorized to call a national conference to be composed of the following persons representing both employers and employees: E. H. Gary, William H. Johnston, Frank P. Walsh, Charles E. Hughes, A. B. Garretson, William K. Vanderbilt, Franklin K. Lane, William B. Wilson, John D. Rockefeller, Samuel Gompers. Daniel Guggenheim, Charles H. Moyer, J. P. Morgan, Andrew Furuseth, F. S. Peabody, Frank J. Hayes, J. Ogden Armour, J. Fitzpatrick, E. L. Stotesbury, W. D. Mahon and such other persons as the President may name, equally divided among leading representatives of labor and capital.

It shall be the duty of the conference to consider, with a view of the permanent solution of the same, such problems as may be presented to it relating to permanent relations of capital, labor, industrial management, adjustment of wages, settlement of industrial disputes, promoting improved conditions and greater industrial efficiency as a nation.

AMERICAN STEEL UNRESTRICTED

LONDON, June 10—Though American steel is selling in Great Britain at approximately $22 a ton less than the British product, the government is not prepared to restrict importations, Sir Auckland Geddes, president of the Board of Trade, stated in response to a question in the House of Commons.

The American Chamber of Commerce here reports that Sir Auckland declared an adequate supply of iron and steel was essential to the manufacture of articles for the British export trade, even if it had to come from the United States.

U. S. War Vehicles for Disposal by France

American Equipment Comprises 100,000 Vehicles—Manufacturers Will Maintain Stocks

PARIS, May 24—All automotive material held by the American army in France will be disposed of by the French Government. This material comprises 100,000 vehicles, of which 65,000 are trucks and touring cars, and about 35,000 motorcycles with or without side cars. Although it was decided that the American army should sell nothing direct, the French do not state when they will put this American material on the market.

It is understood that the intention of the French Government is to dispose of the whole of its own automotive material before allowing any American machines to be sold. Until now not a single American automobile has been sold in France, although a certain number have been disposed of for shipment to other European countries.

Telegrams have been received by the Motor Transport Corps in France from practically all American manufacturers who supplied cars or trucks to the army stating that they are prepared to maintain stocks and spare parts in France for the benefit of purchasers of their vehicles.

The first sales of American vehicles having any connection with the Motor Transport Corps took place at Verneuil this week. These vehicles comprise 68,000 rolling kitchens, water wagons, and other horse-drawn vehicles or trailers belonging to the Quartermaster Corps.

This is not Motor Transport Corps material and its presence at the Motor Transport Corps reconstruction park is explained by the fact that Verneuil undertook to repair not only motor vehicles, but also most of the Quartermaster Corps' rolling stock.

EXPORTS DECREASE IN MAY

WASHINGTON, June 20—Exports for May totaled $606,000,000, a falling off of $108,000,000 from the record set in April, but an increase of $55,000,000 over May, 1918, according to a statement issued by the Bureau of Foreign and Domestic Commerce, Department of Commerce. For the 11 months ended May, the export trade amounted to $6,308,000,000, an increase of $872,000,000 over the corresponding period of the previous year.

May imports were the largest in the history of that country's foreign trade—$329,000,000, a gain of $56,000,000 over April, and of $6,000,000 over May, 1918, which was the previous high mark. Imports for the 11 months ended May were valued at $2,803,000,000, an increase of $118,000,000 over a similar period in 1918.

The excess of exports over imports during the 11 months was $3,505,000,000, as compared with $2,751,000,000 for the corresponding period in 1918, and $3,364,000,000 in 1917, the previous record.

Tractors in 6 Classes for English Trials

Royal Agricultural Society Makes Public Comprehensive Regulations for 1920 Events

LONDON, June 10—The Royal Agricultural Society has made public the regulations drawn by that body for the Agricultural Tractor and Plow Trials to be held under its auspices in the autumn of 1920.

These regulations are especially interesting when compared with the regulations announced to govern the tractor trials to be held at Lincoln, England, in September of this year. These regulations, which were printed in the June 5 issue of AUTOMOTIVE INDUSTRIES, on page 1243, were drawn by the Society of Motor Manufacturers' and Traders', Ltd., which is the great national automotive organization of Great Britain.

The Royal Society regulations are more comprehensive in several particulars. They require demonstrations of hauling and of driving barn machinery. The price of the machine is also to be made a consideration in the awards. The exhibitor must set out very clearly the amount of fuel, the number of assistants and any other equipment he will require.

There are six classes with prizes of $100 and of $50 in each. The classes are as follows:

Class 1—Internal combustion direct tractor engine not exceeding 30 B.hp., suitable for plowing 2 or 3 furrows, 10 in. by 6 in. deep.

Class 2—Internal combustion direct traction engine over 30 B.hp., suitable for plowing 4 furrows, 10 in. wide by 8 in. deep.

Class 3—Direct traction steam engine plant, suitable for plowing 4 furrows, 10 in. wide by 8 in. deep. Engines to comply with the requirements of the Light Road Locomotive Acts.

Class 4—Internal combustion double engine set, with wire rope haulage, for plowing 3 or 4 furrows, 10 in. wide by 8 in. deep. Engines to comply with the requirements of the Light Road Locomotive Acts.

Class 5—Double steam engine set, with wire rope, haulage, for plowing 3 or 4 furrows, 10 in. wide by 8 in. deep. Engines to comply with the requirements of the Light Road Locomotive Acts.

Class 6—Self-propelled plow for plowing not more than 4 furrows, and not more than 10 in. wide by not more than 8 in. deep.

CLASSES I–V

1. For the purpose of these trials, an "agricultural tractor" shall be capable of:
   (a) Hauling direct in work or on the road, a plough, cultivator, harvester, or other agricultural implement.
   (b) Driving barn machinery.

2. The machines shall be tested for efficiency in carrying out the various classes of work.

3. Competitors will have to plow a given area of land with their own tractor and plow, commencing with the size of furrows specified for each class, during which the fuel and water consumption will be recorded, and subsequently varying the depth and width at the discretion of the judges.

4. Further trials on various classes of land with multiple plows and with other cultivating implements to be provided by the competitors, or which the society may have at its disposal and with which they may wish their tractors to be tried, may be made at the discretion of the judges.

5. Special attention will be paid, in the plowing and cultivating trials, to the compression of the land by the machine, the space and time occupied in turning, the uniformity of the furrow ends and evenness of the furrow.

6. The engines in classes 2, 3, 4 and 5 shall be capable of road haulage and will be tested in that respect over courses which will be set out over the roads and land selected by the society, and each competitor shall declare before starting what weight he is prepared to haul over such course; the fuel, water and other supplies consumed will be noted on the road trial. With selected motors hill-climbing trials may be made. Motors fitted with winding gear may have the opportunity of demonstrating its advantages. Motors must conform to the requirements of Acts of Parliament.

7. Each motor will be tested driving on to a pulley on a countershaft fitted with a brake. The diameter of the pulley, speed of countershaft, and load on brake assimilating to those of a threshing machine.

8. The time taken and attendance given will be noted in all trials.

9. Implements, except plows, unless otherwise stated, will be provided by the society.

10. The fuel, whether solid or liquid, will be provided by the society. The coal will be Welsh steam coal of uniform quality, and the petroleum or other liquid of one of the recognized brands.

11. Each competitor to state how many men will be required to attend to the machine.

12. The following are some of the points to which special attention will be directed:
   (a) Weight of machine.
   (b) Weight per inch width of wheel and diameter of wheel.
   (c) Mechanical design and construction.
   (d) Adaptability to various kinds of work, such as harvesting and the like.
   (e) Time taken to prepare for work.
   (f) Ease and safety of handling.
   (g) Ease of turning and space required for same.
   (h) Efficiency of winding gear.
   (i) Facility of attachment.
   (j) Wheel devices.
   (k) Attendance necessary.
   (l) Consumption of fuel, water and other supplies per unit of work done.
   (m) Price.

SELF-PROPELLED PLOWS—CLASS VI

The trials of these will be on the same lines as the plowing trials in Classes I and II.

13. The judges' decision, when duly recorded, will in all cases be final.

14. The society's Implement Regulations will apply to these trials generally.

FIELD FOR TRACTOR DITCHERS

LONDON, June 10—Demonstrations near Glasgow of a Buckeye tractor ditcher have revealed the comparative absence of plants of this sort in Great Britain. This affords an opportunity for American enterprise to benefit by an apparent need of machinery for ditch clearing and field drainage.

The new appliance, brought out with funds of the Board of Agriculture for Scotland, is the first of its kind in the British Isles and is intended to overcome the prohibitive cost of drainage by manual labor and the impossibility of obtaining enough labor.

The demonstration, arranged by the Highland and Agricultural Society, covered a period of ten days. The ditcher consists of a revolving wheel suspended to the rear of the tractor. On this wheel are the cutters or buckets, after the style of a dredger, and with the revolution of the wheel the earth is carried to the surface, where it is deposited on an endless canvas which takes it from the machine and places it about 2 ft. from the edge of the drain. One man and a helper operate the machine. On the first day of the demonstration it cut a field drain 200 yd. long, by 2 ft. deep and 12 in. wide, in 35 minutes. The ditcher can cut varying depths and widths. The consumption of gasoline works out as something like 0.9 gal. per hp. for a working day of ten hours.

British Tractor Scheme Expensive

Heavy Loss Sustained by Food Bureau in Ploughing Farmers' Lands

LONDON, June 3—Net losses of $4,199,850 were sustained by the Food Production Department in connection with its motor tractor ploughing scheme in 1917-18. It was expected when the project was organized that the entire cost would be recovered from the farmers.

Working expenses, depreciation of machinery, administration and other charges amounted to $5,812,210, while the total recovered or due for service performed was only $1,662,360.

The department obtained 6000 motor tractors through the Ministry of Munitions at $750 each, in addition to the cost of freight from America and assembling in this country. There was delay in delivery, and 2500 machines were re-sold to the contractors at $1000 each, and were subsequently re-sold by them to farmers at $1250 each.

In reply to the Auditor General's request for information as to why it was decided to re-sell to the contractors instead of direct to the farmers, it was stated that the department had no organization for obtaining orders from farmers, whereas the contractors already possessed such an organization.

As the bulk of the tractors were Fordsons, it is obvious that the Ford interests were indicated, and it is a fact that the bulk of the organization of the national tillage scheme was in the hands of Ford agents, a preference which was resented by the implement dealers at large.

It was in connection with this scheme that the organizing services of Sir Percival Perry were used.

The Fordson tractor is now listed at $1400. Reports of the machine is on the whole favorable.

In connection with its general work the Food Production Department placed 6000 tractors at the disposal of the farmers, trained drivers and plowmen and cultivated private land at less than cost.

TRACTOR ON PIKE'S PEAK

DENVER, COL., June 21—A tractor has scaled Pike's Peak. Following the demonstration here a Holt 5-ton caterpillar tractor, such as was used by the A. E. F., was sent to Colorado Springs and from there ascended Pike's Peak. In the last two miles 15-ft. snow drifts were overcome. Col. M. A. Champlin, recently of the A. E. F., was in charge of the tractor.

CHAMPION PLUG IN CANADA

DETROIT, June 23—The Champion Spark Plug Co., Toledo, has started work on its $225,000 Canadian branch in Windsor, Ont.

Automotive Steel Purchases Heavy

Change in Price Not Likely—Contracts on Sliding Scale Basis

DETROIT, June 19—More and larger orders for steel have been placed during the last 2 weeks than for any like period since the signing of the armistice.

The General Motors Corp. has just contracted for 200,000 tons. The Ford interests, including the Ford Motor Co., Henry Ford & Son, and the Ford Shipbuilding Co., have bought and most of the big automotive concerns in the Detroit district are protecting their source of supply by contract. The industry is apparently convinced that the price of steel is about stationary.

Few of the companies are binding themselves with "iron-clad" contracts. They are contracting to use a specified amount of steel during a period varying from 1 to 1½ years. All contracts are of the sliding-scale variety, based upon the market price of steel at the time of delivery.

None of the companies are agreeing to use a certain amount of steel each month, although some are furnishing estimates as to their approximate monthly consumption. They will not commit themselves to any agreement, however, which might force them to accept a fixed amount of steel each month.

While the big concerns are buying by contract the smaller companies continue to buy as they need material. This hand-to-mouth policy has been followed in a majority of cases ever since the signing of the armistice.

Not Waiting for Price Reductions

Automobile companies are buying heavily. The truck industry is beginning to place larger steel orders. The same also applies to the machinery men and parts makers.

Placing of steel orders by the railroad administration under protest is the big factor in steadying the steel market. While the administration was holding out for a lower price, the industry awaited expectantly and was prepared to take advantage of any price reduction. The purchasing agents were farily confident that the railroad administration would succeed in bringing prevailing prices down several points and no large orders were placed. It appears that the railroad administration has given up the fight and is preparing to buy at present prices. This action caused the industry to discard its watchful-waiting tactics.

As compared with 1914 prices, the cost of steel to-day is high, although 40 per cent less than it was 7 months ago. Blue annealed steel is priced at $3.55 per 100 lb. Plate steel at $2.65, and hot rolled steel, $3.05. The price on Nov. 19, 1918, for blue annealed steel was $4.25, which is 70 cents higher than the price now paid for the same material. In 1914, however, this same grade of steel was selling at $1.40 per 100 lb., the price increase in 5 yr., based on the above figures, being more than 200 per cent.

Indications do not point to further steel price decreases, the biggest factor preventing price reduction being the labor situation, both in the mining and rolling mill districts.

PAIGE BUILDING IMPROVEMENTS

DETROIT, June 21—The Paige-Detroit Motor Car Co. is spending $400,000 in plant equipment and other improvements which will permit an increase in production facilities of approximately 25 per cent. It applies to both the passenger car and truck divisions of the plant.

No new buildings are being built, but the new units completed for war work and containing approximately 66,000 sq. ft., are being utilized. The company expects to have the improvements completed and to be operating on an increased production schedule within 60 days.

The present capacity of the automobile department is 125 cars daily, while the truck department has facilities for 50 a day. The new arrangement will permit the manufacture of 175 passenger cars and 75 trucks daily.

The Paige company has been hard hit by a shortage of materials. During the month of May, 1500 passenger cars were produced, the daily production being approximately 55. From 3 to 10 trucks are turned out daily.

KELLY-SPRINGFIELD BUILDS

NEW YORK, June 24—To finance erection of a new plant at Cumberland, Md., the Kelly-Springfield Tire Co. is issuing $5,800,000 of 8 per cent preferred cumulative stock. The issue will be offered to both common and preferred shareholders at par ($100) and will be underwritten by a syndicate.

With completion of the first unit of the Cumberland plant, according to A. L. Scheuer, chairman of the board, the company's production will be materially increased over the combined output of the Akron and Wooster, Ohio, and Buffalo, N. Y., factories.

BOHNET READY FOR PRODUCTION

LANSING, MICH., June 18—The John Bohnet Co., which recently entered the truck body business, has completed alterations necessary for body production. The company, which utilized a part of the old Clark shops for its painting and all-season top departments, has leased the entire property and will occupy all floors of the old plant. By July 1 body production will begin.

This fall the company plans to erect a new plant on land on which it has options in another part of the city. While the company will move its body building activities to the proposed new factory building, the entire Clark property will be retained for the repainting department.

Stutz Pioneer Quits Office

Harry Stutz Retires as Active Head of Parent Company

NEW YORK, June 24—Harry C. Stutz, pioneer in the manufacture of the car which bears his name, will retire July 1 as active head of the Stutz Motor Car Co. of America. He will give up both the presidency and general managership, remaining in the organization merely as a member of the board of directors.

In the presidency Mr. Stutz will be succeeded by Allen A. Ryan, head of Ryan & Co., bankers, and vice-president of the Stutz concern during the past year. His successor as general manager has not yet been selected.

The reorganization, effected at the recent annual meeting, included the election of Frederick E. Gunnison of the directorate to the vice-presidency and the naming of George F. Lewis as secretary to succeed Kenneth R. Howard. William N. Thompson was re-elected treasurer.

Directors chosen, in addition to Messrs. Ryan, Stutz, Gunnison and Thompson, were: George H. Saylor, John J. Watson, Jr., and Hicks A. Weatherbee. The last named, the only new member of the board, succeeded Mr. Howard, who is connected with the Ryan banking firm.

Mr. Stutz, who organized the original Stutz company in Indiana, became head of the Stutz Motor Car Co. of America upon its incorporation in 1916.

Mr. Ryan said there would be no change in the manufacturing or sales policies of the Stutz concern as a result of the reorganization. Neither he nor his associates were aware of the future plans of Mr. Stutz.

INDIANA S. A. E. MEETS

INDIANAPOLIS, June 23.—The Indiana Section of the Society of Automotive Engineers held one of its summer meetings last week. It was attended by 91 members and guests. L. H. Pomeroy, formerly chief engineer of the Vauxhall Co., England, spoke on the difference between English and American manufacturing, and the engine of the future.

PACKARD INCREASES CAPITAL

DETROIT, June 26—Stockholders of Packard Motor Car Co. met to-day to vote on a plan authorizing an increase in the company's capital stock from $21,000,000 to $50,000,000.

Only $7,000,000 of 7 per cent preferred stock will be sold at this time. This will be underwritten by a New York syndicate. The $7,000,000 issue anticipates the retirement of $5,000,000 in gold notes due in October, and provides $2,000,000 working capital.

Under the new capitalization $30,000,000 will be common stock and $20,000,000 preferred stock. In 1915 sales totaled $15,000,000 and in 1919, $64,000,000.

26 Flying Fields Retained by U. S.

14 to Be Used for Storage—Present Proposed Disposition of Fields Shown

WASHINGTON, June 20—Twenty-six flying fields will be retained permanently by the Air Service of the United States War Department, and 14 will be retained temporarily for storage and other purposes. No fields are being abandoned or sold at present. Following is a table showing the present proposed disposition of the fields:

1. Owned by U. S.
2. Being purchased.
3. Retained under lease.
4. Retained temporarily for storage.
5. Retained temporarily.
6. To be abandoned.
7. Being sold.

*Purchased. Passed into hands of United States about June 15.

Note.—The Aerial Coast Defense Station, New Dorp, Staten Island, N. Y., was omitted from the list. This station is owned by the United States.

AVIATION APPROPRIATION INCREASED

WASHINGTON, June 21—The House Military Affairs Committee has increased the appropriation for the Army Aviation service to $55,500,000. Special provisions in the new Army bill allow $982,000 for the purchase of the Curtiss-Ellwood aviation plant at Buffalo, $3,260,000 for the purchase of the Dayton-Wright airplane plant at Dayton, $3,500,000 for the purchase of the dirigible landing field and hangars in Burlington County, N. J., and $470,000 for Rockwell Field, San Diego, Cal.

$35,000,000 FOR NAVAL AVIATION

WASHINGTON, June 20—The Senate Naval Affairs Committee to-day voted to allow $35,000,000 for naval aviation during the coming year. Secretary of the Navy Daniels yesterday asked for $36,000,000, but said he could get along on $35,000,000.

FRENCH AVIATION LOSSES

PARIS, June 1—From Aug. 4, 1914, to armistice day the losses of the French air service at the front were 1945 pilots and observers killed, 1461 missing and now assumed to be dead, and 2922 wounded. These losses cover the fighting zone only.

In the interior zone, which covers the lines of communication, schools, etc., the losses were 1927 pilots and observers. This gives a total loss for the French air service of 7,757 pilots or observers.

The French flying staff on Dec. 1, 1918, consisted of 12,919 men. The losses therefore represent 61 per cent of the total.

AIRCRAFT FOR EDUCATION

WASHINGTON, June 20—A joint resolution offered to Congress this week authorizes the Secretary of War to loan airplane engines, airplanes, aeronautic equipment and parts to educational institutions which maintain scientific departments. This equipment is to be loaned for educational purposes only under such regulations as may be prescribed by the Secretary of War. The resolution was referred to the Committee on Education and Labor.

Training Planes and Engines Sold

WASHINGTON, June 23—Eleven hundred Standard J-1 planes, 4608 Curtiss OX-5 engines and 1616 Curtiss JN-4 planes without engines have been sold by the War Department to the Curtiss Aeroplane & Motor Corp. for approximately 12 per cent of the original cost. The following table shows the types sold, with the approximate cost and selling price:

Type	No. sold	Approx. unit cost price	Unit sale price	Sale price in per cent of cost
SJ-1 plane	1,100	$4,750	$200	4
JN-4 plane	1,616	4,750	400	8
OX-5 motor	4,608	2,100	400	19

ONE ENGINE ON ORDER

WASHINGTON, June 20—All outside orders for airplane service engines have been completed, according to the War Department, except one order for a Hispano-Suiza 300-hp. engine. This original order was for 10,000, but 9500 have been cancelled, leaving 500 on order. Of these, 499 have been completed, leaving but one engine still on order, which is expected to be delivered this week.

Air Regulations for Flight and Passengers

Provisions for Number of Passengers, Landing and Starting, Sale of Gasoline and Oil

WASHINGTON, June 20—The Director of Air Service has issued regulations for flights in aircraft under the control of the Air Service and for carrying passengers, landing and taking-off from flying fields, and for the sale of gasoline and oil to pilots not in military service. Flights can be made:

(a) For the proper execution of any approved project of the Air Service, or of the Air Service in co-operation with any other branch of service or department of the government—special approval of this office to be secured in each case.

(b) For the demonstration of aircraft, and aircraft development to officers of the executive, legislative and judicial branches of the government.

(c) For the rapid transportation of military or civilian officials of the government, of messages or parcels in cases of urgent necessity and for the convenience of the government.

(d) For the assistance of stranded civilian aviators or where it is necessary for the saving of human life.

The following may be carried as passengers in aircraft under the control of the Air Service:

(a) Any person necessary to be carried as a passenger to accomplish the purpose of any of the flights authorized in Paragraph No. 1 above.

(b) Officers and enlisted men of the army, navy and marine corps, both active and reserve.

(c) Officers and enlisted men of foreign armies, as a courtesy when they are visiting the United States.

Aircraft Pilots

No person will be permitted to pilot aircraft under the control of the Air Service except regularly authorized Air Service pilots or bona fide student-pilots of the Air Service.

Persons operating aircraft who are not in the military service or who are not under the jurisdiction of the Air Service, will be permitted to use Government facilities at Air Service stations contingent upon their proper observation of the air and ground rules in force at the particular station in question, and subject to the discretion of the commanding officer thereof, as not interfering with the proper conduct of official business of his station, as follows:

(a) They may be permitted to land and take-off from flying fields.

(b) They may be permitted to place airplanes in government hangars over night or for a short time pending repairs.

The sale of gasoline, oil, spare parts, etc., or the furnishing of the labor of Air Service mechanics in any form to pilots not in military service is forbidden.

16,000 More Surplus Vehicles Possible

Likely to Be Turned Over to Various Government Departments

WASHINGTON, June 24—That there may be 16,000 more vehicles surplus above the 39,000 already so classified and distributed to Government Bureaus was indicated by testimony before the Senate Military Affairs Committee when C. W. Hare, Director of Sales, Colonel Fred Glover and others testified with regard to the disposition of surplus munitions.

Testimony showed that there were 64,334 trucks and 11,179 passenger cars in the Army, a total of 75,513. Of this number, 5676 cars and 33,485 truck, a total of 39,161, are held, and 5503 cars and 30,849 trucks, a total of 36,352, have been declared surplus and are being transferred to other Government Bureaus.

Colonel Glover stated that the temporary reserve of 16,000 additional vehicles is included in the 39,161 which are still held by the Army, and these may be turned over later as surplus, so that the army will retain from 18,000 to 22,000 vehicles. There are also 23,543 trailers which are to be divided into permanent and surplus quantities and disposed of.

The testimony also developed the sales of tanks, tractors and airplanes. Mr. Hare showed that through the Department of Sales considerably higher prices were being secured, and cited two 6-ton tanks which the Ordnance Department had expected to sell for scrap at $1,000. These tanks were sold for $3,000 each by the Director of Sales. Likewise, thirty 45 hp. Holt tractors, costing the Government $5,800 each, were to be distributed for less than $1,000 each by one of the army camps.

Clevelands Go to Agriculture Department

The Department of Sales took over the tractors and distributed them to other divisions of the War Department. Forty-eight Gray wide drive drum tractors, reported surplus by the Ordnance Department, costing the Government $105,000, were to be sold back to the Gray Tractor Company at $50,000. Negotiations by the Department of Sales increased the offer to $65,000. This offer was not accepted and the tractors were sold in part to the Department of Commerce and Bureau of Fisheries for use in the Arctics, and the remainder have been transferred to the Bureau of Public Roads. Twenty-eight Cleveland tractors, appraised by the Ordnance Department at $400 each, were offered for sale, and the sale was stopped by the Department of Sales, and all but two of these tractors turned over to the Department of Agriculture. The remaining two were sold for $600 each.

Letters introduced, combined with discussions, show that the War Department, which recently sold 4608 Curtiss OX-5 engines, 1616 JN-4 airplanes without engines and 1100 Standard J1 airplanes without engines, valued at $20,000,000, to the Curtiss Aeroplane & Motor Corp., Buffalo, for $2,720,000, had offered these to the entire aeronautical industry and was unable to secure bids from others than the Curtiss company. It was shown that before the sale was consummated contracts were carefully drawn up, and the approval of Major General C. T. Menoher, Director of Air Service, and Secretary of War Newton D. Baker, was secured.

General Menoher pointed out that there is no general market for airplanes or airplane engines, that the industry is in its infancy, that designs change rapidly and that consequently it was to the general welfare to sell these planes and engines to a reliable manufacturer to be overhauled and sold with his guarantee. The Standard Aeroplane Corp. also made bids on the material but their tentative offer wos not as high as that made by the Curtiss company.

Approximations of the surplus supplies still held by the various Bureaus show the total surplus valued at $62,000,000 held by the Aircraft Production Division of the Air Service, of which practically $60,000,000 worth remains to be sold; $85,000,000 worth held by the Division of Military Aeronautics, Air Service, of which more than $80,000,000 worth remains to be sold.

MACHINERY MANUFACTURERS MEET

NEW YORK, June 20—Time, labor and money saving benefits derived from the use of motor trucks, trailers and kindred equipment in the handling of materials were described by J. M. Van Harlingen, of the Republic Motor Truck Co., in an address before the recent annual meeting of the Material Handling Machinery Manufacturers' Association. He told how the Fiske Rubber Co. had synchronized its factory transportation by using industrial trucks, trailers, elevators, etc., handling all of this under the management of one transportation superintendent, with the result that the first year the direct economies showed an actual saving of over $50,000 in payroll and plant maintenance costs, to say nothing of the great advantages which accrued to the plant through better delivery, and facilitated movement of all raw materials and finished products.

United States Senator Burton of Ohio urged attention of the members to development of transportation and other devices to hasten the loading and unloading of ships. He cited the profit which might be derived through the saving of only one day for every trip of every ship and urged the prompt installation of any modern means which would help speed up the return of ships to home ports, this of itself helping to offset the shortage of world shipping tonnage which has resulted from the activity of the German submarine war program. He termed expansion of port facilities the controlling factor in upbuilding the American merchant marine.

France Encouraging Peace-Time Aviation

American Aviation Mission to Suggest Development in U. S.—To Visit England

PARIS, June 21 (*Special Cable*)—Its work in France practically completed, the American Aviation Mission, headed by Assistant Secretary of War Benedict Crowell, left Paris this week, the main party proceeding to England, while some of the members, with Howard E. Coffin, representing the Council of National Defense, went to Italy.

The commissioners were impressed with the fact that the French government is giving more encouragement to airplane manufacturers to continue in peace-time business than is the case in the United States.

The mission has been in close touch with all the French aircraft producers and with various French government departments, gathering material for a report to be presented to Congress, suggesting means of developing commercial aviation in the United States.

The mission, having gone abroad without the technical advisers, whose proposed trip was cancelled because of lack of American government authorization, has done no work on standardization, though it received from British aviation authorities in France a full report on the standards situation as it exists in France.

Mr. Coffin's section, returning from Italy, will join Assistant Secretary Crowell and his associates in England, the entire party having planned to sail for home in about two weeks.

BUREAU OF MANUFACTURERS

WASHINGTON, June 24—The establishment of a Bureau of Manufacturers in this city by Congress was proposed yesterday by Senator Sheppard. The Bureau, as proposed, is to study manufacture in all forms and distribute information as a result of the investigations.

In proposing the resolution Senator Sheppard declared that Government Departments are devotel to agriculture, commerce and labor but there are no departments established for manufacture. The great quantities of basic raw materials, which are being shipped abroad, should be converted into finished products in this country. This, he said, can only be done by the development of our manufacturing facilities.

ENLARGING MARMON PLANT

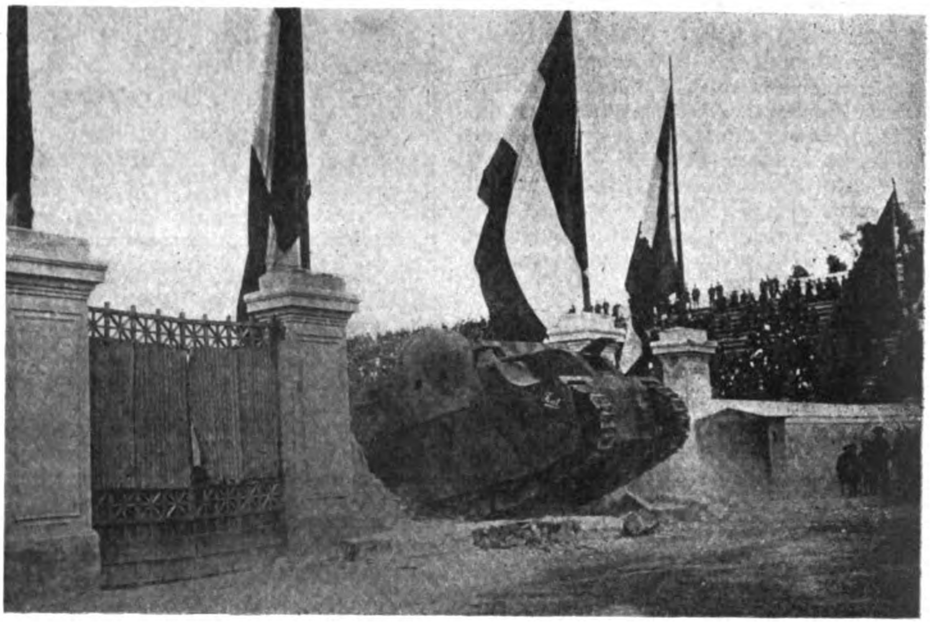
NEW YORK, June 26—The Nordyke & Marmon Co., Indianapolis, is negotiating with underwriters to issue at once $2,500,000 bonds to finance construction of additions to its factory, putting the plant on an extensive production basis. It is believed that the bonds will be put out next week.

Standards Formulated for Women in Industry

U. S. Department of Labor Regulates Hours, Wages and Occupations for Women

WASHINGTON, June 23—Standards for the employment of women in industry have been formulated by the United States Department of Labor, regulating the hours of labor to no more than 8 per day, providing for equal wages with men, prohibiting the employment of women in poisonous occupations, prohibiting home work, and providing for representation for women in organization necessary for collective bargaining.

Following are the complete standards recommended:



A contrast of the old and the new. Recently a war exhibition was arranged for the benefit of the Italian royalty in the Coliseum. There were trenches, huts, wire entanglements and other equipment. Finally came a tank, which destroyed many of these and then turned to leave the grounds, but instead of passing through the gate broke down a part of the wall and went over the ruins

I. Hours of Labor

1. Daily hours—No woman shall be employed or permitted to work more than eight hours in any one day. The time when the work of women employees shall begin and end and the time allowed for meals shall be posted in a conspicuous place in each workroom, and a record shall be kept of the overtime of each woman worker.

2. Half holiday on Saturday—The half holiday on Saturday should be the custom.

3. One day of rest in seven—Every woman worker shall have one day of rest in every seven days.

4. Time for meals—At least three-quarters of an hour shall be allowed for a meal.

5. Rest periods—A rest period of 10 minutes should be allowed in the middle of each working period without thereby increasing the length of the working day.

6. Night work—No woman shall be employed between the hours of 10 p. m. and 6 a. m.

II. Wages

1. Equality with men's wages—Women doing the same work as men shall receive the same wages, with such proportionate increases as the men are receiving in the same industry. Slight changes made in the process or in the arrangement of work should not be regarded as justifying a lower wage for a woman than for a man unless statistics of production show that the output for the job in question is less when women are employed than when men are employed. If a difference in output is demonstrated, the difference in the wage rate should be based upon the difference in production for the job as a whole and not determined arbitrarily.

2. The basis of determination of wages—Wages should be established on the basis of occupation and not on the basis of sex. The minimum wage rate should cover the cost of living for dependents and not merely for the individual.

III. Working Conditions

1. Comfort and Sanitation—State labor laws and industrial codes should be consulted with reference to provisions for comfort and sanitation. Washing facilities, with hot and cold water, soap, and individual towels, should be provided in sufficient number and in accessible locations to make washing before meals and at the close of the workday convenient.

Toilets should be separate for men and women, clean and accessible. Their numbers should have a standard ratio to the number of workers employed. Workroom floors should be kept clean. Dressing rooms should be provided adjacent to washing facilities, making possible change of clothing outside the workrooms. Rest rooms should be provided. Lighting should be so arranged that direct rays do not shine into the workers' eyes. Ventilation should be adequate and heat sufficient. Drinking water should be cool and accessible, with individual drinking cups or bubble fountain provided. Provision should be made for the workers to secure a hot and nourishing meal, eaten outside the workroom, and if no lunch rooms are accessible near the plant a lunch room should be maintained in the establishment.

2. Posture at work—Continuous standing and continuous sitting are both injurious. A seat should be provided for every woman employed, and its use encouraged. It is possible and desirable to adjust the height of the chairs in relation to the height of machines or work tables, so that the worker may with equal convenience and efficiency stand or sit at her work. The seats should have backs. If the chair is high, a foot rest should be provided.

3. Safety—Risks from machinery, danger from fire, and exposure to dust fumes, or other occupational hazards, should be scrupulously guarded against by observance of standards in State and Federal codes. First-aid equipment should be provided. Fire drills and other forms of education of the workers in the observance of safety regulations should be instituted.

4. Conditions needing correction—Work is more efficiently performed by either men or women if healthful conditions are established. It is usually possible to make changes which will remove such hazards to health as the following:

a. Constant standing or other posture causing physical strain.
b. Repeated lifting of heavy weights, or other abnormally fatiguing motions.
c. Operation of mechanical devices requiring undue strength.
d. Exposure to excessive heat or excessive cold.
e. Exposure to dust, fumes, or other occupational poisons, without adequate safeguards against disease.

5. Prohibited occupations—Women must not be employed in occupations involving the use of poisons which are proved to be more injurious to women than to men, such as certain processes in the lead industries.

6. Work dress—Work dresses with caps and comfortable shoes are desirable for health and safety in occupations for which machines are used or in which the processes are dusty.

IV. Home Work

No work shall be given out to be done in rooms used for living or sleeping purposes or in rooms directly connected with living or sleeping rooms in any dwelling or tenement.

V. Employment Management

1. Hiring, separations, and determination of conditions—In establishing satisfactory relations between a company and its employees a personnel department is important, charged with responsibility for selection, assignment, transfer, or withdrawal of workers and the establishment of proper working conditions.

2. Women in supervisory positions—Where women are employed, a competent woman should be appointed as employment executive with responsibility for conditions affecting women. Women should also be appointed in supervisory positions in the departments employing women.

3. Choice of occupation—The opportunity for a worker to choose an occupation for which she is best adapted is important in insuring success in the work to be done.

VI. Co-operation of Workers in Establishing Standards

The responsibility should not rest upon the management alone to determine wisely and effectively the conditions which should be established. The genuine co-operation essential to production can be secured only if provision is made for the workers as a group, acting through their chosen representatives, to share in the control of the conditions of their employment. In proportion to their numbers women should have full representation in the organization necessary for collective bargaining.

VII. Co-operation with Official Agencies

The United States Government and State and local communities have established agencies to deal with conditions of labor, including standards of working conditions, wages, hours, employment, and training. These should be called upon for assistance, especially in the difficult problems of adjustment in the period of reconstruction following the war.

PROBE WAR DEPARTMENT

WASHINGTON, June 20—The Congressional Committee named by the House of Representatives to investigate the expenditure of $16,000,000,000 has divided itself into five sub-committees to make the inquiry. No date has been fixed for the beginning of investigations.

The special Committee on Aviation comprises Congressman Frear, chairman, and Congressmen Magee and Lea. The Committee on Quartermaster's supplies comprises Congressman Reavis, chairman, and Congressmen MacGregor and Donovan. The Committee on Ordnance includes Congressman Graham, chairman, and Congressmen Jefferis and Garrett. The Committee on Expenditures in Foreign Countries includes Congressman Johnson, chairman, and Congressmen Bland and Flood.

MERWIN HEADS NATIONAL TIRE

EAST PALESTINE, OHIO, June 23—C. L. Merwin was elected president of the National Tire & Rubber Co. at the annual meeting of the board of directors. Other officers are: Vice-president and general manager, S. L. Warner; secretary, C. W. Helman; treasurer, R. B. Taggart. C. E. Miley will become vice-president and general sales manager on July 1. Mr. Miley has been associated with the McGraw Tire & Rubber Co. for the past ten years.

C. E. Albright has been made Pacific Coast field manager of the Acason Motor Truck Co. of Detroit. He will work under Dan Gilkey, Pacific Coast manager.

Carlos Grant, of Concepcion, Chile, has been made resident export manager in charge of export sales in most of the South American countries for the Saxon Motor Car Corp.

A. L. Ditter, former general manager of the Northwest Body Co., Minneapolis, has been appointed sales manager for the Field Manufacturing Co., Owosso, Mich.

C. R. Mabley has been appointed Michigan sales manager for the S. K. F. Industries, Inc. He will open headquarters in Detroit.

C. S. Coler has been appointed manager of the educational department of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., succeeding C. R. Dooley, who resigned.

Hilton W. Sofield has been elected vice-president and general manager of the Commercial Car Unit Co., Philadelphia. He started with the company as service manager in 1917. He has been responsible for the Keystone 2-ton truck added to the company's line of Truxton and Unitrux units.

George S. Shugart has been appointed general sales manager of the United States Tire Co., succeeding J. C. Weston, whose resignation becomes effective July 1. Mr. Shugart, who has been in the U. S. Tire ranks for 23 years, goes to his new office from the sales managership of the New York branch, which he assumed after 12 years of similar work with headquarters in Chicago.

CANADIAN RUBBER ELECTS

MONTREAL, June 20—Sir Charles B. Gordon, K. B. E., and Lieut.-Col. Herbert Molson, M. C., were elected to the board of directors of the Canadian Consolidated Rubber Co., Ltd. The board of directors of the company, besides the newly elected members, includes: Sir Mortimer Davis, E. W. Nesbitt, J. B. Waddell, Victor E. Mitchell, K. C., W. A. Eden, R. E. Jamieson, A. D. Thornton, H. Wellein, Col. Samuel P. Colt, Charles B. Serger, Homer E. Sawyer, J. Newton Gunn and Elisha S. Williams.

100 FORDSONS A DAY

DETROIT, June 20—The production of Fordson tractors is approximating 100 per day.

Men of the Industry

Changes in Personnel and Position

HANCH TO MANAGE MAXWELL-CHALMERS

DETROIT, June 21—C. C. Hanch, for years treasurer of the Studebaker Corp., has resigned to become general manager of all Maxwell-Chalmers interests. At the outbreak of the war Mr. Hanch was made chief of the automobile products section of the War Industries Board. Since the armistice he has been in Europe investigating export conditions for the National Automobile Chamber of Commerce. Prior to joining the Studebaker Corp. in 1915, he was for 19 years treasurer of the Nordyke-Marmon Co. In recent years he was secretary of the National Chamber of Commerce and is at present a director of that body.

O. E. Szekely, chief engineer and production manager of the tractor department of the Velie Motors Corp., has severed his connection with that company to take over the engineering and production end of the Grid-Iron-Grip Co., Rock Island, Ill., maker of track-laying shoes for tractors and trucks. In addition a general engineering laboratory will be operated as the O. E. Szekely Co. and will furnish drawings and designs in all automotive lines.

F. R. Mead, recently discharged as captain in the Ordnance Department, where he acted as head of the Gage Section Inspection Division, has been appointed Eastern representative of the Wilton Tool & Manufacturing Co., Boston.

George T. Bryant, sales manager of the Hide Leather & Belting Co., Indianapolis, who spent several months in Europe during the first part of the year investigating trade conditions, will leave for a second trip on the Nieuw Amsterdam, sailing from New York on July 2. He will visit France, Switzerland, Belgium, Holland, Denmark, Norway, and Sweden, and plans to return about Nov. 1.

REPRESENTATIVES FOR FOREIGN COUNTRIES

JEANNETTE, PA., June 26—D. D. F. Yard, sales director of the export division of the Pennsylvania Rubber Co., will sail from San Francisco on July 1 for Honolulu, en route to Australia, Straits Settlement, New Zealand, China, Japan, India, and South Africa. R. W. Palm, South American representative, will sail on the same date for Latin America, where the company has agencies. The export office in the Woolworth Building, New York, opened recently, will be in charge of F. B. Beck in the absence of Mr. Yard.

RYAN HEADS STUTZ

NEW YORK, June 23—Allan A. Ryan, head of Ryan & Co., bankers, and formerly vice-president of the Stutz Motor Car Co. of America, was elected president at the annual meeting last week, succeeding Harry C. Stutz.

At the company's offices it was said that Mr. Stutz is still in active charge of the business, but information was unobtainable as to whether he would continue in that capacity.

Other officers elected were: Vice-president, Frederick E. Gunnison; treasurer, William N. Thompson, re-elected; secretary, George F. Lewis, succeeding Kenneth R. Howard.

Directors elected, in addition to officers, were: Harry C. Stutz, George H. Saylor, John J. Watson, Jr., and Hicks A. Weatherbee, succeeding Mr. Howard.

PERRY REMAINS WITH FORD

LONDON, June 10—Sir Percival Perry, who resigned recently as managing director of the Ford interests in Great Britain, will remain with the organization, dividing his time between the London offices and the tractor factory at Cork, it is said in trade circles here.

The factory, delayed in completion by war conditions, is making castings, but no finished products have yet appeared. Work also is under way on the Ford garage at Brook Green, Hammersmith, London, W.

CANADIAN OVERLAND OFFICIAL

TORONTO, ONT., June 20—J. F. Mackay, formerly business manager of the Toronto *Globe* and until lately treasurer of the Russell Motor Car Co., has been appointed secretary-treasurer of Willys-Overland, Ltd., West Toronto.

In his new work Mr. Mackay will be associated with T. A. Russell, president of Willys-Overland, who is also president of the Russell Motor Car Co. Mr. Mackay joined the Russell company last August.

PAIGE APPOINTMENTS

DETROIT, June 23—Frederick L. Jewett has been elected first vice-president of the Paige-Detroit Motor Car Co. Other promotions and appointments were as follows: Vice-president, manufacturing division, W. A. Wheeler; vice-president in charge of passenger car sales, Henry Krohn; vice-president in charge of truck sales, Charles S. Pike; vice-president, purchasing division, Thomas Bradley; vice-president, engineering division, Andrew Bachle; chief engineer, G. C. Mather; production manager, J. V. Quinlan; general superintendent, George Petersen; sales manager of the passenger car division, C. B. Gaunt, and sales manager of the truck division, Frank E. Caulk.

R. Jackson Jones has been appointed district sales supervisor of the Traffic Motor Corp., St. Louis. He returned recently from 15 months' service with the Canadian army in the British West Indies.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

DUESENBERG CARS

ELIZABETH, N. J., June 20—The Duesenberg Motors Corp. is considering entrance on a large scale into the field of passenger car manufacture. Though no decision has been reached, the company still being under government control, E. P. Decker, general manager, stated that a tentative plan was being worked out for the projected expansion. Until a settlement is effected for War Department contracts pending, Mr. Decker said, the project would remain in abeyance.

CANADIAN PLANT FOR STICKNEY

PETERBORO, ONT., June 20—The Stickney Motors, Ltd., St. Paul, Minn., will take over the cordage works recently vacated by the Renfrew Mfg. Co. and manufacture farm tractors, motor trucks and gasoline engines, employing for nine months each year for ten years a minimum of 50 employees.

PERFEX DISCHARGED

RACINE, WIS., June 21—The Perfex Radiator Co. was discharged from bankruptcy by Judge F. A. Geiger of the Federal Court at Milwaukee on June 18, after a hearing on the application of the company in which it developed that arrangements have been effected to pay creditors 100 per cent of claims.

An involuntary petition in bankruptcy was filed against the company March 28, and Julius J. Goetz, Milwaukee, was appointed trustee and later made receiver with authority to continue operations as before. The schedules filed on the petition admitted liabilities of $227,319 and claimed assets of $1,300,000. The discharge from bankruptcy was granted after creditors who filed the involuntary petition indorsed the application and consented to the dismissal of the proceedings.

QUALITY TIRES TAKEN OVER

ELYRIA, OHIO, June 23.—The Long-Wear Rubber Co. has taken over the production and sales of the Quality Tire & Rubber Co., Anderson, Ind. This adds a daily production of 200 casings and 2000 tubes. Both factories will be under the supervision of Frank W. O'Brien, general manager of the company, with headquarters here. Plans for expansion call for the production of 20,000 pneumatic and solid tires daily.

NEW CANADIAN TIRE CONCERN

KITCHENER, ONT., June 23—The Ames-Holden-McCready Co., wholesale shoe manufacturer, has completed arrangements for the formation of a tire manufacturing concern at Kitchener, the new enterprise to be known as the Ames Holden Tire Co., Ltd., and will, it is understood, begin building operations at once.

The new company will have a capitalization of $1,000,000 bonds and $2,000,000 common stock. The board of directors will include T. H. Reider and D. Lorno McGibbon.

MAXWELL-CHALMERS PLANT

NEW YORK, June 23.—The plans for the $10,000,000 plant to be erected for the recently merged Maxwell-Chalmers interests call for 11 manufacturing units and a loading dock. A new office building and power house will also be erected. The machine shop will be the largest. It will be 1-story, 200 by 1,000 ft. The dimensions of the other buildings are as follows: Two storage buildings for assembly parts and finished cars, 4 stories, 100 by 800 ft.; axle plant, 1-story, 150 by 600 ft.; heat treat plant, 1-story, 200 by 300 ft.; engine assembly plant, 1-story, 200 by 300 ft.; pressed steel plant, 1-story, 250 by 600 ft. The loading dock will be 100 by 800 ft.

A body plant will be erected later. Plans for this unit call for a structure 4 stories high, 400 by 600 ft. The two storage buildings will have space for 8,000 unfinished cars and 3,000 finished products. All buildings will be of concrete, brick and steel.

The pressed steel plant, which consists of several 1-story buildings, will gradually be razed, and the buildings of the new plant will take their place.

CONTINENTAL EXPANSION PLANS

DETROIT, June 23.—The Continental Motors Corps. will increase production at both the Detroit and Muskegon plants at once. Every effort will be made to reach capacity production within the next 60 days. The Detroit plant is manufacturing 300 engines daily, and the Muskegon plant 350.

Expansion plans calling for doubling the floor area and increasing production facilities of the Muskegon plant will be put into effect at once. Within the next 2 years the Muskegon plant will be doubled in size. The first units to be built include a power plant, 560 by 180 ft., additions to the engine department, a drop forge plant, and an addition to the screw machine department.

Additional units will be erected on 25 acres of land which the company will reclaim from Lake Michigan. One thousand more men will be employed, and the new plant will have a capacity of approximately 1,000 engines daily.

LION MOTOR PLANT PURCHASED

ADRIAN, MICH., June 21—The old Lion Motor Co.'s site has been purchased by the United Electric Mfg. Co., and an engine plant will be erected soon at a cost of $100,000. The Lion plant has been unoccupied for 7 years. The United Electric Mfg. Co. began operations 3 years ago.

SAVOLD TO OPEN PLANTS

NEW YORK, June 23—The Savold Tire Corp. has completed or has in process incorporation in 21 states. The concern, which has patented processes for rebuilding tires, will operate factories in all the 21 states, it was said at the headquarters here. One of several plants to be opened in New York City will be in operation within a few weeks.

AUTO BODY BUYS ENGINE PLANT

LANSING, June 20—The Auto Body Co. has purchased the plant of the Acme Engine Co. and has obtained a 10-year lease on the land on which the building stands. The Acme Engine Co., reorganized from the Peerless Engine Co., went out of business at the start of the war, most of its machinery being purchased by the Government.

NOVO ENGINE BUILDING

LANSING, June 20—Work has been started on two new buildings for the Novo Engine Co., which are to be ready for occupancy within 40 days.

KALAMAZOO MOTORS ENLARGES

KALAMAZOO, MICH., June 20—The Kalamazoo Motors Corp. has let contracts for the erection of a machine shop having 2,000 sq. ft. of floor space, loading docks and a building for stock purposes. These additions will double the capacity of the plant and permit assembly of from 125 to 150 trucks a month.

REPLACES BURNT BUILDING

DETROIT, June 20.—The Commerce Motor Car Co. had a $100,000 fire Friday, but it is said that production would not be affected in any way. The flames were confined to the paint department. The loss was fully covered by insurance. A new structure to take the place of the destroyed paint shop will be started as soon as the debris is cleared away.

BRISCOE TRIPLES PRODUCTION

JACKSON, MICH., June 20—The Briscoe Motor Corp. will build plant additions which will permit triple production. The present output of 70 cars daily will be increased to 250 cars. The additional units will be ready for production in about 7 months. The company is putting night shifts at work in an effort to increase its output. It has 1300 persons on the pay-roll, 300 of whom are women, and is proposing to go after the truck business, being in production of a 1½ ton truck.

COMPANY NAME CHANGED

ROCKFORD, ILL., June 23—The Bergie National Spark Plug Co. has changed its name to the National Spark Plug Co. to correspond with the name of its product, National spark plugs. There will be no change in the management of the company.

Detroit Needs Men and Houses

Skilled and Common Labor in Demand—Radicals Cause Trouble

DETROIT, June 20—Detroit automotive industries need thousands of workers, but they dare not bring more men to the city because of inadequate housing facilities. Following the signing of the armistice and temporary suspension of manufacturing to permit reconstruction work, a large labor surplus developed. Fifty per cent of all men out of work at that time left Detroit, a fact which aided materially in decreasing the serious surplus.

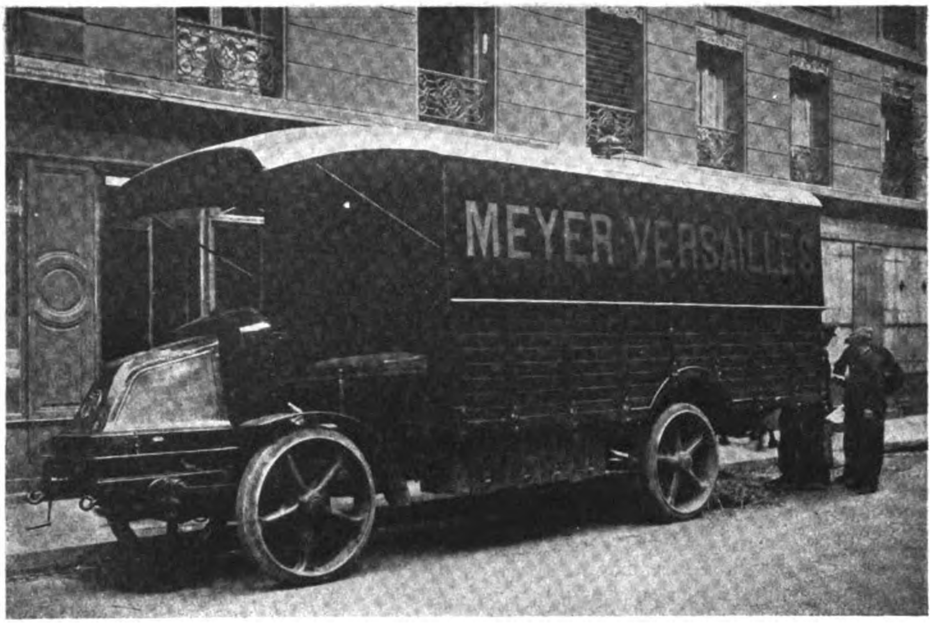
With the resumption of manufacture the surplus that existed here after the exodus of its war workers was quickly assimilated by the industries. As production increased a shortage soon developed, and the Detroit Employers' Association took action to bring more workers into Detroit.

For 3 months this association has brought approximately 2000 men into Detroit every week. Two weeks ago, however, the housing situation became so critical that the importation of workers was brought to a halt. Every available dwelling has been sold or rented, hotels, apartments and rooming houses filled up, and in most cases there is a waiting list.

Hundreds of new homes are being built here, but the number is inadequate. House-building associations have been formed and work on thousands of structures will be started at once, but it will be early winter before the results of this housing campaign bring relief. It is conservatively estimated that the city is short from 30,000 to 50,000 homes.

The housing situation has had a very detrimental effect upon labor conditions. Of the thousands of men brought here within the last 3 months, fully 60 per cent left town within 2 weeks, it is estimated. There has been considerable labor trouble here. A canvass of 115 metal trade industries shows that all have experienced from one to ten strikes during the last 3 months. Most of the trouble was confined to single departments, although in some cases the entire plant was forced to shut down.

The demand for men naturally brought many undesirables. This radical element is responsible for the labor unrest here. A remarkable feature in many strikes recently is the fact that one or two men usually caused the trouble. In the case of the L. A. Young Industries, 700 workers walked out as the result of the efforts of one individual. The employees were averaging 75 cents an hour and working an 8-hr. day. The disgruntled worker appealed to the union, cited many alleged grievances and asked that a strike be called. The union investigated and decided against a strike, whereupon the agitator and a handful of fellow radicals called a mass meeting of the employees, and 700 men quit their jobs the next day.



The first motor-driven furniture removal van to go into service in France. The chassis is a Latil 4-wheel drive

While production was badly cut for several days, the company was quick in getting back into operation, and within 2 weeks most of the men had returned to their jobs under old conditions and were apparently satisfied.

At the Studebaker factory 1200 workers at Plant No. 3 were out 10 days, at the end of which time they decided that the issues involved were too trivial to merit a continuance of the strike; so they went back to work. The trouble here was brought about by less than a dozen men.

In the Timken-Detroit Axle case the whole force walked out, and the strike is still in effect. The company is getting back into fair production, hundreds of its men have returned to their jobs, and vacancies are being filled. An unusual feature of this strike lies in the fact that men making as high as $2.35 an hour struck in sympathy and have been idle for 5 weeks.

The Michigan Malleable Iron Works is operating with about one-half its force. The Bowen foundries are not yet back in full production. The situation at both of these plants is rapidly clearing, however. The general foundry strike has fizzled out and all of the gray iron foundries are again at 100 per cent production.

The shortage is of highly skilled and common labor. There is no shortage of semi-skilled labor. In fact, Detroit has always found plenty of semi-skilled men available. The common labor situation is the most critical, and the employers' association is seeking a remedy. It is fighting the immigration bill now before Congress, which, if it passes, will bar immigration into the United States for a period of 4 years. The association holds that it is bad enough to have European countries bar its citizens from entering the United States without the United States throwing up an effective barrier on this side of the ocean. Thousands of foreigners, mostly of the common labor class, are returning to their native lands, and this exodus is already felt here.

Wages in Detroit are higher than ever. Common labor is making from 45 to 55 cents an hour in the shops, and from 60 to 65 cents an hour in the open. Skilled and semi-skilled trades are drawing from 60 to $2.35 an hour, the latter rate being paid to heavy hammer men who work on a piece rate basis.

RICKENBACKER CELEBRATION

LOS ANGELES, June 20—A three-day Rickenbacker celebration will be held here to-morrow, Sunday and Monday, opening on the first day with a large street parade. Sunday, Capt. Rickenbacker will be the guest of honor at an Elks' annual barbecue and will receive a gift from members, and on Monday a reception will be held in his honor in the Shrine Auditorium, when he will be presented with a gift from the people of Southern California.

SHEEPSHEAD PRIZES ANNOUNCED

NEW YORK, June 23—The contest board of the Automobile Association of America announced to-day that the purse for the 100-mile event at Sheepshead Bay July 4 will be $100,000. A $3,000 prize is offered the winner of the special race.

DETROIT SHOW IN MARCH

DETROIT, June 23 — The Detroit Automobile Dealers' Association, at its regular weekly meeting, decided to hold the annual automobile show some time in March.

ESSENKAY ADDITION

CHICAGO, June 23—The Essenkay Products Co has added a 5-story building to its factory.

MOTOR VEHICLES ON ORDER

WASHINGTON, June 24—Motor vehicle orders on May 31, 1919, were $4,077,000 as compared with $416,498,000 on Nov. 11, 1918, showing that about 1 per cent of the orders which were outstanding on the day the armistice was signed, remain for completion. Of the total orders placed, 67 per cent were cancelled and 32 per cent were delivered.

The liquidation of $215,434,000 worth of air service contracts out of a total of $268,400,000 makes a saving of 80 per cent.

PLANES FOR SOUTH AMERICA

NEW YORK, June 23—To develop a South American market for its land and seaplanes, the Curtiss Aeroplane & Motor Corp. will send a mission of aviators and mechanics, together with a number of demonstration machines, to Buenos Aires and Rio de Janeiro on July 1. C. W. Webster, supervisor of sales for South America, will be in charge.

AIRCRAFT LINEN SOLD

NEW YORK, June 23—Cable advices from London announce the sale of the entire linen stock of the Aircraft Equipment Section of the British government, a total amount of 30,000,000 yds., to Leonard J. Martin of the London Mineries. The linen, used in covering airplane wings, represents three-fifths of a year's output of the Belfast looms.

GLOVER TO RESIGN

WASHINGTON, June 24—Colonel Fred J. Glover, who prior to the war was associated with the Emerson-Brantingham Co., and who, during the war, served as Chief of the Motor Vehicle Section, Quartermaster Department, and later as Assistant Director of Sales, will resign on July 1 to enter private business activities, which will be announced later.

STEEL PRODUCTS BUYS PLANT

DETROIT, June 18—The Steel Products Co. of this city and Cleveland has acquired the plant of the Parker Rust Proof Co. of America. The property comprises approximately 4½ acres, on which there is a main building and three other structures, giving a combined floor area of about 65,000 ft. The value of the property is estimated at $250,000.

The purchaser is to take possession as soon as the Parker Rust Proof Co. vacates the premises. The latter is to continue its operations in another plant.

ACME FOREIGN REPRESENTATION

CADILLAC, MICH., June 23—The Acme Motor Truck Co. will be represented in Denmark, Norway, Sweden and Finland by the Aktieselkabet Autocar Co., Copenhagen, Denmark. Frantz Nehammer is president of the new company. Gmo. Verduzco & Co., Avenida, Jaurez, is the Mexican representative for the company.

One of the motor lorries photographed outside Electric House, Westminster, on Saturday. These are being used to help relieve the shortage of motor buses, which are at present inadequate

FOUNDRY COMPANIES MERGE

CLEVELAND, June 22—The Acme and the Palmer & De Mooy Foundry Co. have been merged into a $400,000 company and will operate under one roof at the Acme Foundry Co.'s plant after July 1. The Acme plant will be enlarged and new machinery installed. The Palmer & De Mooy Foundry Co. was organized 37 years ago. For a number of years it has been under the active management of W. B. Greene, secretary and treasurer. The Acme Foundry Co. was organized 20 years ago and has been managed by William Greenbaum, secretary, since its organization. The new company will be under the management of W. B. Greene who will act as president of the concern.

DEFIANCE MACHINE EXPANDING

DEFIANCE, OHIO, June 24—Work on the new foundry building of the Defiance Machine Works is about to start. The company will make other expansions rapidly. It is hoped to have 300 additional men at work in the shop by the middle of July. To accommodate the new workers, Defiance is preparing to start a home-building campaign. There is a great shortage of homes here.

ENGINEERING CO. CAPITAL

MOLINE, ILL., June 20—The capital stock of the Root & Van Dervoort Engineering Co. has been increased from $1,346,200 to $7,500,000. Of the issues under the new capitalization, $2,500,000 is to be common and $5,000,000 in the form of 8 per cent preferred stock. Increased capitalization will in no way affect control of the business. The board of directors will be increased from 7 to 9 members. The new capital will enable the company to increase its manufacturing facilities. New model cars are being developed.

AMERICAN RIM PARTS SCARCE

LONDON, June 18—Frequent satisfied inquiries for replacement of parts from a large number of users of American cars equipped with Stranweld or Baker detachable rims show that these lines are inadequately represented in Great Britain.

ROBINSON INITIAL PAYMENT

DETROIT, June 24—The Security Trust Co., trustee in bankruptcy, has sent to persons with approved claims against the Robinson Machine Co. checks covering an initial payment of 10 per cent. It is expected that a subsequent payment of a like amount will be made when the machine company's war contract claims have been closed up. The company's liabilities aggregated $175,000.

FOREIGN TRADE OPPORTUNITIES

WASHINGTON, June 20—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has received requests for automobile or parts agencies of business from individuals and companies in foreign countries. For further information address the Bureau of Foreign and Domestic Commerce and specify the Foreign Trade Opportunity number.

Calendar

SHOWS

Aug. 30-Sept. 6—Minnesota. State Fair.

Sept. 1-6 — Indianapolis, Ind. State Fair. Cars and Accessories, Indianapolis Automobile Trade Assn., John B. Orman, Manager.

Sept. 13-20—Cincinnati, O. Ninth Annual, Music Hall, Cincinnati Automobile Dealers' Assn., H. K. Shockley, Manager.

Sept. 15-20 — Springfield, Mass. Eastern States Exposition.

*Oct. 9-19—Paris. Grand Palais, International Automobile Mfrs. Congress.

Nov. 7-16—London. Olympia Motor Car Exhibition—Society of Motor Mfrs. and Trades.

December — Brussels. International Automobile Mfrs. Congress.

Jan. 3-10 — New York, N. Y. Grand Central Palace, National Automobile Chamber of Commerce, S. A. Miles, Manager.

Jan. 24-31—Chicago, Ill. Coliseum, Cars; Drexel Pavilion, Trucks; National Automobile Chamber of Commerce, S. A. Miles, Manager.

January — New York. International Automobile Mfrs. Congress.

February — Chicago. International Automobile Mfrs. Congress.

Feb. 23-Mar. 6 — Birmingham, Eng. British Industries Fair.

TRACTOR SHOWS

July 14-19—Wichita, Kan. Automotive Committee of National Implement Assn.

July 28-29—Columbus, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 1-2 — Piqua, O. Tractor show in charge of Prof. H. C. Ramower, head of agricultural engineering department of Ohio State University.

Aug. 18-22—Aberdeen, S. D. Sectional Tractor Demonstrations.

October—Ottawa, Ont., Can. Interprovincial Plowing Match and Tractor Demonstration.

CONTESTS

July 4—Hohokus, N. J. Dirt Track Event.

July 4—Tacoma, Wash. Annual speedway races.

July 4—Atlantic City, N. J.—Airplane races—Aeronautic Convention.

July 4—Sheepshead Bay, L. I. Speedway race.

July 19—Uniontown, Pa. Speedway race.

*Aug. 15 — Middletown, N. Y. Dirt track event.

*Aug. 22-23—Elgin, Ill. Road race.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Sept. 27—Allentown, Pa. Dirt track event.

*Oct. 1—Cincinnati, O. Speedway race.

*Oct. 4—Trenton, N. J. Dirt track event.

*Oct. 11—Danbury, Conn. Dirt track event.

*Tentative dates.
†Sanctioned.

CONVENTIONS

June 16-19—Detroit. American Society of Mechanical Engineers spring meeting, Hotel Statler.

June 23-28—Ottawa Beach, Mich. S. A. E. Mid-summer Meeting.

July 9-10—Buffalo. Motor and Accessory Mfrs. Assn. Mid-summer convention.

Sept. 22-24—Philadelphia. Annual Convention, National Association of Purchasing Agents. Bellevue - Stratford.

May 12-15, 1920—San Francisco. Seventh National Foreign Trade Convention.

January — Washington. Pan-American conference.

TRACTOR SALES IN CANADA

WINNIPEG, CAN., June 20—In 1906, 237 tractors were sold in western Canada. In 1907 the sales were 580. In 1908 the sales were around 660. In 1909 there were not quite 600, but in 1910 they went to over 1500 In 1911 something over 1700 were sold. In 1912, 3700; 1913, 4600; 1914, 4200; 1915, 4400, and in 1916 they barely passed the 5000 mark. In 1917, 6400 machines were sold, and in 1918 approximately 7300.

There were in use up to Nov. 1, 1918, in western Canada, 19,777 tractors. Of the number sold in 1918, 1115 were Fordsons. The gas tractors in use were divided as follows:

Saskatchewan	11,105
Manitoba	3,655
Alberta	5,017

There were up to the first of the year approximately 219,000 farms of 160 acres and over divided as follows:

Saskatchewan	99,341
Manitoba	67,490
Alberta	51,663

In Saskatchewan there were up to Nov. 1, 1918, 8.94 farms per tractor. In Manitoba there were 18.40 farms per tractor, and in Alberta 10.29 farms per tractor.

The value of farm tractors in operation in western Canada at the close of 1918 was approximately $26,000,000.

LABOR LEGISLATION

LANSING, MICH., June 18—Following is a synopsis of new labor laws and amendments passed during the 1919 session of the Michigan legislature and approved by the governor:

Equal pay for equal service regardless of sex; also to protect female workers in industry by forbidding their employment in an industry where the load is disproportionate to their strength, or in any employment where their morals are in jeopardy or their potential capacity for motherhood will be impaired.

Some of the features of the amendments of the working men's compensation law are the reduction of the waiting period from 2 weeks to 1 week, hospital and medical attendance increased from 3 weeks to 3 months, the minimum pay per week for disability increased from $4 to $7 and the maximum increased from $10 to $14, and disability for which compensation is paid extended from 300 weeks to 500 weeks, making the total that may be collected $7,000 instead of $5,000.

A commission will be created to investigate and report on the industrial conditions affecting labor, including wages, hours of labor, sanitation, safety and health, old age pensions and, in fact, the promotion of the industrial welfare of the state, and to recommend such legislation as will be of benefit to the industrial workers of the state.

Labor associations will be permitted to incorporate for the purpose of building a labor temple and to sell stock to individual members of unions eligible to affiliate with the American Federation of Labor.

Lien laws will be amended to give better protection to mechanics in the collection of wages due.

Joint resolution was passed submitting an amendment to the constitution giving the legislature power to enact laws relative to male labor.

TRADEMARK BUREAU

WASHINGTON, June 20—Plans are under way for the establishment of an International Trademark Registration Bureau at Rio de Janeiro, which will be similar to the Bureau at Havana, and will do for the South American countries what the Havana Bureau is doing for the North American Republics.

The Bureau at Havana enables merchants and manufacturers to deposit their trademarks in the North American Republics and secure protection thereby through one payment and one contract.

AUTO ACCIDENTS IN A. E. F.

PARIS, JUNE 23—That the great majority of automobile accidents are due to carelessness and lack of attention to recognized rules of the road is indicated by American Army statistics compiled during the period of active operations. Ambulances, which are the vehicles most entitled to speed while on the road, have the lowest percentage of accidents, being only 0.5 per cent of the whole. The proportions of accidents for the American Army in France during a period of 12 months are as follows:

Touring cars	67.0 per cent
Trucks	16.5 per cent
Sidecars	14.4 per cent
Unclassified	01.6 per cent
Ambulances	00.5 per cent

The big percentage of accidents among touring cars is attributed almost exclusively to the practice of driving on the horn.

PLAN PETROLEUM INSTITUTE

WASHINGTON, June 21—The establishment of a Petroleum Institute with headquarters here, to investigate the depleting stocks of petroleum and increasing export demands, and the possibilities of accelerating production, has been suggested by refiners at a meeting with Mark L. Requa, who has just resigned as Director General of the Oil Division of the U. S. Fuel Administration.

It was stated that the tremendously increased demands for petroleum, both domestic and export, are problems which will grow in the next few years, and must be solved by scientific production.

Mr. Requa stated that an institute offering means for co-operation of producers with the government, fostering foreign and domestic petroleum trade and promoting the interests of the industry in all its branches, would be lawful and of great importance. No definite steps have yet been taken.

AIRPLANE STATION

NEW YORK, June 23—I. M. Uppercu, president of the Cadillac-Detroit Automobile Co. and sole owner of the Aero Marine Plane & Motors Co., proposes to erect hangars and launching platforms on the New York and New Jersey shores of the Hudson, the former at Fort Washington Point, 177th Street, and the latter opposite 181st Street.

Mr. Uppercu has made proposals to the New York City authorities and to the Palisades Interstate Park Commission, which controls the Jersey shore, for the necessary leases.

In co-operation with other aircraft manufacturers expected to join his project, he contemplates holding demonstrations of flying boats, giving instruction in aviation and generally enlightening the public on air dynamics. Foreign as well as American manufacturers, he added, would be invited to participate.

FINANCE EXPORTERS

WASHINGTON, June 23—An amendment to the Federal Reserve Act that would make available a capital of $100,000,000 to finance export trade has been recommended to Congress by the Federal Reserve Board.

The amendment as recommended would permit any national bank to invest not more than 5 per cent of its capital and surplus in the stock of domestic corporations engaged in foreign trade. Under the present law only national banks having a capital and surplus of $1,000,000 may invest in such stock, though such institutions may use 10 per cent of their capital and surplus for such a purpose.

The proposed change will not only help foreign trade and restore normal conditions to the extent of actual investments by national banks, but the moral effect of the participation of national banks will be stimulating to trade and finance generally.

The change will be temporary, as national banks would be allowed to purchase stock in foreign trade corporations only until Jan. 1, 1921.

UNIFORM TRAILER LEGISLATION

NEW YORK, June 24—The Trailer Manufacturers' Association of America has drafted recommendations covering uniform legislation for the use of trailers, submitting the proposals to the committee in Washington which drew up the uniform traffic bill for introduction into state legislatures.

The draft, pointing to the value of trailer usage in reducing highway freight costs, urges lower license fees for trailers than for trucks, owing to their lesser destructive tractive effect on the roads; repeal of laws prohibiting trailers or more than one trailer to a motor vehicle; changes in state regulations to permit greater gross weights for trucks and semi-trailers than for trailers alone owing to greater distribution of the weight, and to allow greater weights per inch width of tires than in the case of self-propelled vehicles.

Omaha-St. Louis Air Mail Service

WASHINGTON, June 23—Air mail service from Chicago to Omaha and St. Louis is planned to commence in the Fall. It is expected that this service will reduce mail delivery between the Atlantic and Pacific coasts by 16 to 24 hours. Consecutive trips of 325 miles have been made between Cleveland and Chicago without delays, forced landings or engine trouble of any sort, according to reports just made public.

The flights have been made in weather, which a short time ago would have been regarded prohibitive. The planes carry 400 lb. of letter mail daily, and as letters range from 40 to 45 a pound this means that 16,000 letters were transported on each trip. Notwithstanding the weather and the heavy loads, the postal planes, which are the L.W.F.-De Havilands, equipped with Liberty engines, maintain an average speed of 98.5 m.p.h.

Twelve of the L.W.F.-De Havilands are in the Cleveland service, four being stationed at each terminal and four at Bryan.

Some Interesting Time Results

The service shows some interesting time results. Short as this link is in comparison with a transcontinental line, Pacific Coast mail is already advanced 16 hours to Boston and New England points. Pacific Coast mail, routed via airplane link, is delivered in New York in the morning instead of the afternoon.

Westbound, a similar saving is achieved by taking the mail from the 7 a. m. express at Cleveland, transferring it to the postal plane and carrying it on to Chicago at almost double the speed of steam transportation.

From now on, the mail planes will leave Chicago for the East at 2.30 p. m. It was found that 151 great business concerns sent special messenger mail each noon in an effort to catch the two fast mail trains to the Atlantic seaboard. This meant that much of the correspondence had to be completed the night previous. The 2.30 airplane service means that often 8 hours to an entire day is saved and even in the case of the special messenger delivery to the train, from two and a half to three hours are saved.

Operation of the air mail between Cleveland and Chicago has been the means of relieving rail congestion, and one distributing car each way each day has been cut from that division. Distribution of airplane mail is done in the postoffices. This means that $52,000 yearly is saved, while at the same time, rail equipment is released for service elsewhere and mail expedited.

The Department is able to state that experiments are now being carried on looking toward the delivery and taking aboard of mail bags while the airplane is in flight. It is not so many years since it was thought remarkable for a fast steam train to accomplish this feat. It is now regarded as possible for the lightly loaded "ships," those carrying 1000 lb. of mail or less, to come close to the earth and snatch bags from specially prepared apparatus. In the case of the large multi-motored "ships," for which the Department shortly will let bids, no attempt will be made to come near the ground, but a scheme is proposed for dropping mail and possibly taking on from the roofs of buildings. If this proves practicable it will be possible on the New York-Washington route to make non-stop runs, serving both Philadelphia and Baltimore, and eliminating 15 min. stops at each place.

Another interesting development which it is now possible to announce is the construction of fireproof walls between the mail compartment and the engine and the compartment and the gas tank. A fireproof, airtight bag exactly the size of the compartment will be installed and within this a second fireproof bag containing the mail pouch. In this manner, tests have demonstrated danger of destruction by fire is practically eliminated.

BRAZIL AVIATION PLANS

WASHINGTON, June 21—The government of Brazil has issued a decree giving permission to two citizens of that country to use airships for the transportation of passengers and merchandise between the principal cities of Brazil. The concession is not exclusive and the service must be inaugurated within two years. The concession allows the transportation of passengers and merchandise with the understanding that all mail is to be carried gratuitously, it being understood, however, that no mail is to be transported unless it has been duly stamped by the National Post Office.

The number of voyages and passenger and freight rates will be subject to control of the Brazilian government. The regular service of transporting passengers and merchandise cannot be initiated without prior license from the government, which will regulate all conditions. The owners of the airships obligate themselves to admit apprentices of the National Aviation School on their airships and in their shops. In case of war the government has the privilege of taking over the service.

OLYMPIAN SELLS WAR MATERIAL

PONTIAC, MICH., June 24—War material which was to have been used in the manufacture of aerial drop bombs by the Olympian Motor Co. will be sold at auction June 27. The material consists of sheet steel, steel stampings, steel tubing, brass rods, steel rivets, wire brazing brass, welding iron wire, wire solder, coated nails, wrought staples, cotter pins and hemp rope. The sale will be for cash to the highest bidder. The material has been divided into separate lots upon which individual bids may be made. It will be conducted under the auspices of the United States Navy. Bids will be open at 10 a. m. More than 3000 aerial drop bombs were made by the Olympian company.

SHIPMENTS TO DENMARK

WASHINGTON, June 23.—Shipments recently gone forward to Denmark should have been consigned to actual consignees instead of the Merchants' Guild of Copenhagen or to the Danish Chamber of Commerce, as was done, according to a report of the War Trade Board.

In view of the fact that consignment to these associations causes inconvenience to the associations and delay in releasing the goods to the actual consignees, instructions have been issued to the Collector of Customs to permit shipments to Denmark only when the commodities are consigned directly to the actual consignees.

The attention of exporters is further directed to the War Trade Ruling 784, issued June 18, 1919, giving the details of Special Export License RAC-81, permitting the shipment of nonconserved commodities to Denmark.

GERMAN SCIENTIFIC BOOKS

WASHINGTON, June 21—The War Trade Board will consider applications for licenses to import into the United States from Germany or elsewhere, scientific books and journals which were printed in Germany. Licenses covering such importations will not, however, be issued until the importer in the United States has made effective arrangements to make the purchase price of such books or journals available for the purchase of foodstuffs for Germany.

TIRE FACTORY IN MEXICO

WASHINGTON, June 21—A tire company has been organized under the name of the Fomenot de Comercia Internacional, S. A. (International Commerce Exchange), in Mexico City, to manufacture rubber tires and tubes. It is a private enterprise according to Vice Consul McEnelly, with an investment of $350,000, employing 110 men at present and with capacity for 350. The plant is modern and operated by electricity and oil for fuel. It is turning out 25 tires and inner tubes daily.

PANHARD FOREIGN BUSINESS

GRAND HAVEN, MICH., June 24—The Panhard Motors Co. is pushing its foreign business and has closed contracts in England, India, Sweden, Finland, Denmark, Brazil, New Zealand, Japan, and China.

SINGLE STATE TAX FAVORED

WASHINGTON, June 20—A petition, favoring the bill introduced by Congressman Fuller, providing that anyone found qualified to operate an automobile in one state will not be obliged to make additional registration or take out additional licenses or pay additional taxes when traveling on pleasure or business in other states, was filed with Congress this week by the National Automobile Dealers' Association.

The bill provides that the certificate of local officers of a state should be accepted in all states of the country as competent and sufficient evidence that the owner has complied with the laws and regulations of his residential state. It was referred to the Committee on Interstate and Foreign Commerce as it is intended to regulate the interstate use of automobiles and all "self-propelled" vehicles using public highways for interstate commerce.

AIRPLANES FOR SALE

DETROIT, June 24—The Thompson Auto Co. has purchased 20 Curtiss airplanes from the United Aircraft Corp., New York, and is introducing them with a canvas sign announcing "Airplanes for Immediate Delivery."

EXPORT CO. DIRECTORATE

NEW YORK, June 24—Gaston, Williams & Wigmore, Inc., exporters of automobiles and other commodities, added the name of John W. Prentiss to its directorate at the recent annual meeting. Other directors are Charles H. Sabin, George A. Gaston, George M. Dahl, Harry Payne Whitney, Charles A. Corliss and James J. Phelan. Mr. Sabin, president of the Guaranty Trust Co., is chairman of the board.

The net income for the year ending April 30, was $1,262,401, and dividends aggregated $1,050,000.

NEW MACHINE SHOP

BOUND BROOK, N. J., June 23—The Bound Brook Oil-less Bearing Co. is having a 2-story office building and machine shop erected, 100 by 180 ft., of concrete and steel. By the addition of this building, the entire factory will be located at one point.

NEW TREATY WITH PANAMA

WASHINGTON, June 20—A commercial treaty between the United States and Panama, ratified to-day by the Senate, facilitates the development of commerce and the work of traveling salesmen.

Manufacturers, merchants or salesmen can operate as commercial travelers in either country if a resident of one, upon the payment of a single fee for a license which will be valid in all of the territorial jurisdiction of the country. To secure a license the applicant must file a certificate secured from the country of residence of the employer declaring him to be a commercial traveler. Samples may be sold without securing a special importer license. Samples without commercial value will be admitted free of duty, and those having a commercial value will be admitted under bond for lawful duties if not withdrawn within 6 months after entrance.

All customs formalities are to be simplified to avoid delay in the dispatch of samples. No license will be required of anyone traveling to study trade even though they initiate commercial relations, provided they make no sales.

AMERICAN BRANCHES IN MEXICO

WASHINGTON, June 23—Reports from the Vice-Consul at Mexico City indicate the need for establishing branches of American automobile manufacturers in Mexico. Large numbers of sales have been reported, but complaints are made by buyers that poor service is tending to ruin the reputations of many high-class passenger cars.

The accompanying illustration is of a photograph taken nineteen years ago, in front of Rhode Island's first "Horseless Carriage" factory in Providence, and operated by Hughes & Atkin. Now known as the Wm. Hughes Company, the oldest exclusive Reo car dealer in New England, having taken on the Reo line some thirteen or fourteen years ago. The "Horseless Carriage" as shown here is one of the eighteen built by Mr. Hughes in 1899 and 1900, the first in New England, for which he made nearly all parts by hand. As late as thirteen months ago one of these cars was seen operating on the highways of Rhode Island

In Keeping With Good Cars

Keen competition demands that every item you put into your cars be the best of its kind.

RUSCO BRAKE LINING, CLUTCH FACING,

and other Rusco Automotive Products measure up to this high standard.

For 88 years the name "Rusco" has stood for all that is best in webbing products. Rusco quality is pre-eminent in

Brake Lining, Clutch Facings, Anti-Squeak Webbings, Woven Auto Top Straps, Tire Straps, Fan Belts, Hood and Radiator Lacings, etc.

Rusco Brake Lining is guaranteed for one year

Write for our interesting, instructive book on Rusco Automotive Products. It contains the complete story of Rusco Quality.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE
THE CLASS JOURNAL COMPANY
231—241 W. 39th STREET NEW YORK CITY

CONTENTS

VOL. XL NEW YORK, June 26, 1919 No. 26

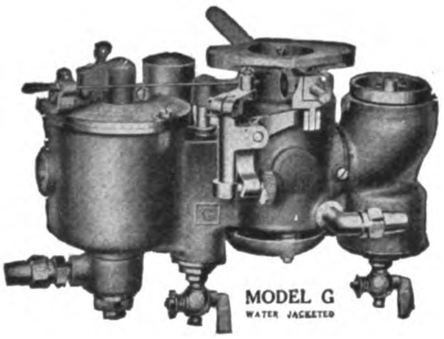
Gradually the industrial effort in this and other countries is working round to the peace requirements and adjusting itself to the after war period of industry. The demand for raw materials, metals, etc., is beginning to move and there are signs of an export revival in these lines. Construction is being started in housing and some of the larger building problems. In the automotive field the market is still ahead of the production and the outlook for progress in this field is excellent.

It is probable that the economic changes brought about by the war and realized as of great importance in this post war period will demand keener attention in merchandising and advertising and in all problems having to do with distribution of goods. As in selling so in advertising, the most profitable line of development is the shortest line of attack between the manufacturer and the most important buyers and users of the product.

"AUTOMOTIVE INDUSTRIES" offers a direct line between those who have products to sell to the manufacturer of automotive equipment and the manufacturer who must use them.

RAYFIELD CARBURETORS

Rayfield Superiority Acknowledged by Leading Motor Car Manufacturers



Model G—Water Jacketed

Rayfield results are obtained by many years' experience, not by chance.

Backed by years of acknowledged superiority Rayfield carburetors are now standard on many of America's finest cars.

The good judgment of these manufacturers is reflected in the keen enjoyment of the motorist in the knowledge that his motor will respond eagerly under all conditions. In addition to this great flexibility Rayfield carburetors will save from 20% to 50% in gasoline consumption.

More than a thousand dealers operating under the Rayfield service station sign found that the reputation of Rayfield efficiency is bringing them a constantly increasing profit from satisfied users.

Specified for Efficiency

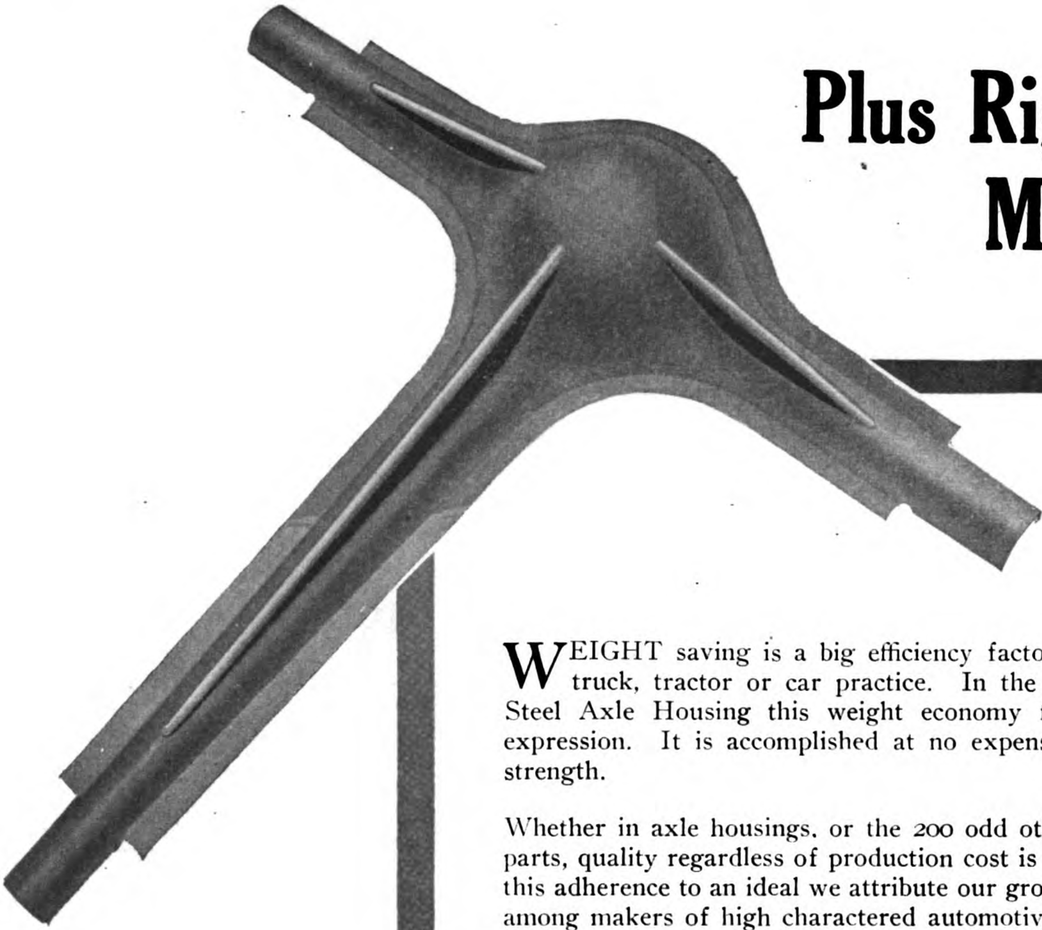
2100 Rockwell Avenue CHICAGO, ILLINOIS

Plus Rigidity Minus Weight



Axle Housings that combine the qualities of Rigidity, Strength and Light Weight have been made possible only through Bossert Facilities.

WEIGHT saving is a big efficiency factor to consider, in truck, tractor or car practice. In the Bossert Pressed Steel Axle Housing this weight economy finds its highest expression. It is accomplished at no expense of rigidity or strength.

Whether in axle housings, or the 200 odd other pressed steel parts, quality regardless of production cost is maintained. To this adherence to an ideal we attribute our growth and prestige among makers of high charactered automotive products.

From small parts to axle housings this high standard is maintained in both material buying and production.

This, the largest plant of its kind in the world, is the best equipped. Its factory personnel is the most highly specialized. Its engineering departments the most capable.

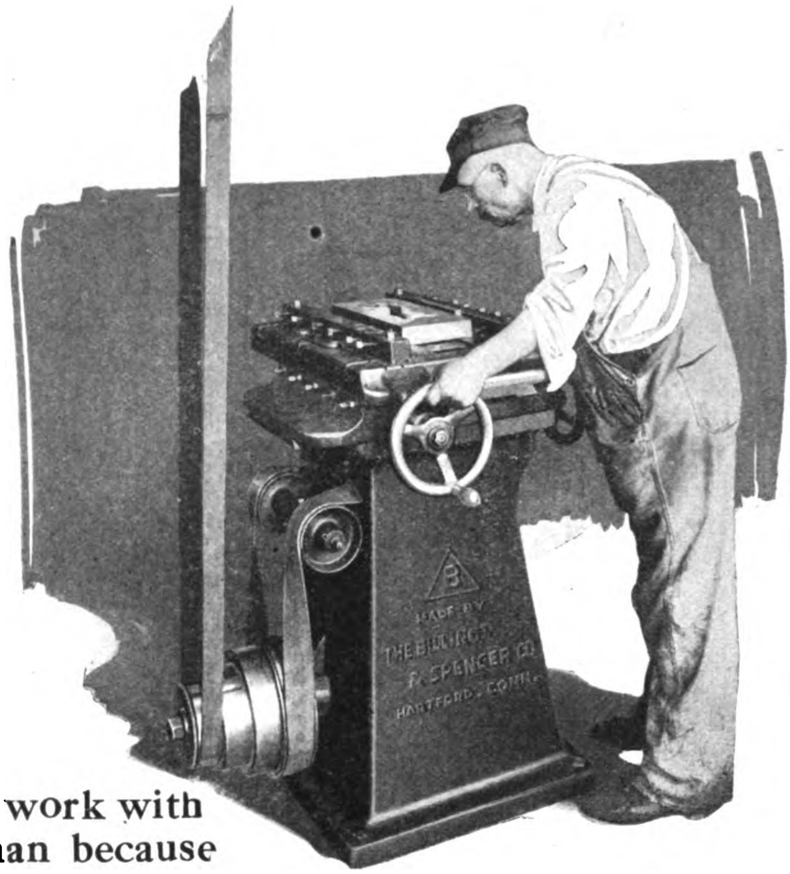
It follows, then, that "The Bossert Way" offers quality products at moderately consistent prices, and that its facilities for quick work and delivery leave nothing to be desired.

Our engineers will show you where pressed steel parts will replace drop forgings, steel and malleable iron.

THE BOSSERT CORPORATION
Utica New York

BOSSERT

With Infinite Care!



MAN and machine, they work with infinite care—The man because he has been trained for a lifetime in tasks requiring the utmost exactness—The machine because it is made by Billings & Spencer for their own use, and for the use of other drop forgers of reputation.

This trimmer miller of improved design quickly and cleanly mills the irregular outlines of trimming press dies, and at the same time their necessary draft or clearance. It also cuts the flash from drop forgings, and mills cutting dies of all descriptions for press work.

You will be particularly interested in the oiling system for the vertical spindle bearings and the method of chip disposal so as not to interfere with the moving parts of the machine.

Full details upon request.

HOFFMAN PROCESS

Indications and record of the temperature at which Hoover balls are heat treated insures fine grained structure as shown above. This, of course, results in the production of a ball of maximum durability.

Failure to make positive that control as mentioned above may result in the coarse grained and weak structure as illustrated. A ball of such structure is apt to fail even under normal strains. Avoiding defects of this nature is one of the functions of the Hoover Research and Control Laboratories.

Hoover Testing Methods Remove Hoover Balls from the Domain of Chance

There is never an opportunity for a doubt concerning the finished quality of Hoover Steel Balls.

That is because "Research" establishes Hoover specifications—and "Control" sees that they are carried out.

By "Research" we mean the careful tests and investigations which are made in the Hoover laboratory to establish definite standards for the steel, the oils and greases, the grinding and polishing wheels, the abrasives and other materials which are used in the manufacture of Hoover Steel Balls.

By "Control" we mean the daily routine tests also made in the Hoover Laboratories—to see that there isn't the slightest deviation, either in materials or manufacturing methods, from the specifications which have been been so rigidly laid out.

As the backbone of the great Hoover plant, the Hoover Research and Control Laboratories labor unceasingly to maintain the well known superiority of Hoover Steel Balls. The result is a product as perfect as it is possible to manufacture.

As the largest steel ball plant in the United States we are prepared to meet practically any shipping specification which may be submitted to us.

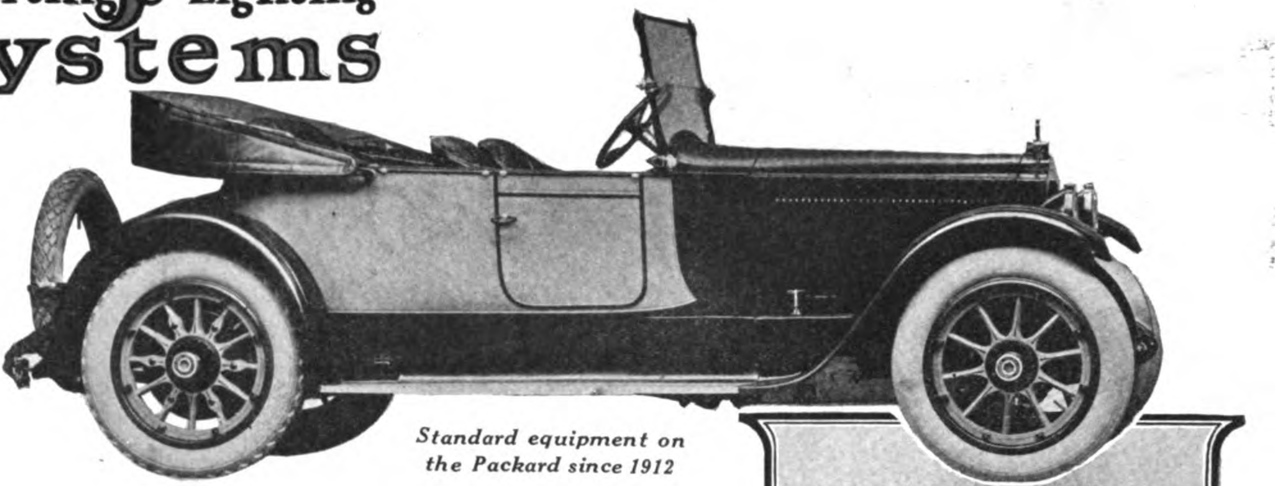
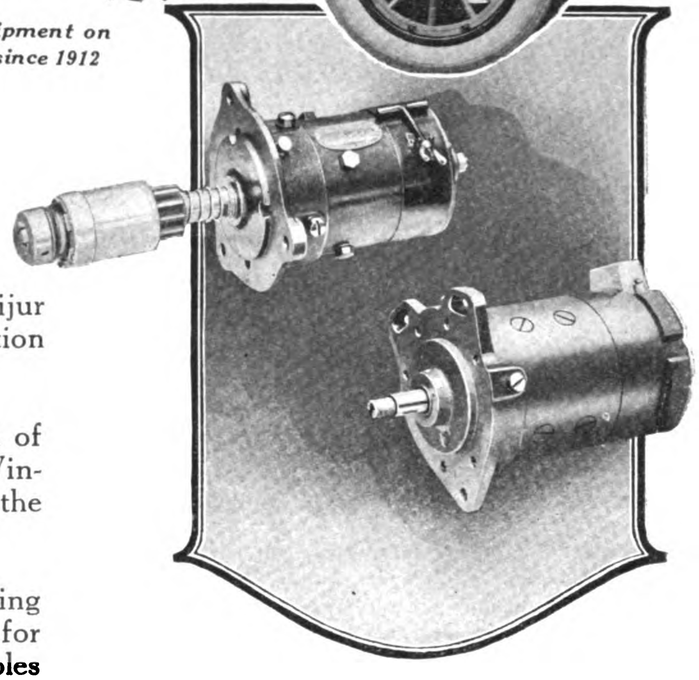
Bijur Starting & Lighting Systems



Standard equipment on the Packard since 1912



On Fine Cars the Bijur System Is an Assurance of Dependability

THE quality of the cars which use the Bijur Starting and Lighting System is an indication of merit.

Beginning with the Packard in 1912, adoption of the Bijur System has extended to the Marmon, Winton, Apperson, Jordan, King, Roamer and the Peugeot of France.

Besides meeting the requirements for the leading passenger cars the Bijur System has been adopted for use on motor trucks, air and sea planes, dirigibles and tanks.

The Starting of DePalma's 150 mile an hour Packard was not too heavy, the transatlantic flight of the NC Planes was not too far, and the design of the Bijur Starters is such that no application can be too small for the Bijur System to meet effectively.

Bijur Engineers are prepared to discuss plans and suggest designs for the incorporation of the Standard Bijur System to any form of automotive starting and lighting duty.

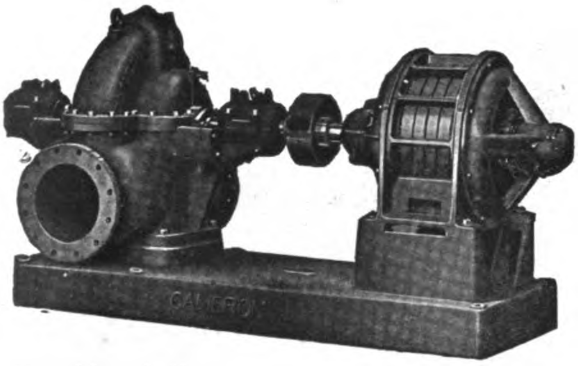
CAMERON PUMPS



Motor-driven double-suction volute pump.

On Hospital Duty

Here is what the chief engineer thinks of the Cameron—

Hospital St. Boniface,
St. Boniface, Man.,
March 4, 1919.

Canadian Ingersoll-Rand Co.,
Montreal, Quebec.

Dear Sirs—Regarding two Cameron Class DV volute type pumps furnished by your people to the hospital, I am pleased to say they are giving good satisfaction. They have been pumping 250 gals. P. M. against a head of 160' for as long as 11 months without a shutdown. They are still running without noise or repairs of any kind. No. 1 is direct connected to steam turbine and running 2500 R. P. M. No. 2 is a duplicate of No. 1, except the latter is electric-motor driven. I can recommend the Cameron Pump to any firm wishing a real pump to do real work, as we forget to notice our pumps unless some person wishes to see them running.

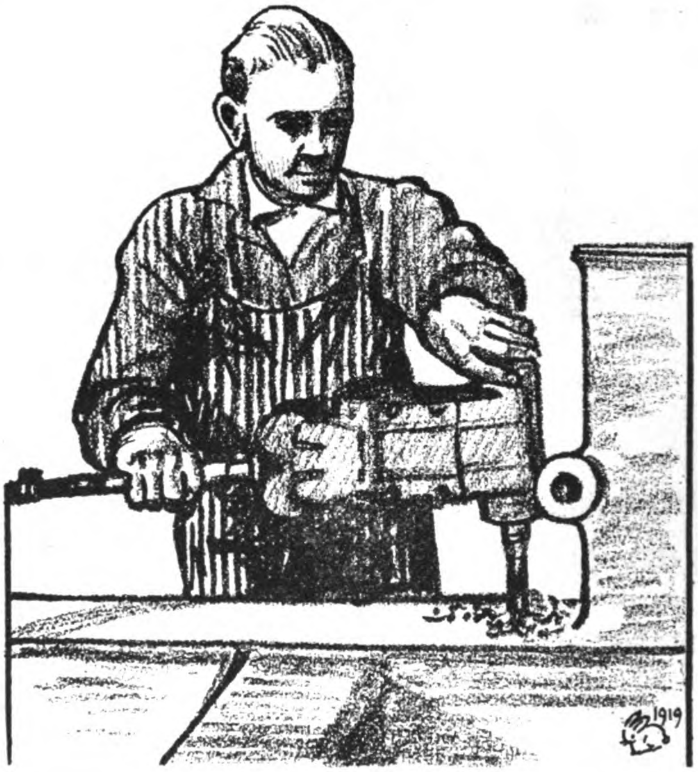
Yours sincerely,
GEO. K. BEERS,
Chief Engineer.

The Cameron line is complete and contains pumps for nearly all uses and sizes to suit every requirement. Send for Bulletins 7150, 7204.

49-DV

"LITTLE DAVID"

Close Quarter Drill



The position of the spindle in a close-quarter drill brings up special problems in the design of the tool. In the "Little David" these have been solved in a most satisfactory way.

The spindle is operated by ratchets on three rocking levers, which are connected direct to the pistons. The levers also operate the crankshaft, the only function of which is to control the single rotary valve and the pistons on the return stroke.

The "Little David" is easier and cheaper to operate and repair and contains less than one half the number of parts of any other close quarter drill on the market.

SHELDON AXLES ARE NOW TO BE ADVERTISED in a much more vigorous manner than ever before, through a campaign which will reach practically every source of demand for high grade motor trucks. Repeated use of large space in the magazines of widest circulation and greatest influence will feature the campaign.

PERIODICALS OF NATIONAL CIRCULATION are to be employed—among them *The Saturday Evening Post* and the leading business and trade publications.

IN LANGUAGE FREE from mystifying technical phraseology, the story of Sheldon's great achievement in axle construction will be unfolded before the layman. A straight appeal that puts it squarely up to his sense of values, performance and economy will show *the man you want to reach* why the truck he buys should have a Sheldon Worm Drive Axle.

FOR YEARS THE NAME SHELDON, among technically trained men, has been a symbol of supreme quality in axle design. And Sheldon copy will show clearly why Sheldon has won the unqualified endorsement of engineering opinion the world over.

See next two pages for reproduction of Saturday Evening Post advertisement for June 28th

1901 Double Page S. E. P. ★ ★

Sheldon

FOR MOTOR

Automatic Adjustment

Expansion due to heat is compensated automatically in Sheldon Worm Gear Axles.

The Sheldon thrust bearing is a ball bearing—the only type of bearing that will take the thrust of the worm in both directions. The Sheldon front bearing is free to move as the worm expands, and thus adjusts itself to expansion and wear.

Sheldon Axles are Self-Adjusting

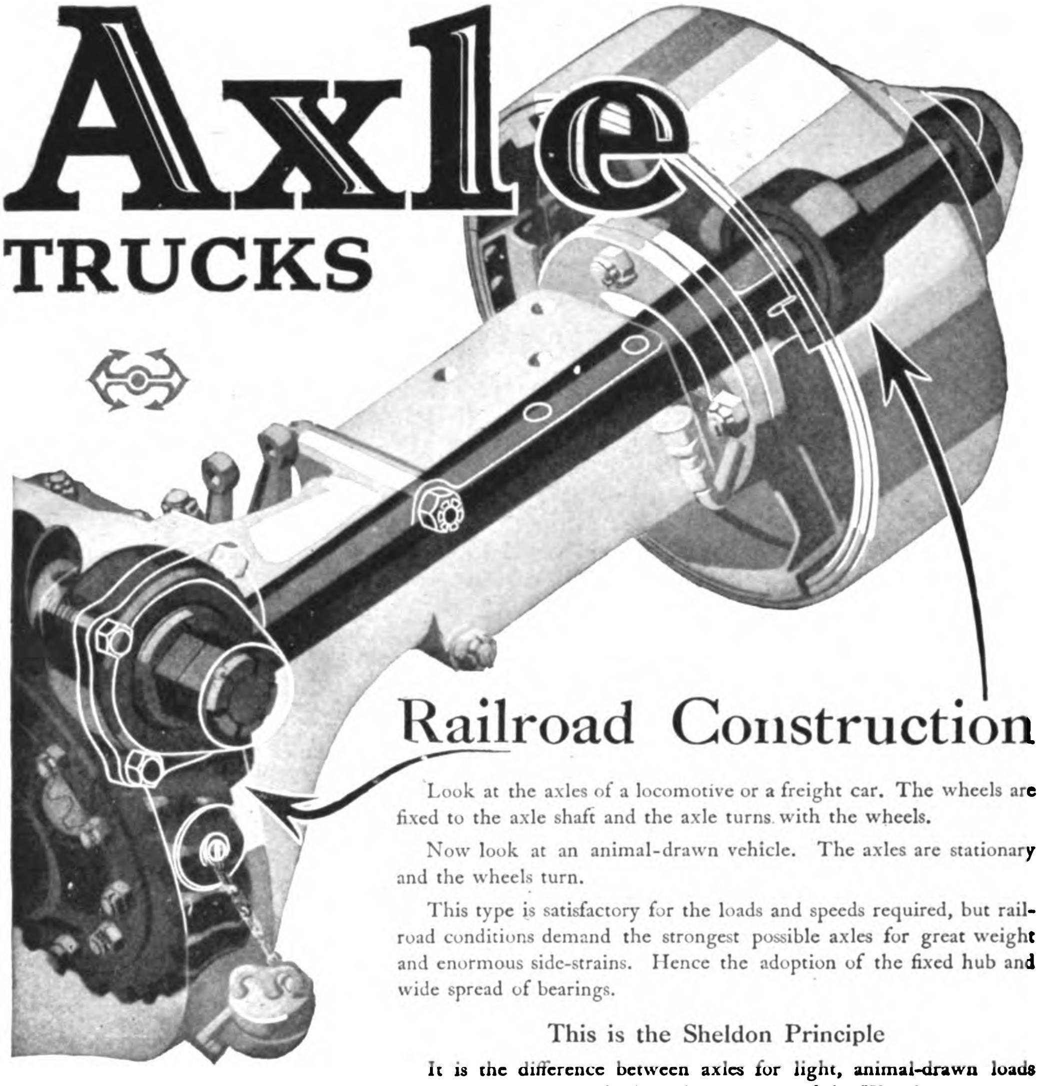
No external adjustment is necessary—therefore it is not provided.

In the Sheldon thrust bearing adjustment is automatic, which takes care of the expansion in the worm and prevents tight bearings and loss of power.

In addition to this feature, ball thrust bearings take all combinations of radial and thrust load directly through the center of the balls, so that wedging is impossible and friction is reduced to the minimum.

THIS is the first of a series of dominating advertisements which will appear in leading publications of national circulation.

Axle
TRUCKS



Railroad Construction

Look at the axles of a locomotive or a freight car. The wheels are fixed to the axle shaft and the axle turns with the wheels.

Now look at an animal-drawn vehicle. The axles are stationary and the wheels turn.

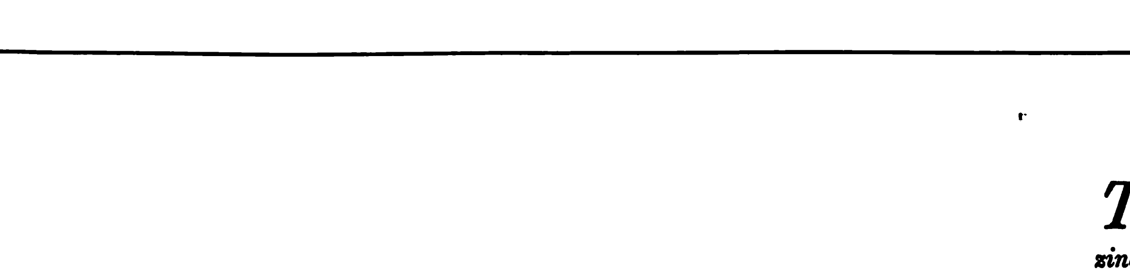
This type is satisfactory for the loads and speeds required, but railroad conditions demand the strongest possible axles for great weight and enormous side-strains. Hence the adoption of the fixed hub and wide spread of bearings.

This is the Sheldon Principle

It is the difference between axles for light, animal-drawn loads and Axles that Carry the Freight Tonnage of the World.

Send for catalogue explaining the Sheldon points of superiority

SHELDON AXLE & SPRING COMPANY, Wilkesbarre, Pa.



THE Saturday Evening Post and other magazines will carry the message of SHELDON quality to many millions of readers this year.

SLOCUM-AVRAM-SLOCUM MANAGEMENT

A Service That Eliminates Labor Difficulties

Did you ever figure out what labor turnover costs you in a year?

The problem of getting and keeping skilled help is but one of the many labor difficulties that beset both the old established as well as the new manufacturer.

The fact that the "manufacturing aid" service offered by the Slocum, Avram & Slocum Laboratories eliminates labor difficulties has very often been the dominant reason for manufacturers having all or part of their product manufactured in the plant shown below.

Other features of this service are outlined at the right.

Your communication will receive our prompt and efficient attention.

Real Manufacturing Aid

If yours is a problem of greater production—the development of a new part or the redesigning of an old one—new tools, jigs, fixtures or special machines—or if you are looking for a complete and efficient organization to take over the manufacture of certain parts send your problems to Slocum, Avram & Slocum Laboratories.

Asbestos Rock

Sorting Fibre

Have your jobber check us up on this

THE uncertain supply of special grades of asbestos fibre gives the phrase "From Mine to Brake" a deeper significance for Jobber and Dealer than ordinarily.

The ability of Johns-Manville to continuously supply you with a uniformly high-grade brake-lining—Non-Burn—was never so clearly shown as today, when all markets are uncertain.

The fact that we do mine, spin and weave this lining from beginning to end, in a sense underwrites and makes valid our sales policy, which has for years assured the trade of not only a good lining, but the best lining, honestly merchandised and always obtainable.

There must never be any doubt as to the quality of this lining, or the spirit back of its sale. Ask your jobber about it.

P.S.—All indications from everywhere point to a straight-through-the-summer lining business. Your customers know Non-Burn because they know Johns-Manville. You can tell them that we stand back of it. They know what that means.

Auto-Lite

Starting, Lighting & Ignition

The Big Little Generator

ONLY 4½ inches in diameter, this Auto-Lite Round Type Generator is one of the smallest and lightest made. Yet it has a marvelously large output capacity.

Frame and four poles are of rolled steel. It is self regulating through the Third Brush System, which means no sticking, corrosion or variation in its adjustments.

It begins to charge into the battery at the low speeds used in city driving and automatically decreases the charge at higher speeds, thus preventing depreciation of the battery.

A generator that is wonderfully compact and trustworthy.

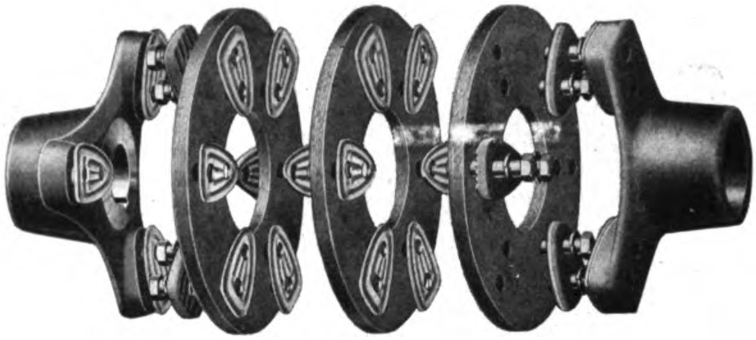
FLEXITE

Trade Mark Registered

HEAVY DUTY UNIVERSAL JOINTS



PARTS OF A FLEXITE HEAVY DUTY UNIVERSAL JOINT

THE FLEXITE DISC

The Disc Carries the Load

Flexite discs are correct mechanically, because both in design and production they follow sound engineering practice.

Each careful step in their manufacture has an ultimate purpose in the proper functioning of the finished product.

This is why Flexite Discs secure strength without stiffness and flexibility without weakness.

Each Flexite Disc acts as a series of flexible links in transmitting the power.

The load on the disc is evenly distributed over its entire width.

The Flexite Discs carry the load without transmitting the shocks of sudden starting and stopping.

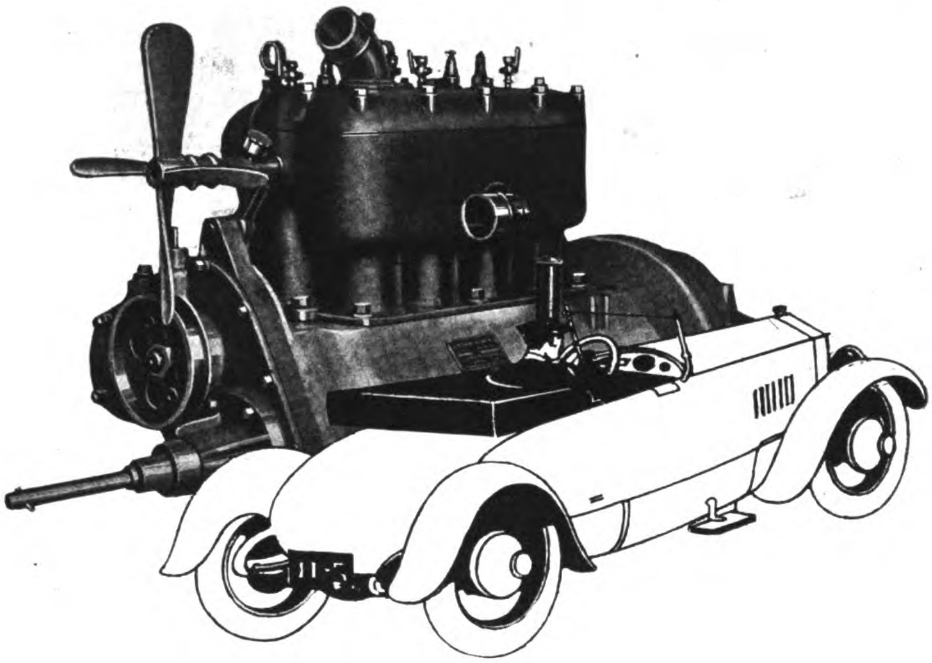
LYCOMING

MOTORS



You Sell Your Car on a Promise of Performance

ON its ability to live up to that promise, depends its reputation with the motorists and dealers to whom you must look for future sales.

The essential factor in the performance of any car is its engine. Before anything else you must insure its power producing qualities and its capacity to stand up under service.

If your car is equipped with a Lycoming Motor you are certain of these fundamentals. You know that its reputation for power and reliability is safe. You know you have laid the foundation for its lasting popularity.

A study of the blueprints and specifications of the Lycoming Motor will convince you of this. Write for them today and find out for yourself what the Lycoming Motor offers you in the way of simple, efficient design, quality materials and high grade workmanship.

Model K, 4 cylinder, L-head, 3 point suspension. Bore, 3½", by 5" stroke. S.A.E. h.p. 19.6; 30 B.H.P. at 1450 R.P.M.

THE MOTOR FOR THE DISCRIMINATING CAR BUILDER

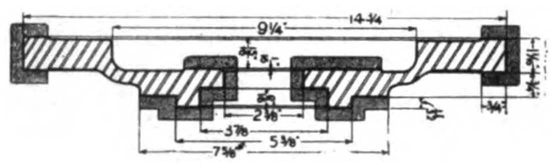
BULLARD

Released 60 Men and a Roomful of Machines

THOUSAND after thousand of the flywheel shown here have been produced on the BULLARD MULT-AU-MATIC in an average time of 2 min. and 15 sec. each. Best previous time, in machines selected and tooled to obtain highest efficiency, 15 min. each. And the work of the Mult-Au-Matic was of a higher and more uniform quality. It is an evidence of the dependableness of the Mult-Au-Matic and its capacity for maintaining production at a high rate.

On another job the Mult-Au-Matic is producing in one hour 80 pieces. Best former record 20 pieces in one hour.

Still another Mult-Au-Matic job shows an increase of ten to one over former methods.



Motor Fly Wheel

Cast Iron

Total Time, Two Chuckings,	2 Min. 15 Sec.
First Chucking..............	1 Min. 22 Sec.
Second Chucking............	0 Min. 53 Sec.

BULLARD

MULT-AU-MATIC

is six machines in one, and requires but one operator. It is a saver of money, men and machines. Less investment is required, less floor space, less tool expense, lower maintenance charges, and but one man is required to obtain its maximum production.

The Mult-Au-Matic includes in its scope all classes of castings, forgings and bar stock cut to lengths, coming within its capacity and requiring boring, turning, facing, etc., operations either singly or in combination.

If you have work for this machine, write us for an estimate. Let us show you that your cost can be reduced, time saved, and overhead cut down.

KISSEL TRUCKS

"Uninterrupted Transportation"

Solving the Nations Readjustment Problems

THERE is no question as to the productive ability of America—that has been proven.

The real problem that confronts the American business man is to keep up an endless flow of supplies, materials, goods, etc., to port of shipment.

In other words, there must not be the slightest uncertainty of delivery on schedule time, of necessary living supplies and necessities which not only Europe is looking to us to provide, but on which our Nation's commercial and social life depends.

No truck purchaser can afford to purchase motor trucks backed up by doubtful manufacturing facilities. He cannot afford to trust his transportation problems to trucks that have not demonstrated their mechanical superiority. It is plain, good business judgment to place your choice of trucks in trucks that—value for value—quality for quality—measure second to none; trucks that are backed up by intensive as well as extensive manufacturing and service facilities—trucks that are the result of studying the peculiarities that characterize the delivery and hauling problems of your own business.

The Kissel Truck owners of today made their final choice because investigations proved that they were built on correct mechanical principles, insuring satisfactory and continuous service and performance.

Take the nationally known corporations and industries that employ fleets of Kissel Trucks. Their purchasing experts made no half-hearted investigations; they knew that the rise or fall of their business institutions depended on the successful solution of their transportation problems. Consequently their investigations were sweeping in every detail—they were investigations that only transportation experts know how to make.

Their experience had taught them that a truck in order to endure and survive the grill of exceptional demands and conditions must be built unusually strong. They found that this was the dominating thought in every step of Kissel truck construction, from the selection of material, the testing of the steel and other components, the liberal dimensions and highest grade construction of the frame, axles, springs, brakes, etc.—up to the famous Kissel-built power-plant specially designed for motor truck requirements.

And when it came to a final checking up, the result which caused their decision was that a Kissel Truck chassis was a scientific achievement, strongly built and perfectly balanced.

The unusual transportation demands now being made on every manufacturer and industry, necessitates every truck purchaser taking the chance out of truck buying—the uncertainty out of truck performance—the risk out of truck investing. The great importance of your transportation equipment keeping pace with your production facilities is too vital to trust to any truck but the one that fits your problems.

Kissel long ago found that no two transportation problems are alike. Each requires individual study, intelligent analysis. Your nearest Kissel dealer is prepared to show you how the perfection to which Kissel Trucks have been brought is your protection—protection in your investment—in your haulage delivery and shipping department—in your present and future volume of business.

Every Kissel Truck represents eleven years of truck experience and experiments—investigations and tests—with never a failure—and the first Kissel Truck still in active service.

This calls for a truck with unlimited hill-climbing power, speed ability on good roads, wear-durability on bad roads, emergency capacity, rapidity of loading and unloading, ease of operating and driving in traffic zones at low upkeep. These truck requisites that are built into Kissel Trucks are absolutely necessary to solve the unusual readjustment transportation problems which every manufacturer and industry has been called upon to face.

Purchase motor trucks as you purchase any other part of your equipment. You will find it's a good business practice from every standpoint.

Kissel Truck dealers are in every principal city. Literature on request.

Kissel Motor Car Co.
Hartford, Wis., U.S.A.

To Tractor Manufacturers

Reconstruction has given birth to countless tractor problems.

Sources of raw materials are uncertain — trade channels are blocked — local conditions in your new territories unknown —problems of manufacturing and equipment are many.

Appreciating the need of the tractor industry for an absolutely reliable source of supply for bolts and nuts, we are now in a position to give special attention to the tractor manufacturer.

A Tractor Is Often Operated Far From the "Base of Supplies"

UNLIKE the driver of the touring car or limousine the operator of a tractor cannot run his machine around the corner to a garage. Repairs must often be made on the field and the successful tractor must be as near "repair proof" as it is possible to make it.

Bolts, nuts and rivets form a super-important part of tractor assembly if a "repair proof" condition is to be attained. Protect the tractors you build from bolt, nut and rivet breaking and stripping by using the brand that has won nation wide renown.

WANTED—A MAN

THE President of a well-known nationally advertised motor truck concern desires to be relieved of some of the important details of administering the affairs of the organization. He requires the services of

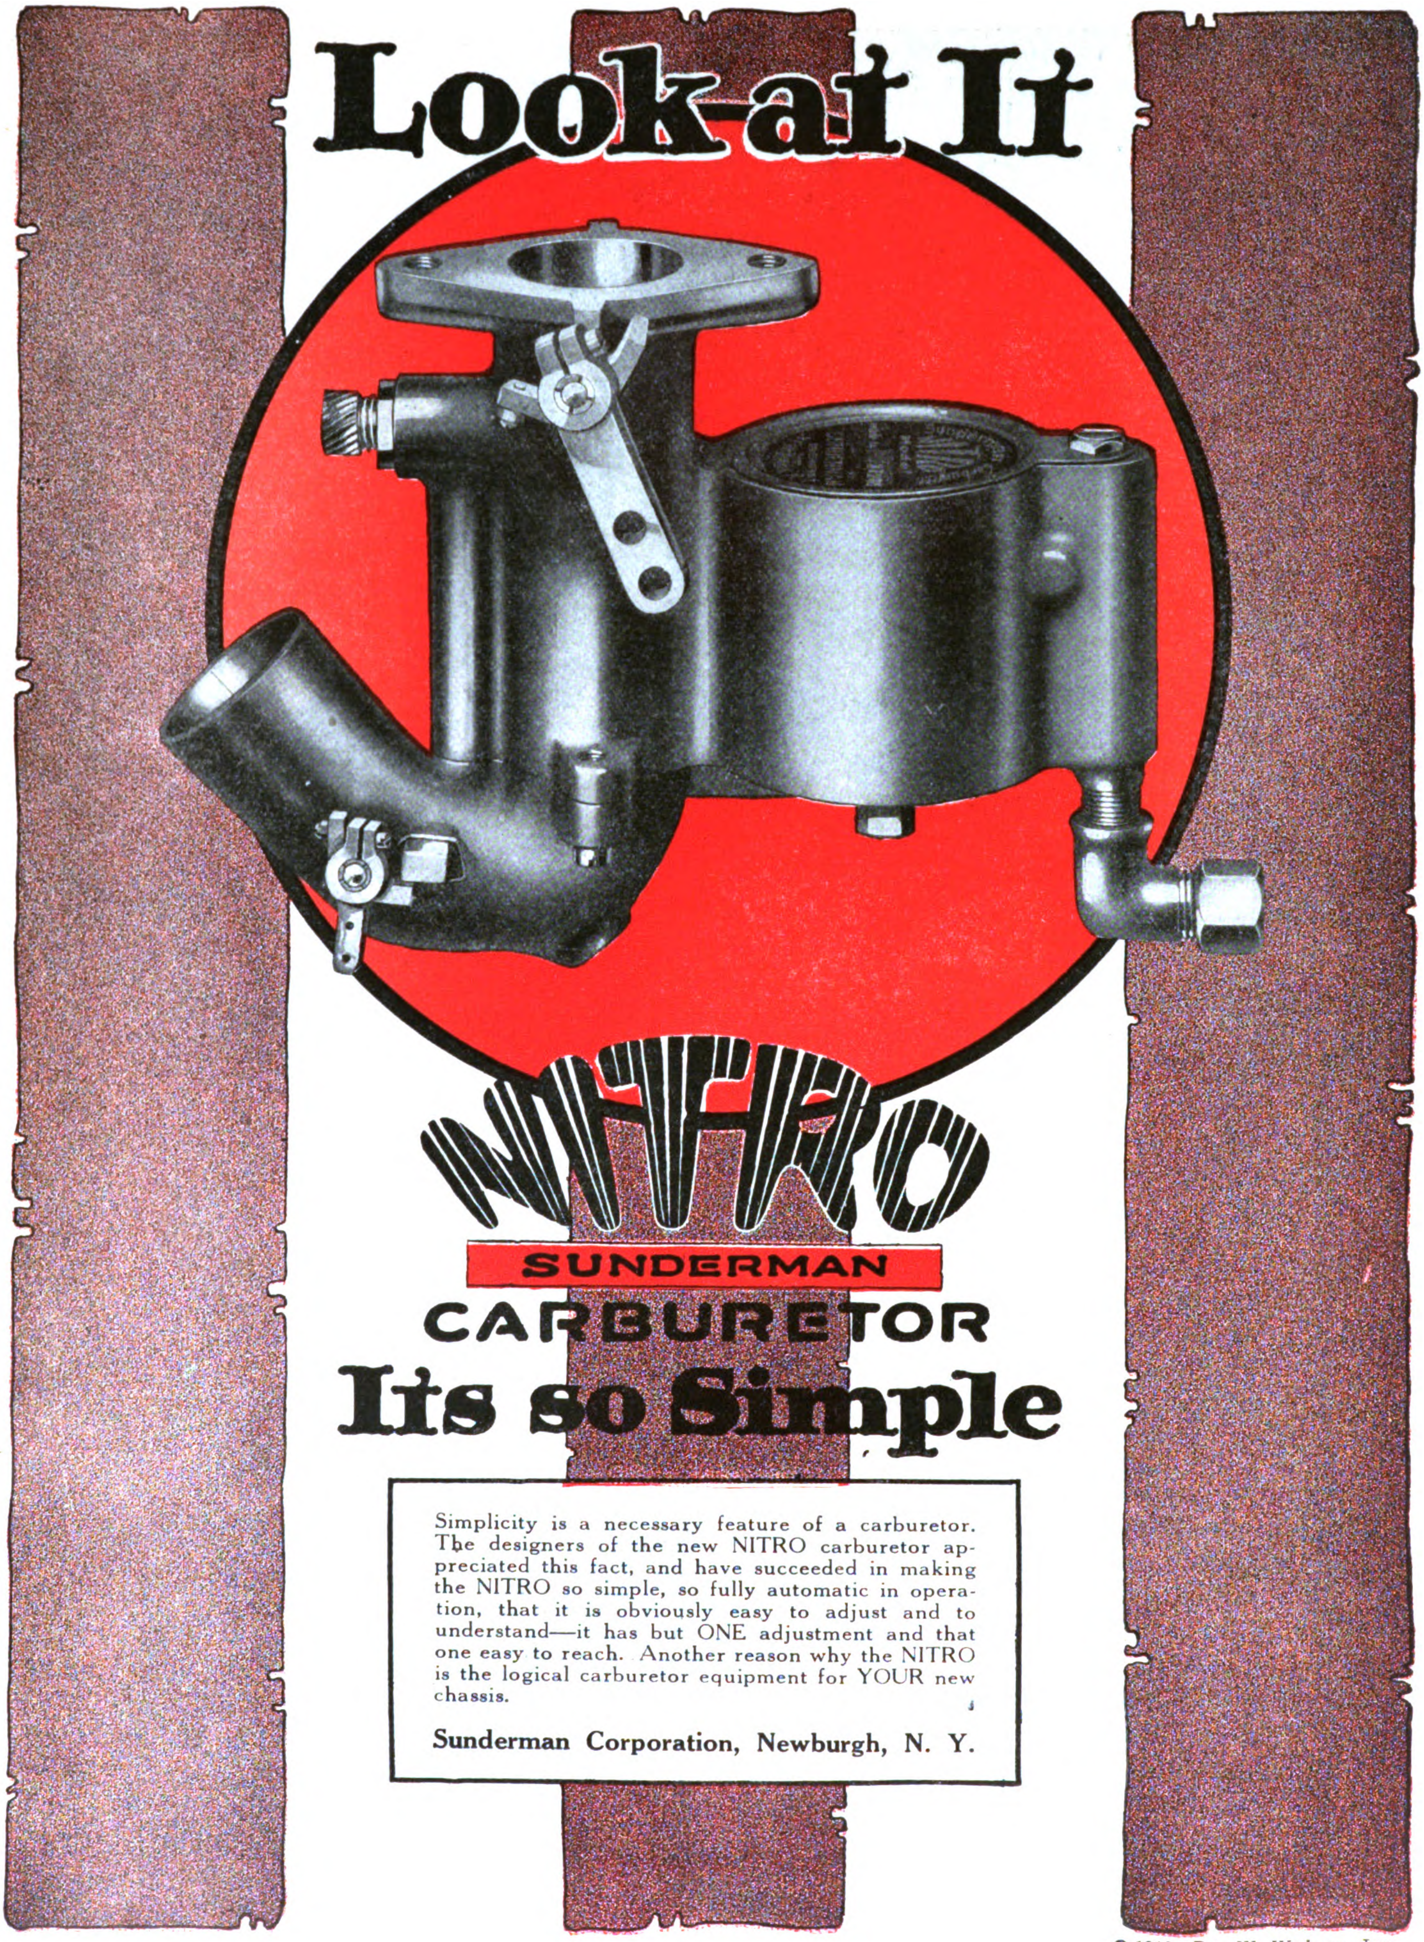
A General Manager

A man with a record of success in the truck field—a man who thoroughly understands the merchandising of a high grade truck—who knows the retail selling angle—the distribution problems—the manufacturers' problem and can make good. Of course, he must have energy, initiative and progressiveness enough to shoulder responsibility and discharge it with promptness and efficiency. To such a man an unusual opportunity is offered and a salary commensurate with the size of the job will be forthcoming.

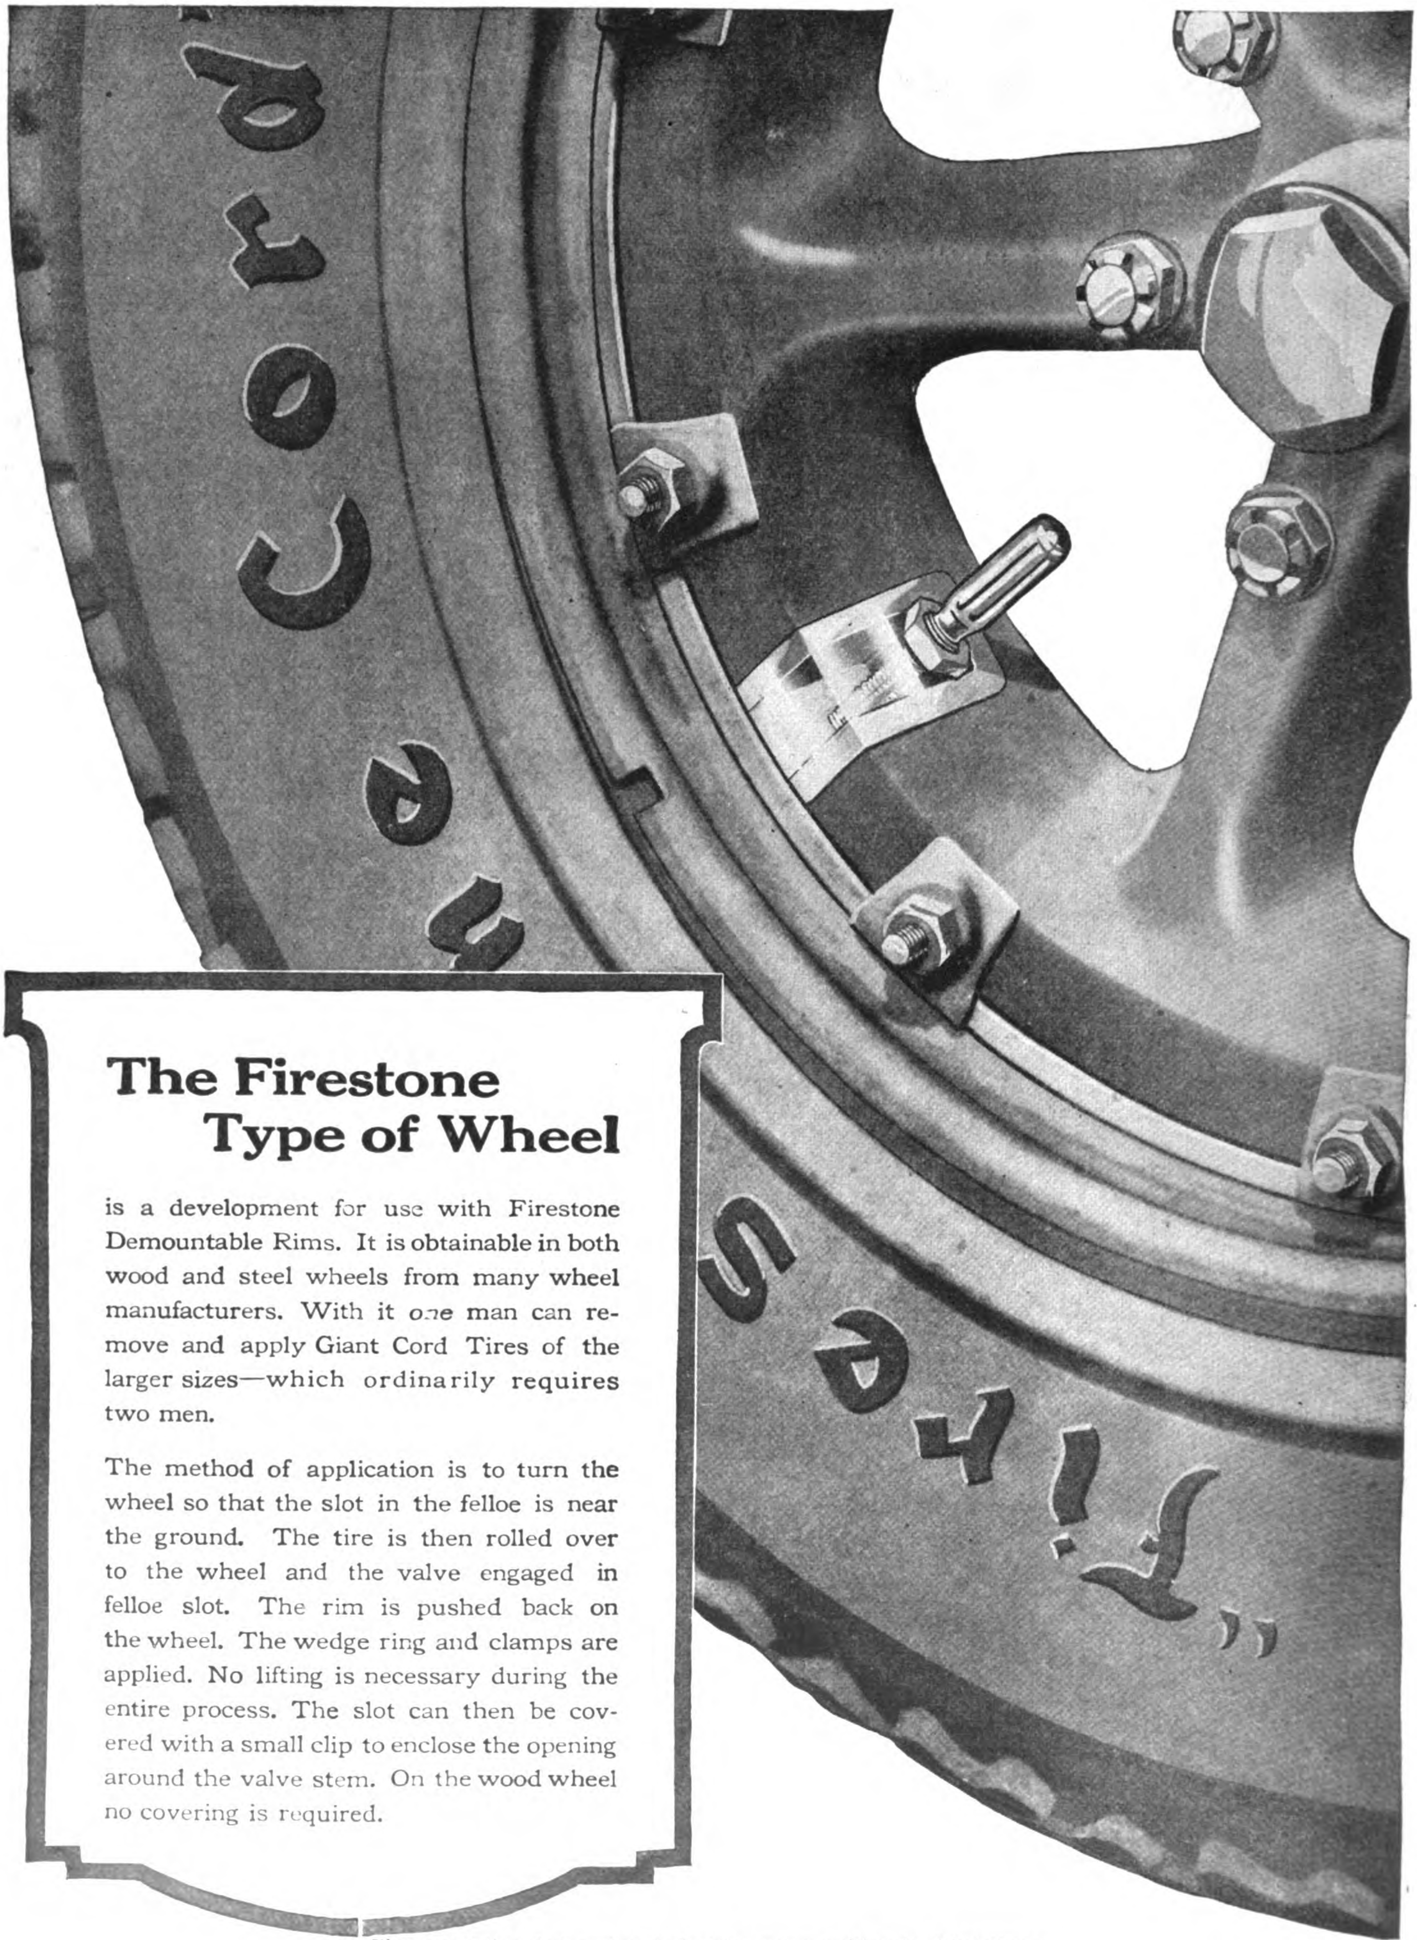
Applicants are requested to write in complete detail in their first letter, the contents of which will be held in strict confidence.

Address—The President—personal, Box 411

AUTOMOTIVE INDUSTRIES



Look at It
NITRO
SUNDERMAN
CARBURETOR
It's so Simple
Simplicity is a necessary feature of a carburetor. The designers of the new NITRO carburetor appreciated this fact, and have succeeded in making the NITRO so simple, so fully automatic in operation, that it is obviously easy to adjust and to understand—it has but ONE adjustment and that one easy to reach. Another reason why the NITRO is the logical carburetor equipment for YOUR new chassis.
Sunderman Corporation, Newburgh, N. Y.

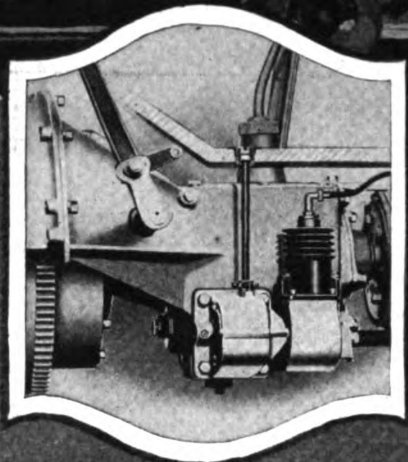


The Firestone Type of Wheel

is a development for use with Firestone Demountable Rims. It is obtainable in both wood and steel wheels from many wheel manufacturers. With it one man can remove and apply Giant Cord Tires of the larger sizes—which ordinarily requires two men.

The method of application is to turn the wheel so that the slot in the felloe is near the ground. The tire is then rolled over to the wheel and the valve engaged in felloe slot. The rim is pushed back on the wheel. The wedge ring and clamps are applied. No lifting is necessary during the entire process. The slot can then be covered with a small clip to enclose the opening around the valve stem. On the wood wheel no covering is required.

FIRESTONE has given to the Motor Truck Industry a new wheel design which puts added efficiency into the use of Giant Pneumatic Tires.
When the demand for speed in trucking centered the interest on the perfection of Giant Pneumatics, Firestone produced the rim which aided so materially the practical use of Giant Pneumatic Tires.
To further aid the industry, Firestone now offers a new thought in wheel design which makes more practicable the removal and application of Giant Pneumatics.
With this combination, it is possible for *one* man to remove the largest tire and apply an *inflated* spare tire in five minutes. It is not necessary that the man have experience to accomplish this result.
Firestone does not build wheels. But the Firestone type of wheel is obtainable from many wheel manufacturers, who have incorporated the Firestone idea in their standard wheels, thus permitting them to carry the Firestone type C Rim.
There are no royalties or restrictions involved in the use of the idea. It is the Firestone hope that the industry may profit by the use of this wheel design. Its success to date indicates that it has great value both to truck operators and drivers.
The Firestone Steel Products Co.
FIRESTONE PARK
AKRON, OHIO



"Both are Passenger Cars"

THE light sport car and the 5th Avenue Bus are both passenger cars—but what a difference! Where the ordinary tire carrying an air pressure of 60 to 90 pounds will do for the passenger car, the heavy bus when it uses pneumatics must adopt the masterpiece of the tire maker's craft, the giant pneumatic with its pressure of from 150 to 175 pounds.

And yet the terrific pressure requirements of this big "passenger car's" tires can be met by the same make of air compressor as has served so well for its little brother—the Kellogg Engine Driven Tire Pump.

KELLOGG MFG. COMPANY
Rochester N. Y.

KELLOGG

Hartford SHOCK ABSORBER

THE TEST

NIGHT driving is a sure test of dependability. Irregularities in road surfaces are hard to gauge. The sledge-hammer blows dealt a car by these bumps hasten it to the junk pile, and are a source of continual discomfort to occupants.

Recommend that your customers protect their cars and themselves by equipping with Hartford Shock Absorbers. Night driving will be made a pleasure, for the Hartford will take a car over the ordinary bumps smoothly and evenly. You will win happy, satisfied customers, who will bring you new friends.

And then figure the net profit to yourself. If you handle this line in addition to your agency, you get a generous profit on the sales of the Hartford plus your original profit on the car you sell.

The Hartford is part of the factory equipment of most of America's finest cars. This, in itself, is proof positive that it is the leader in its field. It has been the leader for fifteen years.

Write us for our dealer proposition and details regarding our national advertising campaign and attractive literature and dealer helps.

The Hartford line includes two other big sellers that it will pay you to stock—**Hartford Spring Bumper** and **Hartford Auto Jack.**

NASH QUADS WIN ARMY SHOW HONORS

Get First and Third Prizes in Sayn, Germany.

From "across the Rhine" comes testimony by the American Army of Occupation of further distinction accorded the famous Nash Quad. Word that two Quads have been awarded first and third prizes respectively in the Divisional Motor Show of the Thirty-second Division has just been received by the Nash Motors Company.

Requirements under which the prizes were awarded were based upon military standards and were very rigid. That the two Quads secured top honors is another tribute to the dependability, durability and performance of the Quad.

Information concerning the outcome of the divisional show came in the form of a letter from Capt. Edward Dayton. The show was held at Sayn, Germany, near Coblenz, and was looked upon by army officers as one of the most important events to be held during the period of occupation.

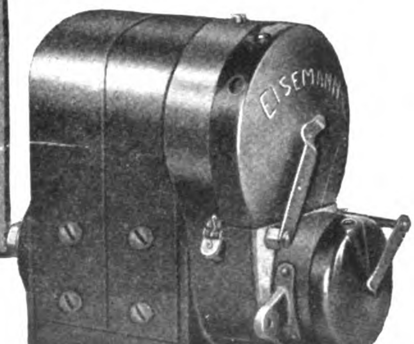
The winning Quad, Capt. Dayton states, had to its credit a record of 5,000 miles, the awards, he says, having been based on the number of miles driven, the mechanical condition and the general appearance.

"The Quads had seen considerable usage," relates Capt. Dayton, "and the men in this organization were especially interested in the outcome."

During the war period the Nash Motors Company built more than 12,500 Nash Quads for military purposes.

Of Course, They're Equipped with the

EISEMANN MAGNETO



The vast majority of all trucks used by our Government in France were Eisemann-equipped—in the Ordnance, Signal Corps, Quartermaster, Ambulance and Medical Departments.

CONSISTENT

CS

DROP FORGINGS

For Every Branch of the Automotive Industry

Careful selection of steel;
New and up-to-date equipment;
Thorough inspection after each operation;
Competent supervision;
Skilled mechanics;
These are the things that enable us to turn out strictly high quality forgings from a fraction of a pound to forty or fifty pounds, either rough, partly machined, or completely machined ready for assembling.

We also manufacture and offer to the trade Electric Alloy Steels in forging bars and billets.

Send us your blueprints for estimates.

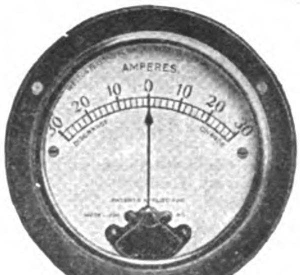
Don't Kill the Joy of Motoring!

If the driver has to worry perpetually over the condition of his storage battery, never knowing definitely whether he is recharging or discharging, there is very little real comfort in motoring. Sooner or later this will react upon the manufacturer. Put a



Weston

MODEL 354 AMMETER

on the Dashboard or Cowl

and a glance will always tell the driver whether he is maintaining the proper condition of his battery. Don't fool with unknown substitutes, which will injure the prestige of your product. Write us.

WAUKESHA MOTOR CO.

WAUKESHA, WIS.

Truck Manufacturers Are Furnishing Detroit Weatherproof Cabs as Standard Equipment.

On motor truck cabs this trade mark is a symbol of highest quality just as it so identifies weatherproof bodies for passenger cars.

Sturdy, roomy, "non-rattling" truck cabs are in universal demand. Comfort to drivers is as essential as warmth, light and good ventilation are to factory operators.

Detroit Weatherproof cabs are light in weight, have ample capacity to seat three husky men, plenty of leg room, doors slide up and down (not on hinges), and the reinforcements result in great resistance to vibration and severe service.

We invite discussion of cabs with manufacturers and distributors of trucks.

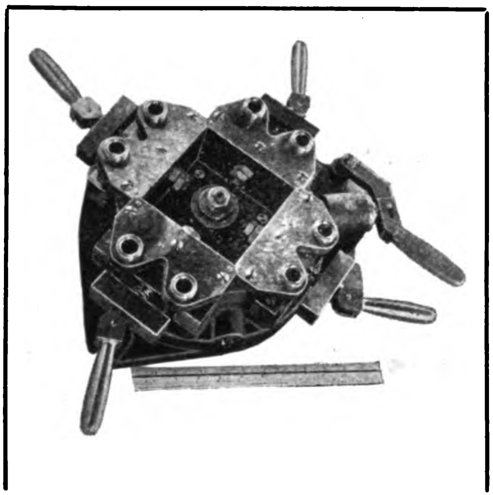
TOOL — TRADE MEHL MADE MARK — SERVICE



A Conference Was Held In Our Offices

A large manufacturer found that his entire product was being held up by the sluggish production of just one part. He came to Mehl with his problem. Mehl pointed to an easy solution.

This Jig Did More Than We Promised

The Mehl-Made solution of this problem was the use of a correctly designed jig—we show it above—which when placed in service did more than we claimed for it. Today Mehl-Made Jigs, Fixtures, Dies, Gages and Special Machines are helping this same manufacturer all over his plant.

The Mehl-Made staff of tool experts is at your service. Call, write, wire or 'phone.

ENGINEERING SERVICE

Designing Department

Large Layout Board used for laying out all work

The Success of Your Production Plan Begins Right Here

If you're going to get into production ON TIME and with all the wheels working smoothly, your special production tools must be **correctly designed!**

We're Tool Engineers—Specialists in Tool designing and building. We **guarantee** delivery on time of **correctly designed** tools for your particular purpose—tools that will not have to be returned because of errors.

Some of the biggest and best Automotive Manufacturers rely upon us for their most important work of this character.

Our Designing Department (shown above) is of a quality and completeness far out of the ordinary. The large "Layout Board" shown is used for laying out all work before starting upon it. Our methods practically preclude the possibility of error.

We can place at your disposal a highly efficient Tool Engineering and Tool Building organization. Beginning with pattern making, every branch of our organization, including selling, engineering, designing, foundry work, heat-treating and actual tool making, is devoted to tools and tools only.
Let us send a representative to tell you about our service with a view to assisting in your tooling for manufacture.

Attention Mr. Arnold, Contract Department.

Dear Sirs-

We wish to extend to you our thanks and appreciation for your successful efforts in locating a Factory for us which could manufacture Ford Front Springs, after all our efforts had failed. This information, which you were able to give us within a few weeks, is very much appreciated, and the Factory is now manufacturing Front Springs for us in large quantities, and the arrangement has proven satisfactory and beneficial to both them and us. We feel sure that it would pay manufacturers to keep in touch with you when they want business.

Thanking you for your assistance, we are

"Yours for Berlin in 1919"

CONTRACT WORK

Manufacturing and Merchandising Opportunities

The items appearing in these columns form a part of the inquiries received by our Contract Work Service Department during the past three weeks. Manufacturers or concerns interested in these or similar inquiries can secure full information as to how this service is operated by communicating with the Contract Work Service Department, Automotive Industries, 239 W. 39th Street, New York City.

6052 Quotations desired on 8" and 3" brass bushings in lots of 1000.

6053 Inquiry received relative to a concern who can handle casting in 500, 1000 and 5000 lots. The casting to be about half the length of a sample on file in this department and is of cast steel.

6058 Manufacturers of electric specialties, located in Chicago, would like to get in touch with concerns who are equipped to manufacture high quality reflectors for automobile lamps. (Silver plated brass reflectors.)

6067 Inquiry received from New Jersey for a manufacturer of spark plugs in small lots, as samples of patent plug.

6068 French interests desire to represent American firms along lines of commercial or industrial relation connected with automotive work.

6072 A Missouri automobile sales company want to get in touch with a firm that will manufacture a blowout patch in quantities.

6073 Builders of high grade bodies are in the market for a quantity of wood carvings which they need for hearse and undertaker wagons.

6074 A New York firm desires to be placed in touch with manufacturers of standard equipment, such as front axles, rear axles, wheels, steering gears, frames, springs, in fact all parts of automobile except radiator, power plant and transmission.

6075 Inquiry received from Syracuse from company desirous of placing work covering forgings (bar) flattened small rounds; screw machine, pins (small) large head cap screws; springs, market spring wire (steel) springs, light wire, wound ⅝ dia. They are desirous of communicating with firms producing finished miscellaneous soft grey iron castings delivery same machined to drawings.

6076 New York concern desire to get in touch with a manufacturer equipped to handle what is known as a security robe rail, which is a two-piece rail, the upper bar being hinged at one end with a lock at the other; parts of this device will necessitate die-casting. They want these turned out in quantities of approximately 5,000 per month.

6078 Connecticut concern want to be placed in touch with gray iron foundries.

6080 Minnesota manufacturers of agricultural implements want to get in touch with a manufacturer in a position to produce a farm tractor in its entirety.

6048 Party owning an audible signal for road vehicles which device is automatic and can be used on commercial as well as on pleasure cars, is looking for manufacturing and merchandising assistance.

6049 Company owning a patented automobile signal, due to lack of funds to carry on the production of same, is looking for manufacturing and merchandising assistance. The signal is so constructed that it can be seen in daylight or dark, from the right or left and from the front or rear.

6050 Inquiry received relative to manufacturers who might be interested in a radiator that is non-breakable which is claimed to be far superior to the ordinary radiators in that it will freeze but will not burst, is more accessible for repairs and has enlarged cooling surface.

6051 Party located on the Pacific Coast is looking for manufacturing and merchandising assistance in connection with a circuit breaker and distributor on which he owns a patent; the system he claims is very simple.

6054 The owner of a patented baggage rack which folds down and makes a regular mat foot scraper when not in use as luggage carrier, wants to dispose of same on either a royalty basis or sell outright. It can be made of woven wire matting, cast iron or aluminum.

6055 Interests back of this inquiry are desirous of getting in touch with manufacturers who would like to investigate a tractor truck for railway passenger cars. Possibilities ahead are almost unlimited. Consultation is invited.

6056 This inquiry has to do with a shock absorber, the owner of which is looking for a manufacturer to place same on the market. This shock absorber is a new and highly improved method in Ford suspension.

6057 Party located at Wisconsin owning patents on a new automobile tire which he claims will outlast any tire on the market to-day, also that the tire is non-skid and blowouts are excluded, is desirous of disposing of the patents on a royalty basis or some other satisfactory arrangement.

6059 The holder of patents on an ignition lock for automobiles that is applicable to 90 per cent of the American cars, (all those using battery ignition) is desirous of getting in touch with some one who will manufacture the lock on a royalty basis or by purchasing the lock outright, or is willing to make any arrangement satisfactorily to the manufacturer, whereby he will net some profit.

6060 Owner of a patented differential and lock for motor vehicle drive axle is looking for manufacturing and merchandising assistance.

6061 This proposition has to do with an internal combustion engine, interests back of which are ready to place same on the market and want to get in touch with manufacturers.

6062 Inquiry received from party owning a patented kerosene and gasoline carburetor who wishes to sell same either outright or take small cash payment with the balance in royalties.

6063 Manufacturing and merchandising assistance required to place on the market an adjustable radiator fan.

6064 This proposition covers a safety stop on any auto in case of failure of brakes to hold on going up-hill when stalling motor or failure of getting into second or first gears, owner of which is looking to dispose of same and will consider any kind of an arrangement.

6065 A roller-bearing, the principal object of the invention being to provide an improved form of anti-friction bearing so arranged that both rotary and thrust friction will be reduced, party owning patents on this device is looking for a firm that will take this over on a royalty basis, or buy it outright.

6066 A New Yorker wants to enter into a satisfactory arrangement with a manufacturer in regards to disposing of trademark on a valve grinding compound with material and equipment necessary to commence manufacturing at once, would consider entering into a royalty arrangement.

6069 Tractor engineers have developed a small creeper type tractor which they wish to place on a royalty basis. Power steering, no brakes used and no loss of power when steering, three speeds forward and reverse, 18-10 h.p., thoroughly covered by eight patents and patent applications. Will submit proposition and demonstrate tractor to responsible manufacturers.

6070 This inquiry has to do with a ground gripping device for vehicle wheels which the owner wants to dispose of either outright or on a royalty basis.

6071 The owner of a new spark plug the object of which is to provide a novel means by which carbon may be kept from accumulating on the electrodes, and also to provide a way to prime an internal combustion engine through the spark plug, wants to get in touch with manufacturers in a position to finance the proposition.

6077 The owner of a positive gear drive transmission wants to sell the patents, or license its manufacture on a royalty basis.

6079 A wheel and rim corporation located in Ohio are seeking arrangements for the manufacture of a suspension wheel in a larger way, on royalty or some other business basis.

6081 New York interests are looking for a plant to manufacture a heavy duty 6" bore motor. It has been designed for use on rail cars, also for marine use.

6082 Owner of a permanent dust-proof grease-tight casing for steering connections is open to any equitable proposition, for sale outright, for manufacture and marketing on a royalty basis, or for marketing only.

Manufacturers Looking for Help

Manufacturers looking for men of ability such as Engineers, Salesmen, Mechanics, etc., etc., will always find it to their advantage to use these columns. The Automotive Industries is read almost daily by the men who know and are accomplishing things daily. The men worth while will read your advertisement in this paper. Try it for results.

SALESMAN

"Where can we locate a live wire?" was the query of a well-known New York house. The expert salesman keeps in close touch with the automobile authority of the industry. Your message therefore in this paper will bring results.

Your Patented Automobile Accessory Manufactured

Many practical accessories are never placed on the market, due either to lack of manufacturing facilities, merchandising organization, or capital.

There are many automotive concerns prepared to consider and take hold of worth-while opportunities.

It is the work of this Department to bring these interests together.

There is no charge for this service.

Send blueprints, specifications and full information as to the kind of material and manufacturing equipment necessary to manufacture the article in question.

It is also important that you state whether you are in a position to finance the proposition or if it is to be manufactured on a royalty basis.

For co-operation along the above lines address the

AUTOMOTIVE INDUSTRIES Service Department, Contract Work
239 WEST 39th STREET, NEW YORK CITY

OF COURSE no big plant would be without Oxweld Service. Important equipment will break. They must have Oxweld to safeguard production speed and to keep down "idle-time" losses.

"The one-man machine shop," as Oxweld Equipment is called, is equally vital to small plants. Reclaiming broken and defective parts—building up worn surfaces in the quickest, most economical way.

The Oxweld Injector Type Blowpipe does its work with greater speed and certainty, and at less cost, than any other welding or cutting device.

Write for the Bulletins applying to your business.
They're interesting.
